On the Indications and Contra-Indications for the Removal of the Gall Bladder.—Mayo Robson (*Brit. Med. Journ.*, Feb. 24, 1906) protests against the indiscriminate removal of the gall-bladder in all cases in which an operation on the bile passages is called for. As bile is constantly being formed at a rate of one ounce per hour, if the gall-bladder is removed, its reservoir function is replaced, as has been seen in some cases, by dilatation of the common duct. This must necessitate back pressure on the secreting part of the liver, and possibly biliary absorption. Mayo Robson analyses his fifty-seven cases in which cholecystectomy was necessary. The indications for this operation are: (1) Cancer or other new growth where the disease is local or limited. (2) In contracted and useless gall-bladder, the result of repeated attacks of cholecystitis. (3) In dilated and hypertrophied gall-bladder resulting from obstruction in the cystic duct; (a) always if resulting from stricture, (b) usually if resulting from impacted gall-stones with ulceration, (c) usually if resulting from kinking of cystic duct and adhesions. (4) In phlegmonous or gangrenous cholecystitis. (5) In empyema, calcareous degeneration, and mucous fistula of the gall-bladder. (6) In gunshot or other serious injuries of the gall-bladder and cystic duct. The author finds that a firm sandbag under the patient at the liver level brings the common and hepatic ducts several inches nearer the surface. The incision is over the middle of the right rectus, and when further exploration is necessary the incision is prolonged, not downwards as formerly, but upwards as high as possible between the ensiform cartilage and the right costal margin. By lifting the lower border of the liver an almost straight passage is found from the fundus of the gall-bladder to the entrance of the bile duct into the duodenum. The surgeon has under his eye the whole length of the duct with the duodenum and head of the pancreas. The gall bladder is removed by dividing the cystic duct between two forceps near the common duct. Ligation of all bleeding points is important, as in jaundice cases the compressed and unligatured vessels are apt to bleed subsequently.

S.

Perinephritic Abscess, Diagnosis, and Treatment.—In a paper on this subject, Dr. Ramon Gutieras (*New York Med. Journ.*, Jan. 27th, 1906) describes fifteen cases of this affection, which he had treated, and draws from them the following conclusions: (1) Many more cases of perinephritic abscess are due to suppurative renal disease than is generally supposed, a fact which will be proved with the rapid strides that are now being made in renal surgery. (2) Traumatism, exposure, and similar influences to which

primary perinephritis is attributed are not so important as many observers have claimed. They are often vaguely given as causes, when they are simply coincidences, or the active causes of rupture of already existing abscesses in the kidney or neighbouring structures. (3) It is important, though difficult, to determine the source and course of the pus. Therefore, before the operation, pus should be looked for in the common urine and the separate urine by the ureteral catheter. During the operation the surgeon should try and determine whether the kidney is the source, and, if not, what tissue or organ is. It is equally important to discover the road taken by the pus, as it indicates where a counter opening should be made, and the further treatment of the case for complications. (4) The elements of success in operations for perinephritic abscess may be summed up as follows: Early incision and evacuation before the pus has had time to burrow extensively; thorough exploration without timidity, opening the kidney and exploring the ureter if need be; thorough drainage down to the deepest part of the sac by means of large soft rubber drains or gauze, the drain being kept in place until a well-formed sinus exists down to the deepest part of the cavity; nephrotomy, nephrostomy, or nephrectomy should be performed if indicated at the time of the operation or later on if necessary. G.

Subcutaneous Pelvic-ureteral Lumbar Implantation.—In a paper on the treatment of the ureter after nephrectomy, Dr. Ernest Gallant (*American Medicine*, Jan. 13th, 1906) asks the question: Is the removal of ureter advisable, desirable, or necessary? He himself prefers to treat the ureter in the following way: The ureter is cut across about one inch above the junction of the ureter and the pelvis of the kidney, the renal vessels are then ligatured and that organ removed. The funnel-shaped opening into the ureter is then sutured to the lumbar fascia at the lower end of the wound, in such a way that the mouth is not exposed on the skin surface, but opens into the subcutaneous fatty tissue; when the discharge ceases the skin readily closes over the outlet and buries it. In cases of tuberculous kidney or pyonephrosis, without ureteral obstruction, it may be well in female patients to resect the vesical end of the ureter through a vaginal incision, close off the vesical end of the tube, and suture the proximal end of the ureter into the vaginal wound, and so provide free drainage. Dr. Gallant claims the following advantages for this method of lumbar implantation: (1) It avoids the additional risk of immediate ureterectomy; (2) it secures free drainage and maintains an opening through which drugs may be introduced to hasten retrograde changes in the ureter; (3) the opening being beneath the skin does not prevent primary union, should mucus or pus form they cannot accumulate or burrow in the retro-colonic space; they are easily recognised and let out through a small skin incision; (4) the presence of a drainage tube in the ureter, with or without the vaginal implantation, does not interfere with the patient getting out of bed at an early date after the operation. G.

Radical Operation for Dacryocystitis.—Fromaget, of Bordeaux (*Société Franc. d'Ophthal.* May, 1905) considers that cases of chronic dacryocystitis, which are so intractable as to call for any of the various radical methods of treatment that have been hitherto recognised as suitable, had better be treated by performing at one time the three operations of extirpation of the lacrymal sac, curetting of the nasal duct and removal of the lacrymal gland. M.

Ophthalmia Neonatorum of Lacrymal Origin.—Pechin (*Société Franc. d'Ophthal.* May, 1905) points out that there are cases of conjunctivitis in new-born infants with muco-purulent secretion in which the usual remedies prove useless. These cases are often found to be due to lacrymal obstruction, or in some cases even to eversion of the punctum in very fat babies. In such cases it is necessary to remove the obstruction by syringing or passage of a probe. M.

The Sub-Mucous Caustery Treatment of Hypertrophy of the Inferior Turbinates.—S. J. Kopetzky, New York (*The Laryngoscope*, Oct., 1905) introduces to his readers a form of sub-mucous caustery which has given good results in his hands. The instrument is made of an alloy consisting of "about 30 per cent. platinum iridium." This mixture of metals has sufficient stability to retain its shape and permit its introduction into the tissues while cold. The caustery end is one and one quarter inches long, one quarter inch broad, and as thin as is consistent with rigidity. The handle is of metal and fits any standard caustery handle. Kopetzky's object is to attack the centre of the inferior turbinal rather than the mucous surface. He claims the following advantages for his method: (1) Less cocaine required for anaesthesia, (2) after effects and reaction nearly absent, (3) danger of adhesions forming absent, (4) no scabbing or crustation, (5) no destruction of superficial epithelium or functioning structures brought about, (6) the method produces a contraction of the turbinal body, without destroying its contractile tissues, (7) results have proved uniformly good. M.

The Treatment of Atrophic Rhinitis by an Oro-nasal Canula.—S. Iglauer (*The Laryngoscope* Nov., 1905), calls atrophic rhinitis "das Schmerzskind der Rhinologie" and considers any treatment which gives any relief to be worthy of record. He briefly reviews the recent literature as to the origin and treatment of this disease. It occurred to Iglauer that the saliva, being a secretion foreign to the nose, might perhaps exert a stimulating or irritating effect on the mucosa and might thus reproduce one of our therapeutic endeavours. There is also the possibility that the bacteria of the mouth might act injuriously on those found in ozena. With a view to bringing the saliva in contact with the nasal cavities, the author devised the plan of making an oro-nasal fistula through which the patient might irrigate the nose with his own saliva. With this object in view he anaesthetises the mucous membrane and periosteum of the hard palate with cocain and adrenalin, then exposes the bone by means of knife and periosteotome, about 1 cm. from median raphé and with a bone drill (5 mm.) a hole is bored into the nose. To avoid stripping up the nasal mucosa with the drill, it should be nicked with a curved bistoury as soon as the drill has reached the membrane. To establish a permanent opening a rubber-flanged tube has to be retained until the bone and membranes have healed, when a permanent silver canula is inserted. This healing process is often tedious—four and a half months in one of the first cases. Through this canula the patient frequently squirts or sprays saliva over the mucous membrane of the nose. The oro-nasal opening does not interfere with phonation. Three cases are recorded from which we gather that symptoms, crusts and fœtor at least were alleviated. Iglauer presented the paper in the hope that some of his colleagues would give the treatment a trial. M.

Primary Lympho-Sarcoma of the Tear Gland.—Gondron (*Société Franc. d'Ophthalmologie*, May, 1905) records a case of a tumour growing under the upper orbital margin of a man, æt. 18. The tumour was removed by Kroenlein's operation and proved to be a lympho-sarcoma springing from the capsule of the lacrymal gland. Recurrence took place a few months after the removal with a fatal result. M.

NOTE.—A summary will appear each week in the following sequence:—

- (1) "*Recent Medical Literature.*"
- (2) "*Recent Surgical Literature.*"
- (3) "*Recent Gynaecological and Obstetrical Literature.*"
- (4) "*The Recent Literature of Physiology, and Pathology.*"

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

DR. J. BEARD (Liverpool).—Your paper on "Profuse Desquamation in Typhoid Fever" is marked for early insertion.
OBSERVATION.—Physician: "Has the patient followed my prescription, nurse?"—Nurse: "No, doctor; if he had he would have broken his neck, for he threw it out of the window."

ADVICE TO YOUNG ADVERTISEMENT WRITERS.

"In preparing copy for patent medicines you will endeavour not so much to prove the disease curable as to convince the reader that he has it." This extremely suggestive and witty maxim is taken from the *Business Man's Magazine* (N. York).

A SUBURBAN PRACTITIONER.—The cases of infectious diseases within the area of the Metropolitan Asylums Board are considerably fewer than at the corresponding period of last year.

MR. J. S. SUTTON.—The diminution of the birth-rate continues without intermission, but you overlook in your comparison that the death-rate has decreased to a much larger extent.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 7th.

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Mrs. Scharlieb, Dr. Lockyer, and Dr. A. Routh. Paper:—Mr. J. D. Malcolm: Peritonitis and the Staphylococcus Albus.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20 Hanover Square, W.).—5 p.m. Paper:—Dr. C. Watson (Edinburgh): Observations on Diet with Special Reference to a Meat Diet and Uric Acid (with lantern demonstrations).

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Hunterian Lecture:—Prof. W. Howard: Phlebitis and Thrombosis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Cheapside Street, W.C.).—4 p.m. Mr. J. Berry: Clinique. (Surgical). 5.15 p.m. Lecture:—Dr. L. Brown: Acid Intoxications.

THURSDAY, MARCH 8th.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8 p.m. Card Specimens will be shown by Mr. S. Stephenson, Mr. A. Levy, and Mr. P. Smith. 8.30 p.m. Papers:—Mr. C. Worth: Hereditary Influence in Myopia.—Mr. J. H. Parsons and Mr. G. Coates: Further History and Pathological Examination of a Case of Microphthalmia associated with Congenital Tumours previously shown by Mr. Parsons.—Mr. P. Smith:—A Scotometer for the Rapid Diagnosis of Incipient Glaucoma and other purposes.

BRITISH GYNECOLOGICAL SOCIETY (20 Hanover Square, W.).—7.30 p.m. Special General Meeting. 8 p.m. Specimens will be shown by Dr. Jellitt and Mrs. Scharlieb. Papers:—Dr. Jellitt: Notes on two rare conditions met with in the Pelvis during Operation.—Mrs. Scharlieb: The Advantages of the Abdominal Route in Operations for Cancer of the Uterus.

ROYAL COLLEGE OF PHYSICIANS OF LONDON (Pall Mall East).—5 p.m. Milroy Lecture:—Dr. W. H. Hamer: Epidemic Disease in England—the Evidence of Variability and of Permanency of Type.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Cheapside Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Lecture:—Mr. A. E. Tubby: Surgical Diseases of Children.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—8 p.m. Dr. M. Dockrell: The Relation between Clebsitz, Keloid, Scleroderma, and the Treatment of each. (Chesterfield Lecture.)

FRIDAY, MARCH 9th.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m. Papers:—Dr. H. French and Mr. C. B. Ticehurst: A Note upon the Relation of Traumatic Diabetes Insipidus to Glycosuria.—Dr. F. Buzzard and Mr. J. Cunnling: A Case of Post-traumatic Hemorrhage from the Superior Longitudinal Sinus without Fracture of the Skull, Operation and Recovery.—Mr. J. E. Spicer (introduced by Dr. P. Kidd): An Unusual Case of Dilatation of the Stomach following Hour-glass Contraction.—Dr. A. E. Garrod and Dr. Langmead: Associated Malformations, including Transposition of Viscera.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Hunterian Lecture:—Prof. W. Howard: Phlebitis and Thrombosis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Cheapside Street, W.C.).—4 p.m. Dr. L. Lack: Clinique. (Throat.)

Vacancies.

Birkenhead and Wirral Children's Hospital. Woodchurch Road, Birkenhead.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to F. W. Archer, 25, Storeton Road, Birkenhead.

Bradford Children's Hospital.—House Surgeon. Salary £100 per annum. Applications to C. V. Woodcock, Secretary.

Bristolington House Private Asylum, Bristol.—Assistant Medical Officer. Salary £180 per annum. Applications to the Resident Licentiate.

British Ophthalmic Hospital, Jerusalem.—Assistant Surgeon. Salary £300 a year, with residence. Applications to R. Brudenell Carter, F.R.C.S., 76 South Side, Clapham Common, S.W.

Corporation of Sheffield Fever Hospital.—Junior Assistant Medical Officer. Salary £120 per annum, with board, lodging, and washing. Applications to H. Bayer, Town Clerk, Town Clerk's Office, Town Hall, Sheffield.

Metropolitan Hospital.—Casualty Officer. Salary £150 per annum. Applications to Charles H. Byers, Secretary.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-upon-Trent.—Senior House Surgeon. Salary £100 per annum, with furnished apartments, board, and washing. Applications to Albert E. Boyce, Secretary and House Governor.

Parish of Saint Leonard, Shoreditch.—Medical Officer to Cottage Homes at Hornchurch, Essex. Salary £130 per annum. Applications to Robert Clay, Clerk to the Guardians, Clerk's Office, 213 Kingsland Road, N.E.

The Asylums Committee of the London County Council.—Assistant to the Pathologist of the London County Asylums. Salary £250 per annum. Applications to H. F. Keene, Clerk of the Asylums Committee, London Asylums Committee Office, 6 Waterloo Place, London, S.W.

The London Hospital Pathological Institute.—Director. Salary £500 per annum. Applications to Munro Scott, Warden, The London Hospital Medical College, Turner Street, Mile End, E.

Walsall and District Hospital, Walsall.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to the Chairman, Mr. E. J. Brookes, Leicester Street.

West Kent General Hospital, Maidstone.—House Surgeon. Salary £120 per annum, with board and residence. Applications to the Secretary.

Appointments.

COBENS, WILLIAM BURROUGH, L.R.C.P.Lond., M.R.C.S., Medical Referee under the Workmen's Compensation Acts, 1897 and 1906, for Weymouth County Court, in County Court Circuit, No. 55.

COXON, STEPHEN A. T., L.D.S.R.C.S.Irel., Honorary Dental Surgeon to the West Norfolk and Lynn Hospital.

FINCH, G., M.R.C.S., L.R.C.P.Lond., Junior House Surgeon at the Radcliffe Infirmary, Oxford.

HAMILTON, A., L.R.C.P., L.R.C.S.Éd., Certifying Surgeon under the Factory and Workshop Act for the Ashton-under-Lyne District of the county of Lancaster.

HORNER, N. G., B.A.Cantab., M.R.C.S., L.R.C.P.Lond., Assistant House Surgeon at the Westminster Hospital.

MACGILVRAY, W. J., HOOKER, L.R.C.P., L.R.C.S., L.M.Éd., L.F.P.A., L.M.Glasg., Medical Officer to the Royal Liver Friendly Society for Manchester, Salford, and District.

MACILWAINE, J. E., M.D.R.U.I., Certifying Surgeon under the Factory and Workshop Act for the North Belfast District of the counties of Antrim and Down.

MALLAM, ERNEST, M.B., B.S.Oxon., Certifying Surgeon under the Factory and Workshop Act for the Oxford District of the counties of Oxford and Berks.

MULLIGAN, E., L.R.C.P. and S.Irel., Certifying Surgeon under the Factory and Workshop Act for the Foxford District of the county of Mayo.

PARK, J. R. A., L.R.C.P. and S.Éd., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Dukinfield District of the county of Chester.

PURDON, E. B., L.R.C.P. and S.Éd., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the South Belfast District of the counties of Antrim and Down.

RISSEN, E. RUSSELL, L.S.A., Certifying Surgeon under the Factory and Workshop Act for the East Hlsley District of the county of Berks.

SHEPPARD, A. L., M.B., B.S.Durh., Senior House Physician at the Bristol Royal Infirmary.

Births.

CAZALET.—On March 1st, at Sutton, Surrey, the wife of Grenville Wm. Cazalet, L.R.C.P.Lond., M.R.C.S.Eng., of a son.

GAVIN.—On March 2nd, at the Medical Mission House, Anand, India, the wife of Nell M. Gavin, F.R.C.S.E., of a daughter.

GREENE.—On Feb. 25th, at 124 Crossbrook Street, Cheshunt, Herts, the wife of William A. Greene, M.R.C.S., of a daughter.

MAINGAY.—On March 3rd, at 33 Queen Street, Scarborough, the wife of H. B. Maingay, F.R.C.S., of a son.

MASTERMAN.—On Feb. 18th, at Jerusalem, the wife of E. W. G. Masterman, F.R.C.S., D.P.H.Cantab., of a daughter.

SOUTH.—On Feb. 28th, at the Manor House, Moreton, Dorset, the wife of Fleet-Surgeon Henry Erskine South, R.N. (retired), of a daughter.

Marriages.

PARRY JONES—THORN.—On March 3rd, at the Old Parish Church of St. Mary's, Ealing, Lieutenant W. D. Parry Jones, elder son of the late W. D. Jones, M.D., of Rhianfa, Ruthin, to Catherine, younger daughter of C. Spencer Thorn, solicitor, Caerwys.

Deaths.

CHARLES.—On March 2nd, at Flushing, Cornwall, Surgeon-General Thomas Edmondston Charles, late of the I.M.S., M.D., LL.D.Éd., F.R.C.P.Lond., K.H.P., aged 71, late of Calcutta.

DEAN. On March 4th, at 4 Rosary Gardens, South Kensington, the residence of her grandparents, Anne, the only child of Henry Percy Dean, M.S., F.R.C.S., 89 Harley Street, London, aged 1½ year.

HERBERT.—On March 2nd, at 6 Elliott Terrace, The Hoe, Plymouth, Deputy-Surgeon-General Henry Carden Herbert, M.D., F.R.C.S.I.

LONGTON.—On Feb. 27th, at Brown House, Ulverston, Edward John Longton, M.D., J.P., late of The Priory, Southampton, aged 76 years.

TUCKWELL.—On March 2nd, at 84 High Street, Oxford, Henry Matthews Tuckwell, M.D., F.R.C.P., in his 72nd year.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 14, 1906.

No. II.

NOTES AND COMMENTS.

Increase of General Paralysis.

THE constant increase of insanity in the United Kingdom is alarming. Professor Clouston, of Edinburgh, has recently drawn attention to the large increase of patients suffering from general paralysis. Last year the number of female asylum patients admitted under his care for that particular malady for the first time on record exceeded that of the men. Further, the rate of general paralysis was 18.5 per cent. of asylum patients as against 5 per cent. in private practice. From these figures, Dr. Clouston augurs unfavourably as to the social life of the class from which hospital patients are drawn. Yet behind it all lies the inspiring hope that general paralysis will ere long be treated as a curable if not an absolutely preventable disease. At any rate, so careful and distinguished an authority as Dr. Clouston now endorses the theory of Dr. Ford Robertson that the terribly malady in question is the result of invasion of the body by a specific pathogenic microbe.

Alcohol and Insanity.

ALCOHOL always figures in the indictment against the causes of insanity. Dr. Clouston says in his report:—"It is incontestable that our alcoholic insanity rate is still far too high. An educated public opinion and healthy conscience are still needed in a much higher degree to avoid and resist the hurtful social evil of excess in drink. The latest researches into the subject of heredity tend to prove that its results do not end with our generation, but produce physical and mental degeneracy in the descendants of those who destroy their reason by excessive drink. There is much room for the educator, the religionist, and the legislator in this matter. The medical man and the psychological scientist are, as the question is more carefully studied, more and more compelled by the facts of their experience to warn people in regard to the present and far-reaching dangers of alcoholic excess."

The Census of the Empire.

A GREAT and historic blue-book was on Thursday last presented to Parliament by the President of the Local Gov. Bd. It gives, in a way that has never been done before, a bird's-eye view of the vast empire which—in the words of the report—"extends to every continent and climate, and includes representatives of practically every race, creed, language and caste." The present is the first comprehensive and authoritative official summary of the facts of the case. The British flag floats over a fifth of the land-surface of the globe. It dominates some four hundred million human beings, of whom only fifty-four millions are whites, and only fifty-eight

millions are Christians. Well may the imagination stagger at the vastness of this great burden! There are about 208 millions Hindu subjects, 94 millions Mahometan, 12 millions Buddhists, and 23 assorted non-Christian religions. Naturally, this vast collection of figures will furnish much valuable material to the medical statistician.

Racial Infirmities.

SOME of the facts are hardly in accordance with established beliefs. We find, for instance, that deaf-mutism is not more frequent among the Mahometans, in spite of their consanguineous marriages, than among the Hindus, who avoid intermarriage. It would be of great interest from the medical point of view to obtain figures relating to imbecility, bodily deformities, and nerve diseases among the Mahometan population. The worst of official statistics is that they are apt to stop tantalisingly short of the facts when one refers to them. To know that deaf-mutism is not relatively common among our Mahometan subjects is simply to whet the appetite for more information as to the important group of consanguineous degenerations. One important fact emphasised by this blue book is that taking together the lunatics and imbeciles and the feeble-minded, the proportion in nearly all the colonies is much below that at home. Why is the mother country going mad?

Hospital Out-Patient Abuse.

THE Metropolitan Hospital Sunday Fund whitewashes the hospital authorities, and declares there is no abuse of the out-patient departments. Henceforth let the general practitioner know once and for all that his grievance against hospital competition is a vain phantom—for lo! the Sunday Fund, through its professional philanthropists and its urbane consultants, tells him that there is practically no abuse. The Hon. Sydney Holland, most amiable of enthusiasts, denies the existence of anything of the kind. All the talk about abuse of hospitals, quotha, comes from people not connected with them. What does that sarcasm mean? As a matter of fact, the complaint comes mainly from medical men who are deprived of legitimate fees by the indiscriminate relief granted by hospitals to persons capable of paying private practitioners. That is the gist of the whole charge. So that the Hon. Sydney Holland is strictly accurate when he says that the protest comes from persons unconnected with the hospitals. The average medical man ceases his connection with hospitals when he has become qualified, and has perhaps held a resident post or two. Does Mr. Holland remember how his challenge to prove abuse of the London Hospital was taken up by an East London Medical Society and proved? The money problem is all

important to the struggling practitioner. To Mr. Holland it means raising half a million or so for the charity in which he is interested on the one hand, and on the other charging every poor patient a few pence towards cost of relief.

LEADING ARTICLE.

THE DAILY MAIL AND ADVERTISEMENTS.

LAST week we said that we proposed to draw attention to the type of quack advertisement that appears in different organs of the daily press, and this week we proceed to glance at some of those in the columns of the *Daily Mail*. Taking at hazard a recent copy of this paper, we find a crop of these delectable and informing announcements as luxuriant and as misleading as that in any of its contemporaries. The first thing that catches our eye is a two half-column puff of the virtues of Bile Beans. A large portrait adorns the advertisement, and the words, "Made helpless by Rheumatism" are printed in leaded type immediately beneath. Then comes a short dissertation on the pathology of rheumatism, and the ability of Bile Beans to "expel" acid from the blood and correct this malady by virtue of its "unique vegetable composition." A long statement of the usual grandiloquent type, asserted to be the production of Mr. Thomas Coxhill, gardener, of 78, Northfield Road, Harborne, Birmingham, follows, and, as might be guessed, the unfortunate Coxhill, after being under doctors innumerable for twelve years, finally found salvation from muscular rheumatism by means of Bile Beans, which were brought to his notice by the proverbial neighbour. According to analysis, this "world's most successful tonic-alterative" consists of cascara, rhubarb, liquorice, and oil of peppermint, coated with gelatine, and anybody who is fool enough to believe that doctors innumerable would fail to know of the specific value of these simple drugs if they were possessed of the specific value claimed by the proprietors of Bile Beans, can only be the victim of such reiterated falsehoods as quack-medicine vendors commonly tell to disparage the medical profession and prejudice their customers against medical science. To push forward this cruel work, the *Daily Mail* does not hesitate to sell space in its columns and to fill the pockets of its proprietors. If any doubt existed as to the nature of Bile Beans and the character of their owners, they were laid to rest by the recent exposure in Court, and by the words of the judge, who, having heard the evidence for and against this "world's most successful tonic alterative," refused to be any party to protecting a preparation where such was pushed forward by a tissue of falsehoods. In the same issue of the *Daily Mail* is an advertisement, garnished also with portraits of patients and copies of letters asserted to have been received from them, of a Professor Keith-Harvey's treatment for deafness. In it this "Professor" says: "If you are a sufferer from Deafness or Head Noises, and desire a complete and permanent cure, write to Professor

Keith-Harvey for Pamphlet fully describing an entirely new self-applied method which he will send you gratis and post-free on mentioning '*Daily Mail*.'" Here it will be noticed that though the individual who touts for innocents does not actually promise a complete and permanent cure, there is the same alluring *suggestio falsi* about the specious phrase used as there is about the words, "Free to the Deaf," by which the advertisement is headed. What deaf person does not wish a "complete and permanent cure," we wonder, and what is there free about the Keith-Harvey process except the precious pamphlet? On one page of the *Daily Mail* that we have before us are two advertisements of drugs for the hair—one of the so-called "Capsuloids," and the other of a certain Paul Lind, who, like his brother, Keith-Harvey, calls himself "Professor," without specifying at which University he attained the distinction. It is interesting to note that the statements contained in the "Capsuloids" and Paul Lind advertisements are mutually contradictory. The learned Professor by means of his liquid is able to stimulate the "pigmentary glands" of hair and thus cause "a true and permanent alteration in the natural shade." If he reads the "Capsuloids" advertisement he will learn what even his university apparently failed to teach, namely, "Nothing can be any good for hair which is falling out or prematurely grey except Capsuloids, because harmful germs which injure the hair can only be gotten at through the blood, and the only remedy which can reach them through the blood is Capsuloids. It is utterly useless to rub stuff on the scalp." Surely it is obvious to anyone that if both of these statements are not lies, at least one of them must be. Then there are advertisements of "Veritas" Rheumatism Rings, Sloan's Liniment, Vitalia, Coleman's Nerve Pill, Eadie's Gout Pill, a Freckle cure, a "Depression" remedy, Bravais Iron, &c., besides two systems for obtaining beauty and strength by exercises, and odd advertisements of a similar character. In fact, it may safely be said that the quack advertiser is the back-bone of the *Daily Mail*, and from what we have seen, so long as he pays the *Daily Mail* is quite careless as to whether what he says is true, half-false, or wholly a lie. If it is by money gained in this way that affluence, political influence, and power are attained, it may not be a bad thing that we have a House of Commons bent on social reform.

Medical Postal Packets.

At the Middlesex Sessions recently John Melinger, surgical and medical appliance maker, of New Southgate, was indicted for sending 341 postal packets containing improper prints. Sir Ralph Littler the chairman, addressing the grand jury, said it was the first case of its kind to come before a jury, although the Post Office Act under which the proceedings were taken had been in existence twenty-one years. The circular to which objection was taken dealt with a subject that had been written upon by scientists and divines, and the opinions of many were cited. The trade carried on by the accused, said the chairman, was absolutely legal. The grand jury threw out the bill, and the accused was discharged.

NOTES ON CURRENT TOPICS.

Medical Men and the Conveyance of Infection.

THE decision in the case of *Crier and Wife v. Hope and Currie* last week in the King's Bench is of the utmost importance to the medical profession. The defendants, two medical men practising at Hanwell and West Ealing, were sued for damages for alleged negligence on the part of Dr. Currie, which resulted in his communicating scarlet fever to the female defendant in her confinement. The only weak point in the defendants' case was that Dr. Currie appears to have denied that he was at the time of the confinement attending any scarlet fever cases. The decision that all reasonable precautions had been taken and the dismissal of the claim is fortunate for the public at large, as otherwise it would be impossible to continue ordinary medical practice. Medical men have to attend infectious cases at any time of the day or night. They have also to bring children into the world at frequent intervals. They themselves have to take the risk of infection, and so, to put it somewhat bluntly, must their patients. At the same time, with the precautions as to clothing and antiseptics taken by every responsible medical man, the risks of conveying infection are reduced to a minimum. Were it otherwise, the whole country would be continuously decimated by communicable diseases. Were responsibility for chance infection imposed on medical men, there would of necessity arise a special set of practitioner for midwifery alone and another set for infectious diseases alone. Who would pay them? The present all-round practitioner is rewarded on a starvation scale.

Condensed Milk.

A good deal of capital is being made in certain quarters out of some remarks that occurred in a recent lecture by Dr. Edward F. Willoughby at the Institute of Hygiene on "Popular Foods." In the course of that lecture it was said that coroners incurred a grave responsibility by sweepingly and indiscriminately condemning condensed milks as food for infants, for although some brands were prepared from skimmed milk, others were made from unseparated milk, and on these latter were reared thousands of the healthiest children. Dr. Willoughby admitted, however, that the excess of sugar in these condensed milks did not render them an ideal food for infants. We take it that the only advantage which can be urged in favour of preserved milks over natural milks is their cheapness, and, used as they are by the very poor only, the power of discriminating between trustworthy and untrustworthy brands not being present, the choice of a milk will be largely guided by price. Hence a great danger arises that condensed milk-fed children will be reared on skim-milk and sugar, or, rather, allowed to pine on it. No one will deny that a number of healthy, vigorous infants will thrive on foods that are far from being ideal, but it is vitally important

that medical men should concentrate their energies on obtaining, even for the poorest, a supply of animal milk—cow's, ass's, or goat's—which shall be both fresh and clean. All processes of preservation and sterilisation alter more or less profoundly the composition of or proportions of constituents in milk, and till the physiological chemistry of both child and milk are thoroughly well understood any tampering with milk is fraught with unknown dangers. We know, for instance, that fresh milk contains three important groups of ferments; we do not know how their absence prejudices a child. Condensed milk at its best is a necessary evil; at its worst it may be rank poison.

The Folly of Flogging.

THE wisdom of Solomon in these degenerate days is frequently called in question. Corporal punishment since the days of the philosopher-king has been considered a meet and right method for the inculcation of moral truths and the rectification of the sins of omission and commission which a righteous public periodically confess, but persistently adhere to. Birching in the days of our forefathers was viewed as a necessity for the discipline of the developing mind and the direction of the youthful body. But with the growth of knowledge and the coming of a measure of wisdom, corporal punishment has passed under the ban of popular opinion. The recent action of the Admiralty in forbidding at least, for a year, the brutal and degrading punishment by flogging in the Navy is a sure sign of the growth and power of an elevated tone and sound common sense which will be gladly welcomed by the medical profession. It is not long since the savage custom of flogging "round the fleet" was considered necessary for the maintenance of discipline and the protection of patriotism, but now we are in danger of passing to the other extreme and adopting effeminate and unscientific methods of correcting serious ills. Should we scratch the surface of the most highly civilised it is not difficult to lay bare the elemental savage, and we therefore cordially welcome every measure which helps to conquer the brute by evolving the man.

Pure Lymph, Violet Leaves and Insanity.

WE are frequently asked to notice the *Westminster Review*, an old-established Liberal monthly, which often contains excellent articles, but such as are more likely to be relished by the supporters of the present Government than by its opponents. It is an interesting political phenomenon that the Liberal party seeks to attract to its ranks in considerably larger proportion than the other side those extremists who war against the current opinions of doctors—a fact which is all the more curious in that of all professions it is the most liberal and catholic. In the March number of the *Westminster Review* this feature is emphasised by the appearance of three articles by different authors on such varied subjects as "Pure Lymph," the "Violet Leaf Treatment of Cancer," and the

"Progress of Insanity." The first is a survey of the origin of the various strains of lymph used for vaccinating purposes, and the various methods employed to obtain a supply free from extraneous organisms. It is written by an anti-vaccinator, and is marked by the intemperance of utterance that seems bound to cling to controversial statements on anything to do with vaccination. The second deals in so transparently simple a manner with the violet-leaves "cure" of cancer, that we could be content to pass it by without comment, if it did not contain the dangerous suggestion that early malignant disease should now be brought within its sphere of influence. With the evidence at present at our disposal of the nature of cancer and the virtue of violet leaves, it would be a terrible responsibility to postpone operation while such a method of treatment were coquetted with. Finally, the writer of the article on the "Progress of Insanity," though he seems to have a poor opinion of the Lunacy Commissioners, will be found better worth reading than the other two contributions.

Condition of Nurses' Work.

A GREAT deal of nonsense has been written during the past few weeks in Dublin, and a great deal of printers' ink wasted, in discussions regarding the conditions of nurses' work in hospitals and private houses. Public interest was roused in the matter by the unfortunate incident of a nurse's suicide in one of the city hospitals, when the coroner's jury added to their verdict an entirely irrelevant rider to the effect that the hours of duty were too long. A coroner's jury is hardly a fit body to decide as to what are suitable hours of duty for nurses, nor do we think hospital management and the nursing profession likely to gain advantage from a discussion in the halfpenny press. Mis-statements of the wildest sort have been rampant, as, for instance, that during their hours of duty nurses were forbidden on any account to sit down. On the one hand, nurses came in for fulsome adulation; on the other, for vulgar detraction. There is, of course, no doubt that nursing is a laborious occupation, and that none but strong, active women are competent to practise it. The process of weeding during the first few months of probation is, of course, hard on those who fail, and it is impossible to prevent some failing, since no matron or selection committee is infallible. We believe, however, that on the whole hospital nurses as a class are, both physically and mentally, remarkably healthy, in spite of the risks to which they are exposed. The hard work and regular hours, with wholesome diet, constitute in most cases an excellent regimen. The hours of duty by no means represent hours of labour, as anyone conversant with hospital life is aware. We wonder how many of the "Readers" "Paterfamilias," "Justitias," and so on who have recently unburdened themselves on a subject on which they know little have devoted any attention to a subject of which they ought to know

something—the conditions of domestic labour in their own homes.

Underfed Children.

It is highly creditable to the feeling of the present House of Commons that it should have passed the second reading of a Bill for the provision of meals for half-starved children not only without a division, but almost without a dissentient voice. This reform has often been championed in the MEDICAL PRESS AND CIRCULAR. No one will deny that such a measure is surrounded by difficulties, nor that its administration will be attended with dangers, but with a well-thought-out Bill these should be reduced to a minimum, and the gain to the health of the nation and to the cause of education will be of first-class importance. The Bill has now been referred to a Select Committee, and Mr. Birrell has promised to give Government facilities to allow it to pass through its first stages when it has been reported to the House, so that one may with confidence look forward to an Act being placed on the Statute Book which this session will remove one of the causes that hamper materially the development and the physique of the poor. The prime factor in the training of the mind is to arouse and fix the attention, and till that is accomplished the most highly trained teacher and the most sanitary school building will fail to achieve any educational results. It stands to reason that a child who is hungry is quite incapable of sustained mental exertion, and therefore to spend money on that child's instruction is throwing it wantonly away. A far better investment would be to translate it into food, and so do away with the education. However, as education is by law compulsory, this cannot be done, and the duty of providing food becomes a necessary corollary to enforced education. At the same time the parent who, though viciousness or extravagance, neglects to feed his own child, should be severely dealt with.

The Tramp.

THE report of the Departmental Committee on Vagrancy has just been issued as a Parliamentary paper. The Commissioners have evidently taken great pains in the collection of evidence and the preparation of their report, and in all but a few minor details they are unanimous. The tramp is such a well-recognised medium of infection, especially of small-pox infection, that he has to be seriously considered as a factor in sanitary administration, and we are glad to see that this aspect of the problem he presents has not been overlooked. Of course, the real difficulty lies in the classification of tramps, and the evidence submitted to the Committee shows that only about three per cent. consist of honest workmen in search of employment. The rest are composed of those who will never do any work for long, those that are habitually on the march and never show any desire to work, and those who through age and infirmity are too old to work.

The Committee recommend that the tramps in future shall be looked after by the police, who shall give way-tickets to all *bona fide* wayfarers in search of work, but who shall deal with the others more firmly and effectually than has been possible in the past. It is proposed that labour colonies shall be established for the benefit of the incorrigible, and that industrial and agricultural work shall be carried on in them, whilst women and children shall be received into the workhouse, the latter, when admissible, being sent to industrial schools. Special regulations are advised for the prevention of small-pox. These suggestions, if acted upon, would doubtless do much to keep a puzzling and dangerous element of the community in check.

The Professions and Pauperism.

PAUPERISM is for many a remunerative profession, but to some, unfortunately, professional life affords a path to pauperism. The hon. secretary of the Clergy Provident Union has recently published the results of an interesting research. By applying to the authorities of 700 unions and asylums he has ascertained that during the last ten years over 100 of the clergy have joined the ranks of the paupers; 42 were resident in county and borough pauper asylums, and 61 in union workhouses. Of these no less than 18 were University graduates. In the clerical and legal professions there are wide differences regarding their professional income. In the medical profession the extremes of poverty and wealth are, fortunately, seldom seen, and it is generally recognised that for every member there is what may be considered a living wage. Many, however, through infirmity, incapacity or misfortune, are brought near the poverty line, and we have no doubt that some drift into the clutches of the Poor-law. It would be well if some medical enthusiast in sociological studies would undertake a research such as the one to which we have alluded. The results would, we fear, throw strange light on certain phases of professional experience, and might perhaps indicate means whereby human wreckage might be prevented and the prestige, dignity and general well-being of the profession safeguarded.

Medical Advertising.

We must take very grave exception to the apparent action of those medical gentlemen who have allowed themselves to be drawn into contributing not alone their opinions, but even their photographs, to the pages of a monthly contemporary. In the *Strand Magazine* for March appears an article, entitled "How to be Healthy at all Ages. A Symposium of Eminent Doctors." The article commences with the statement (in which is embodied a series of questions) that "a number of medical gentlemen of high-standing were approached and asked if they would accept a commission to answer the questions." What these are our readers can ascertain elsewhere. They are too long to be reproduced, and in them-

selves are unobjectionable. Some nine gentlemen were found to consent to this arrangement, and the remainder of the article is taken up by their answers—and their photographs. Of those thus distinguished the addresses range from Harley Street, London, to Roxburghshire in Scotland. Irishmen, we are glad to say, are conspicuous by their absence. The professional attainments of these gentlemen and their contributions to medical literature are apparently as varied as their addresses. The qualifications and appointments of one occupy a third of a column of the Medical Directory, those of another occupy six lines only. One contributed to medical literature for the last time in 1876, another for the first time in 1903. Four apparently possess the same address they possessed in 1903, and four have since changed. One was qualified in 1859, another in 1901. According to the magazine referred to, they all possess a high range of experience, and, in our humble opinion, if they have acted, as our contemporary leads us to suppose, they have done so in direct contravention of the rules of medical etiquette. Should any of the contributors feel aggrieved by this statement we shall be most happy to give their explanation every publicity. If they have been unwittingly drawn by enterprising journalists into the false position they occupy, they should see to it that the latter are made to publicly apologise.

PERSONAL.

HIS MAJESTY THE KING, being present in Paris during the taking of the quinquennial census, made his return from the British Embassy. It is interesting to recall the fact that at the last census both the late Queen Victoria and the King, then Prince of Wales, were in France.

THE London Hospital will soon possess a statue of its President, Her Majesty the Queen, who has graciously consented to give sittings for the purpose to Mr. George Wade.

A GLASGOW University club has been started in Manchester under the presidency of Dr. Alexander Welsh, of Whitworth, who graduated in the year 1864.

DR. KYNASTON COUCH was last week entertained by a large circle of friends on the occasion of his departure to Western Australia. Dr. Couch has been connected with hospital work in Swansea for the last eighteen years.

DR. W. K. HUNTER has been elected to the vacant post of physician to the Glasgow Royal Infirmary, and Dr. H. Rutherford and Dr. P. Paterson to the two vacant surgeoncies.

DR. JOHN CAMPBELL, Belfast, President of the Royal University Graduates' Association has decided to offer himself as a candidate for the Senatorship of the Royal University of Ireland. In his address he states that he is in favour of extern examiners, an interesting statement in view of the fact that the Senate for some so far unexplained reason has just abolished them.

THAT most flourishing energetic body, the Irish Medical Schools' and Graduates' Association will hold their next dinner at the Hotel Cecil, Strand, on Saturday March 17th, at 7 p.m. Details may be obtained of the Hon. Sec., E. Canny Ryall, Esq., 85, Harley Street, London, W.

A CLINICAL LECTURE ON THE ROUTINE EXAMINATION OF THE FÆCES IN GENERAL PRACTICE, AND WHAT WE LEARN FROM IT.

By GEORGE HERSHELL, M.D. Lond.,
Senior Physician to the Queen's Jubilee Hospital.

ANYONE who peruses a modern text book of medicine cannot fail to be struck by the omission of almost any mention of the clinical examination of the fæces. In any case when given the methods described necessitate the use of a properly-equipped laboratory and are not applicable to the exigencies of ordinary practice. And this omission is the more inexcusable from the fact that in the last two or three years important work has been done in this field and methods elaborated, which for all practical purposes place the examination of the fæces on the same level as the examination of the stomach contents, with which we all are, or should be, familiar.

It is the object of the present lecture to give a short description of such of these methods as are easy of execution, within the compass of any medical man even although unversed in laboratory methods, and from which results can be obtained of sufficient value to repay those who will take the trouble to perform them. The tests in question are few in number, and will be discussed seriatim.

(A.)—ESTIMATION OF THE TIME OCCUPIED BY THE FOOD IN PASSING THROUGH THE ALIMENTARY CANAL.

The time taken by the food in passing through the gastro-intestinal tract is a matter of great importance, and as yet has received singularly scanty attention from practising physicians. The first and most important fact to grasp in commencing the study of the subject is, that delay in the passage of the food may occur, not only in cases of obvious constipation, but may be present in patients who are passing a daily stool, and whose functions are considered to be regular, not only by themselves, but also by their medical attendant. In such cases, what we may justly term a *latent constipation*, may be the real cause of obscure conditions of ill-health to which no obvious cause can be assigned. In these cases there is, in all probability, a slight continued auto-toxis from the intestines. With respect to intestinal peristalsis we may conveniently divide all patients into the following groups:—

(a) Those in whom the food traverses the whole of the alimentary canal in the normal time. In these cases there is a sufficient stool every day. The period occupied by the food in passing from mouth to anus will vary somewhat according to the diet on which the patient is living. Thus, with a diet consisting entirely of lean meat the time is twenty hours (Strauss), with a purely milk diet thirty-six to forty-eight hours (Maurel), and with an ordinary mixed diet as we should naturally expect, about twenty-four hours (Kozickowski).

(b) Cases in which the food traverses the small intestines and colon as far as the commencement of the sigmoid in the normal time, but afterwards delay occurs. In some few of these cases the condition must be considered a normal one. In the cases under consideration the natural capacity of the sigmoid is so great as to allow the debris from the meals of two days to accumulate before it is filled sufficiently to set up the reflexes leading to defæcation. But when this takes place the sigmoid is completely emptied and we must consider these persons as normal, but with increased sigmoid capacity. But in other cases there is a condition of atony which interferes with the complete emptying of the lower bowel, and the stools are either deficient in quantity or in severe cases retained in the bowel until extraneous help be given either by injections or laxatives.

(c) Cases in which the whole delay is in the upper part of the intestine and the sigmoid, and the rectal reflexes are normal. In these cases there is not of necessity any constipation as the patient understands it, as there may be, and usually is, movement of the bowels every day. The effect of the delay of material in the intestine is to allow a constant slight degree of auto-intoxication which inaugurates and perpetuates a chronic condition of ill-health. In these cases the fæcal retention continues until a point of tolerance is reached, when the patient will experience a "bilious attack" or will take a dose of medicine and empty the bowels. I am convinced that in the majority of patients who suffer from periodical attacks of this nature the real source of the trouble is an unsuspected condition of intestinal atony leading to chronic slight fæcal retention. It is quite possible for patients with this condition of atony to suffer from looseness of the bowels or diarrhoea. This may happen in cases of catarrh of the lower bowel.

(d) Cases in which there is atony of the whole of the intestines. This condition is frequently met with in chronic colitis and is usually accompanied by constipation.

(e) Cases in which intestinal peristalsis is increased. In these cases we usually find diarrhoea more or less marked. We are thus able to see that things are not always as they seem, and that patients, with apparently regular movements of the bowels and even with a certain amount of looseness may really be suffering from intestinal atony, with delay of the food in the intestines, and to appreciate the clinical advantage it would be to us in our work if we had some simple method of measuring the actual time taken by the food in its passage along the alimentary canal. Fortunately we have such a method at the disposal of anyone who will take the trouble to use it, which is simple in the extreme. We have merely to administer to the patient with one of his meals some coloured substance, which shall be harmless, unacted on by digestion, and unalterable in colour, and note the time when it appears in the stools.

Technique of the Test.—We give the patient at breakfast one or two Belloc's pastilles of vegetable charcoal. Normally the stool next morning should be blackened. If the charcoal does not appear in the stool until the next day or the day after that there is abnormal delay. In cases of constipation the rectum may be emptied by means of a small enema of cold water:

Clinical Indications derived from the Test.—The estimation of the time actually occupied by the food in its passage may be useful under the following conditions:—

1. In cases of neurasthenia, so-called lithæmia, indigestion, and conditions of chronic ill-health generally, in order to ascertain whether these morbid conditions may not be due to delayed passage of food and consequent auto-intoxication.

2. In cases of obvious constipation to obtain a measure of the actual degree of the delay.

3. In cases of diarrhoea to inform us as to which part of the intestinal tract is involved. Thus—(a) If the indicating colour does not appear in the fæces until nearly the proper time we are able to learn that the morbid process has its seat in all probability in the lower parts of the colon, and that the peristalsis of the small intestine is not increased. (b) If the indicator appears in five or six hours, we are definitely able to state that the seat of mischief is in the small intestines. This finding will be confirmed by the test for bilirubin

to be presently described. Of course in cases of diarrhoea we shall examine every stool.

4. As an indicator to tell us when a test meal has reached the rectum.

(B.)—THE EXAMINATION OF THE STOOLS FOR "OCCULT" BLOOD.

One can have no hesitation in saying that, from the point of view of the gastro-enterologist, the introduction of this test into practice is one of the real advances in clinical medicine which have been made during the last two years. Not only is it of definite value, but its technique is so simple as to place it among the processes which are applicable to every-day practice. By occult blood is meant blood in such small quantity as not to be visible macroscopically. Such blood in the stools cannot be demonstrated by the microscope on account of changes it has undergone during its passage along the alimentary canal, and requires a chemical test for its recognition. For this valuable test we are indebted in the first instance to Boas, subsequently to Hartmann and others.

Technique of the Test for Occult Blood.—It is obvious that the first thing to do is to put the patient on a diet from which hæmoglobin-containing substances are excluded, and, unless the time occupied by the food in passing through the alimentary canal has already been estimated, to give a dose of charcoal as an indicator. We shall in this manner be enabled to judge when the contents of the alimentary canal at the moment of commencing the hæmoglobin-free diet have left the body and our test diet commences to appear in the stools. Then, and not until then, can we apply the test with any expectation of reliable results. The test diet must be free from meat and fish, and should consist of milk, junket, eggs, custard, bread, oatmeal, rice, tapioca, macaroni, cauliflower, white beans, onions, butter, and cheese. With these a sufficiently appetising menu can be constructed for the patient to tolerate for a week or two. Such, for instance, as the following should not be any very great hardship for a short time—

Breakfast.—Porridge and cream; eggs, bread and butter; tea, coffee, or cocoa.

Lunch.—Milk, soup, white fish, mashed potatoes, macaroni with milk, or *au gratin*.

Dinner.—Soup made with vegetable stock, white fish, a savoury dish of eggs, no meat stock, or Liebig's extract being used in the gravy, but the flavour obtained with onions, celery, Maggi's essence, or curry powder. Potatoes, white fish, a vegetable course such as haricot or salad, junket or custard, apple fritters, cheese, butter, biscuits and celery, and as dessert, nuts or almonds.

Of course, it is needless to say that such a diet as the above would not be given to a patient with obvious disease of the stomach, and is quoted mainly as an example of an ordinary diet modified in such a manner as to give no reaction with the test. In the majority of cases where ulcer or cancer is suspected the patient will be already upon liquid diet, and nothing more will be required than to make sure that all beef tea, meat broths, and stock are excluded from the dietary.

The apparatus required consists of several small porcelain dishes, a glass mortar, a glass rod, and a test tube graduated at 10 cc., 13 cc., and 18 cc. We also require the following re-agents—methylated ether, acetic acid, freshly made tincture of gualacum, ozonised oil of turpentine, aloin in powder, and a small quantity of 70 per cent. spirit of wine.

A small piece of faecal matter is rubbed up in the mortar with a few cc. of water, poured into the graduated test tube and further water added to the 10 cc. mark. Place the thumb over the top of the tube and give it a good shaking. Now pour in ether to the 18 cc. mark, shake again and place in the rack to settle. Whilst you are waiting for this, occupy your time by preparing an alcoholic solution of aloin in the following manner: Take as much dry aloin as will lie on the point of a

pen-knife and place in a dry test tube with about 5 cc. of the alcohol, shake vigorously and place aside in the rack. By this time the first tube will be ready, and it will be found that the ether has risen to the top, carrying with it the fat contained in the faeces. This has to be removed and the easiest way to do this is to suck it up with one of the pipettes or medicine droppers by compressing and allowing the rubber bulb to expand. Remove carefully all the fat-containing ether from the surface of the fluid which should now stand again at the 10 cc. mark in the tube. Pour in acetic acid to the 13 cc. mark and shake for a couple of minutes. Now add ether to the 18 cc. mark and shake again. Now place in the rack for a short time. The acetic ether extract will now rise to the surface and will contain the colouring matter of any blood which may be present. With another of the pipettes suck up one or two cc. of this and place in one of the porcelain dishes. Repeat the process and place the same quantity in a second dish. To the contents of the first dish add 5 minims of the tincture of gualacum and stir up with a glass rod. Now add drop by drop 5 to 10 minims of the turpentine. If any blood be present the mixture will assume an intense blue colour. To the material in the second dish add 10 minims of the turpentine and stir up well. Then add a few minims of the alcoholic solution of aloin and stir again. A bright red, turning to a cherry red on standing, will denote the presence of blood. It is as well to make use of both the gualacum and of the aloin in every case as thereby we eliminate any source of fallacy due to the dark colour of the acetic extract or to the presence of fat or fatty acids.

This method of performing the test I venture to think removes the chief difficulty experienced by the beginner—that of removing the ether extract from the fluid underneath. This is difficult to pour off in the small quantity with which we are working, and the separator in use in laboratories is naturally not available, and, moreover, cannot be conveniently applied to the small quantities which I advocate to be used. The advantages of working with small quantities from an æsthetic point of view is of course obvious.

Clinical Indications derived from the Test.—The presence of occult blood in the stools will point to slight bleeding at some point of the gastro-intestinal tract, (hæmorrhage from gums, nose, and throat being, of course, excluded), and will have precisely the same significance as macroscopic blood under the same conditions. In medical practice the knowledge that such slight bleeding is taking place is useful to us in the following conditions:—(a) In chronic disorders of digestion from a diagnostic point of view. If occult blood be found in the stools there is, in all probability, either cancer or ulcer of the stomach or duodenum, the conditions which may also be attended with slight bleeding under certain circumstances having first been carefully excluded. These are, purpura of the gastro-intestinal tract, hæmophilia, hæmorrhoids, fissure and fistula of the rectum, and cirrhosis of the liver. Of these the last is the most important, from a diagnostic point of view, as it is the most likely to lead to errors in practice. It has been reported by some observers that occult blood has been found in spastic and non-malignant stenosis of the pylorus, but it is more than likely that ulceration was really present in these cases. The more experience I gain the stronger grows my conviction that there is some ulceration present in practically all cases of reflex spastic contraction of the pylorus. These conditions then having been excluded, if we find the occult blood on several successive days it is almost certain that we have to do with malignant disease. If, on the other hand, there are days on which it cannot be found, there is a strong probability that ulcer is present. The fact has now been definitely determined that in cancer the blood is almost always invariably present, but in ulcers only intermittently. It is, therefore, our duty to place the patient on an appropriate test diet and examine the stools for occult blood in every case of chronic dyspeptic trouble which is rebellious to treatment, in which there is emaciation

or in which the patient is losing ground—however slowly.

In such a case we would first of all make sure that the conditions which might lead to error are absent, we then put the patient to bed and commence the test diet by giving a dose of vegetable charcoal with the first meal. As soon as the stools become black we may commence our tests for occult blood. We continue the tests for a week, during which the patient remains in bed for many and weighty reasons. As the result of our tests—

1. We may find blood on each occasion. There is almost certainly cancer.
2. We may find blood on one or more occasions during the week, but not every day. The case is probably ulcer.
3. We find no blood. In this case we wait a couple of weeks and then devote another week to testing. If the result be still negative we can pronounce the patient to be free from cancer and ulcer.

The comparatively long period taken up by the test should not carry any weight either with ourselves or the patients when we take into consideration the importance of the issues involved, and the fact that upon our finding will depend whether we condemn the patient to a long treatment in bed or to a serious operation.

(b) During the treatment of a gastric ulcer we may derive invaluable information. This has been well detailed by Dr. J. Dutton Steele* in a paper read before the Section in General Medicine of the College of Physicians of Philadelphia, Nov. 13th, 1905. He states that in his opinion the test for occult blood will be of prognostic and therapeutic value in the course of gastric ulcer under the following circumstances:—First, to determine the length of the various periods of the medical treatment of ulcer. Second, to detect a tendency to bleeding during the course of gastric ulcer, and by appropriate medical and surgical measures to anticipate and prevent serious hæmorrhage. Third, to determine when the medical treatment may be considered to have failed and surgical treatment is indicated. Fourth, perhaps the test may prove useful under certain circumstances in detecting the development of a cancer upon the floor of an ulcer.

(c) As a means of anticipating the occurrence of hæmorrhage in typhoid fever. As a rule serious hæmorrhage from the bowels in this affection will be preceded by occult blood for three or four days. We should, therefore, examine the stools two or three times a week during the dangerous period as a matter of routine.

(C.)—THE SUBLIMATE TEST FOR THE CONDITION OF THE BILE PIGMENT.

In a normal stool the bilirubin of the bile has been reduced to hydrobilirubin. In cases in which from any cause there is increased peristalsis in the small intestine the semi-digested food is hurried on before there has been sufficient time for this change to take place. We are able therefore, by determining the presence of bilirubin in the reduced or unreduced form respectively, to know definitely whether the peristalsis in the upper bowel is or is not increased, and consequently in cases of diarrhoea to give a definite opinion as to which part of the intestinal tract is involved in the morbid process.

Technique of the Test.—If the stools are liquid they can be used undiluted. If solid or semi-solid, a small portion is to be rubbed up with distilled water in the glass mortar. About 5 cc. of the liquid stools or of the stool solution are to be placed in a test tube and to them are added an equal quantity of a 25 per cent, watery solution of corrosive sublimate. If the stool is normal as regards the bile acids, a pinkish colour will develop showing the presence of hydrobilirubin. A green colour will show the presence of unreduced bilirubin.

Significance of the Test.—In a case of chronic diarrhoea the normal pink reaction would point to the fact that we had a colitis to deal with, and that the small intestine was not involved. Per contra—a green colouration

would point to the fact that the small intestine was involved.

(D.)—THE FERMENTATION TEST.

This test is very easy to carry out and is of great value in cases of presumed intestinal indigestion, as it enables us to determine not only the presence of abnormal fermentation in the intestine, but also whether the starchy or the albuminous ingredients of the food are the subject of the morbid process.

Technique of the Test.—Mix a small portion of the fæces with distilled water in the mortar until it is a little thinner than cream. With the mixture fill a Doremus' or Down's ureameter. Stand this in a warm place for twenty-four hours. Any fermentation which takes place will be accompanied by the evolution of gas, which will displace downwards the contents of the upright tube. The volume of gas may then be read off on the scale exactly in the same manner as the volume of nitrogen produced in the course of the familiar urea test. In the first place we must distinctly understand that fermentation of any kind is abnormal. If the gas evolved in twenty-four hours fills one-third of the tube there is certainly some pathological condition present, as there must be considerable fermentation of the intestinal contents. To find out whether the fermentation is amylaceous or albuminous we compare the total acidity before and after fermentation has taken place. If the total acidity is increased, the fermentation is of an amylaceous nature, if, on the contrary, the acidity is diminished, the fermentation is albumin fermentation. In the latter case the solution of fæces has become alkaline and foul smelling, and the condition of matters is often sufficiently obvious. The method of estimating the total acidity is the usual one of titration with a decinormal solution of sodium hydrate with phenolphthalein as an indicator. For the benefit of those of my readers who may not be familiar with the modern laboratory methods I may be pardoned if I briefly give directions for estimating total acidity. The first thing to do is to ascertain whether the fæces are acid or alkali. This is best accomplished by dropping a little of the solution of fæces which we have made into a little weak watery solution of litmus in a porcelain dish. If we find it acid we may proceed with the test for total acidity. We measure out ten cc. of the solution of fæces and add to it a few drops of a one per cent. alcoholic solution of phenolphthalein and stir up well with a glass rod. You now allow to run into this, drop by drop, a decinormal solution of sodium hydrate and note the moment when a red colouration is produced which does not disappear on stirring. The number of cc. used to produce this reaction multiplied by ten, is conventionally taken to represent the degree of acidity. If, however, we find the solution of fæces alkaline or neutral, we titrate in the same manner with a decinormal solution of hydrochloric acid until the fæces will give a reaction with litmus. The amount of hydrochloric acid added will represent the acid deficit in terms of hydrochloric acid. If any acid is produced during the process of fermentation the acid deficit will, of course, be correspondingly lessened.

Clinical Indications derived from the Test.—This test is especially valuable in deciding upon the dietetic treatment of cases of intestinal indigestion. By knowing for certain the kind of indigestion, we are enabled to reduce, or cut off entirely for a time, the food stuff which the test shows us undergoes abnormal changes, and thus to arrest the multiplication of the offending germs by depriving them of their accustomed pabulum. We are thus enabled to gain time to adopt the measures which experience has shown us are adapted to restore functional health to the organs and tissues involved.

(E.)—THE EXAMINATION OF THE FÆCES FOR UNDIGESTED CONNECTIVE TISSUE AND MEAT FIBRES.

Technique of the Examination.—This is merely a simple microscopic examination.

Clinical Indications.—The presence of undigested connective tissue fibres in any quantity will point to a

* Abstracted in the *New York Medical Journal*, Jan. 20th, 1906.

disturbance of the gastric digestion. If undigested meat fibres are found the indigestion is situated in the small intestine. In the latter event the precise condition present is unfortunately in the present state of our knowledge not revealed, and we are unable to say whether the trouble is caused by:—(a) a pancreatic secretion deficient in quantity or defective in quality, (b) deficiency in the enterokinase, the ferment which renders the pancreatic juice functionally active; (c) the onward movement of the food before efficient digestion has had time to take place, the result probably of increased peristalsis.

The knowledge obtained by this test cannot fail to be of considerable use to us in the treatment of chronic affections of the gastro-intestinal tract, especially as regards the appropriate diet to be given. For instance, in cases of chronic diarrhoea it will not infrequently be found that there is an inability to digest meat fibre, whilst the functions of the stomach are approximately normal. In these cases a restriction of the diet to starches and fat will usually be promptly followed by the cessation of the diarrhoea and a restoration of the patient to health. Conversely, in many cases of intestinal flatulence, it will be found that whilst both the meat and connective tissue are well digested the test already described shows that there is abnormal fermentation of starch in the intestine. In these cases a largely proteid diet, together with the administration of taka-diastase, has been followed by the happiest results.

It is an important point to bear in mind that, for a couple of days before making the examination for undigested meat fibres or for connective tissue in the stools, the patient should be placed upon a diet containing approximately 100 grammes of meat in the twenty-four hours, with a proportional amount of other articles of food to constitute an ordinary mixed diet. This quantity of meat is selected because it represents the amount which should be easily dealt with by the normal digestive apparatus, whilst at the same time it is a very fair test for a slightly lowered digestive capacity. The actual test diet recommended by Dr. Dutton Steele, to whose valuable work allusion has already been made, is as follows:—

Breakfast.—Two eggs, two pieces of toast and butter, two glasses of milk, and a plateful of oatmeal porridge with milk and sugar.

Dinner.—A quarter of a pound of underdone steak, two pieces of toast and butter. One and a half tumblers of milk.

Supper.—Two glasses of milk, one or two eggs, two pieces of toast and butter.

(E.)—THE DETECTION OF ABNORMAL MUCUS IN THE STOOLS.

We will omit the consideration of the large quantities of mucus which are characteristic of mucous colitis and the mucus of little or no significance which is so often observed coating the surface of hard, faecal lumps, and direct our attention to that which is intimately mixed with the stools. This alone is of any considerable importance from our present standpoint.

Technique for the Demonstration of Mucus.—Rub up a piece of the faeces with distilled water and pour the solution obtained on to a flat glass dish. The dishes used in photography answer admirably, and only cost a few pence. Hold the dish over a piece of black velvet, paper, or card, so as to form a background, and allow a good light to fall upon the dish from the side. The mucus can be recognised as small transparent flakes, often stained yellow by bile.

Clinical Indications.—The important point to bear in mind is, that although mucus is always present in normal stools it can only be demonstrated by chemical tests. It may be enunciated as an axiom of universal application, that when one is able to find it macroscopically it is always pathological. In fact, it is a general rule that the presence of mucus in the stools in the form described indicates the presence of inflammation in some portion of the mucous membrane

lining the gastro-intestinal tract, and may be considered an infallible sign of its presence.

These, then, are the few simple tests which I feel confident may be usefully employed as diagnostic aids even in the hurry of daily practice. They are easy of performance, require practically no special apparatus, and take up no more time than the routine examination of urines to which we are all so accustomed.

In the limited space at my disposal it has been, of course, obviously impossible to deal at all exhaustively with a subject covering so considerable a field; for instance, the significance of fat in the stools has not even been touched upon. It is, however, hoped that sufficient details have been given to enable the several tests described to be performed without difficulty, and that the deductions which may be legitimately drawn from the results obtained have been set forth with sufficient explicitness to render them as serviceable to my readers as they have proved to myself.

If no more has been accomplished, I venture to hope that I have done a little towards awakening an interest in methods which must infallibly enhance our power of dealing effectively with the obscure clinical problems which continually offer themselves for solution.

NOTE.—A *Clinical Lecture by a well-known teacher appears in each number of the journal. The lecture in next week's will be by Mr. A. B. Mitchell, F.R.C.S.I., Surgeon to the Royal Victoria Hospital, Belfast, on "Acquired Flat Foot."*

ORIGINAL PAPERS.

ACUTE NEURITIS OF BRACHIAL PLEXUS.

A WELL-KNOWN hospital surgeon has sent to us the following interesting notes upon his own case:—In early October, whilst staying in an hotel in London, I felt what I considered to be a little rheumatism about the left shoulder. After three days, when about to join a shooting party, I found I was not able to hold the gun, and on that day I went to bed in the afternoon, suffering somewhat considerable pain. On the following day (Sunday) I went to take my usual morning warm bath, but on lifting the left arm experienced an excruciating pain like tearing the muscles in the upper arm, and was forced to return to bed. The pain now became little short of intolerable, and from its position and character, it was clear that the nerves forming the brachial plexus were affected almost up to the cord, for the pain extended along the intercostal nerves and the side of the chest. The pain was deep-seated and aching in character, along the inside of upper arm, extending along the ulnar into the little finger over the skin of the fore-arm; it was lancinating like thousands of punctures; at the back of the shoulder it was boring, like a bradawl being worked through the centre of the scapula. Any attempt to move the arm was accompanied by a terrible tearing pain along the inner upper arm. Some local medical friends came to see me and with their opinion, we concluded that it was neuritis, probably of a gouty character, as I had already had an attack of gout in the great toe, and my father and grandfather had been what are termed martyrs to the gout. The treatment was colchicum, bicarbonate of potash, and tr. belladonna; also daily purgation, and for the relief of pain occasional doses of phenacetin and local application of laudanum applied on lint within a sheet of cotton wool. When the pain was sickeningly severe I was advised to have a morphia injection, but I made objection as I was not aware of the state of the kidneys, and did not wish to investigate whether they were sound or not. The arm was kept perfectly still on a pillow, wrapped in the cotton wool, and any accidental movement such as turning the body brought on the tearing pain of the muscles. From time to time during the

day the pain ceased so long as no movement was made, even for some hours at a time, and after remaining in bed for a fortnight I attempted to get up and remained sitting in a chair with the arm supported in a sling for some four hours, but at the end of that time the aching was again excessively severe and I had to return to bed. It now became necessary to have a hospital nurse. The intolerable pain in all its varieties was as severe as ever. With the nurse, hot fomentations were applied, Salicin and also guaiacum were taken in addition to the other remedies, aconite liniment was applied, but it was not until the end of six weeks that any great diminution of the pain took place. Now I was able to get up for three or four hours a day and to sit in an easy chair with the arm slung.

I was brought to London with the object of taking advantage of Turkish baths, but the first bath increased all the symptoms, and the second bath very plainly showed that it was a wrong treatment; it was clear that the movements necessitated in the course of taking a bath, and more especially during the process of the massage, were injurious to the inflamed nerves, and I was quite unable to continue them. As I was now again becoming daily worse I sent for a London physician, a former colleague of my own, who ordered me aspirine and the electric light bath with warm douche, and also a local application of menthol, chloroform, &c. Under these my pains subsided rapidly. I continued the treatment for three weeks, taking a bath every other day, and at the end of that time I was able to leave England on December 15th, for South Spain, but still being compelled to retain the arm in a sling. If the arm were allowed to hang, aching commenced in a few minutes, and it was not for another fortnight that I could dispense with the sling.

The attack extended over a period of thirteen weeks. The remedies did not demonstrate any immediately successful effect. The local applications of aconite, menthol, &c., in my opinion, increased nerve irritation and induced pain, but laudanum subdued nerve irritation and relieved pain. All the synthetical remedies — phenacetin, anti-pyrine, antikamnia — certainly subdued nerve irritability, relieved pain and permitted or induced sleep. The objection to the use of subcutaneous injection of morphia resulted in the loss of a most valuable remedy which certainly would have relieved the pain at a time when its severity was scarcely to be borne, and might have shortened the disease. Hot fomentations were unmistakably beneficial. The Turkish bath treatment is clearly contraindicated, for the inflamed nerves cannot bear pressure, manipulation, or even movement more than could an acutely inflamed periosteum. The electric light bath and gentle hot douche were most grateful and soothing, and unmistakably an effective remedy, but as more than five weeks of the disease were spent in a condition in which I was unable to change the position of the body without bringing on the unbearable pain, it would have been difficult or impossible to take advantage of it before some of the severity of the disease had been subdued. The question may be asked, was the disease functional such as neuralgia may be conceived to be, or was there actual change in the nerves? I made out a distinct enlargement or infiltration in the region of the plexus, but I need scarcely add that I objected to much manual examination, for pressure on the plexus or the shoulder or the scapula or the axilla or in that region where the anterior branches of the intercostal nerves penetrate immediately gave rise to the acute pains in all the other regions as by reflexion, but a fact worth being recorded is that pressure could be applied above the clavicle where the upper nerves forming the plexus could be reached, and yet no pain was thereby produced. So far as permanent damage to the nerves is concerned I may say that at the present time, five months from the commencement of the attack, the strength of the limb is unaffected, but small or precise movements of the little finger are awkward, less strong and precise, and, so far as sensation is concerned, lying upon the limb at night or

exposure to cold, such as on damp or extra cold days, produces aching results.

Finally, I may say that as a surgeon I did not meet with idiopathic neuritis of an acute form, and scarcely believed in its existence, but the last five months have given me a very thorough insight into the disease.

TWELVE CASES OF PROFUSE DESQUAMATION IN TYPHOID FEVER.

By JOSEPH BEARD, F.R.C.S. EDIN.

Resident Medical Superintendent, Infectious Diseases Hospital, Borough of Bootle.

In a contemporary journal in the early part of the year 1904 there appeared amongst the annotations a reference to desquamation of the skin in typhoid fever.

The note after referring to the great French clinician, Louis, as having long ago described the condition, further said that desquamation in typhoid fever is either unnoticed or little more than mentioned by most writers. On exploring modern text-books for information I am struck with the scanty and apparently unimportant short references to the condition, and the few remarks with which the writers content themselves do not leave any one the wiser with regard to the pathology of the process. It is true, as Dreschfield in "Allbutt's System of Medicine" says, "that desquamation of fine branny scales is often observed towards the end of the fever, or during convalescence," and with those remarks dismisses the subject. Osler, "Principles and Practice of Medicine," fourth edition, says that "a branny desquamation is not rare in children, and occasionally peels off in large flakes."

Notice is further paid to an article which appeared in the *American Journal of Medical Sciences* for January, 1904, which contained an important paper by Dr. David Riesman, who reports two cases and reviews the literature upon the subject.

I will quote briefly the facts of one of the cases as recorded by him.

"A male adult admitted into hospital January 23rd, 1902, with typhoid fever eruption. The attack was severe with widespread rash. The spots appearing on the face, arms, thighs, and legs. The temperature became normal on February 12th, probably the end of the fourth week. On March 3rd the patient had a severe chill, after which the temperature rose to 106°F., with pain in right side, followed by pleuritic effusion. Aspiration was performed and early in April the patient left hospital in fair health." He says that "desquamation occurred during convalescence (date not given), it was widespread and some of the scales were a quarter of an inch long. The chest and abdomen most marked, and but little less marked on the limbs, distinct on the face and neck. Scalp, shoulders, palms, and soles not affected. Riesman concludes that three forms of desquamation in typhoid fever may be distinguished.

I. That confined to the roseolar spots; sometimes the spots have a tiny vesicle on their summit, which forms a thin scale.

II. That appearing as a sequel to sudamina. This form is confined to the area of the sudaminal eruption, though Louis states that the intervening skin may be peeled off. The desquamation is usually furfuraceous but is sometimes scaly; it occurs upon the trunk and proximal parts of the limbs, never upon the distal parts of the limbs or upon the face.

III. Desquamation as illustrated by the case briefly recorded above, where there may be almost universal desquamation, furfuraceous or lamellar, and which he says may be due to "trophic changes analogous to shedding of the hair."

It affects the trunk and proximal parts of the limbs, rarely the distal parts of the limbs and face. Usually the extent and intensity of the desquamation are related to the severity of the fever.

During the past eighteen months I have had under my care eleven cases of typhoid fever in which well-

marked desquamation has taken place, and I have also seen one other case in the practice of a friend, the notes on which I also add to those of my own cases.

This latter case was a female, *æt.* 20, whom I saw with a medical friend in North Wales. When first seen she had been in bed for four days, her temperature was 102.4°F., expression easy, tongue coated with thin white fur, with sides and tip reddened, no diarrhoea, abdominal signs nil, no spots observed, Respiration 20 per minute. Pulse 102 per minute, regular, full and soft. She remained very much in this condition for sixteen days, when general improvement set in. The temperature for a few days was remittent, but quickly fell to normal. On the second day of the normal temperature she complained of tenderness of the toes and skin of the feet over the plantar aspect of the metatarsophalangeal joints of both feet (a condition which occurs in some cases of typhoid fever), and it was also noticed that the skin of the trunk was very rough. In a few days she had profuse desquamation, the face, scalp, palms and soles escaping. The skin of the trunk desquamated in large flakes a quarter of an inch long, the shoulders, arms, and forearms, being smaller and more furfuraceous in appearance.

The notes of my own eleven cases are briefly as follows:—

Case I.—E. W., male, *æt.* 12. Admitted ninth day of disease, abdomen distended, bowels loose, averaging two motions per day during first week, after which constipated, spleen easily felt, spots, about seven observed, Widal's reaction positive, temperature on admission 104°F., afterwards regularly remittent and intermittent and until thirty-seventh day when it became normal, after first day temperature was never over 103°F. Desquamation was first noticed on the twenty-seventh day of disease and continued for thirty nine days. The desquamation was universal. The flakes from the lower part of the back and abdomen being almost half an inch in length. The general desquamation was furfuraceous.

Case II.—G. A., male, *æt.* 19, admitted tenth day of disease. Temperature on admission 102.6°F., reached as high as 104°F. on the fifth day after admission, after which irregular remissions took place, intermitting on the eighteenth, twentieth, and twenty-fourth days after admission, reached normal on the thirtieth day after admission—*i.e.*, fortieth day of disease. The attack was smart; he was drowsy on admission, rambling and somewhat incoherent in speech; spleen easily felt, spots very profuse, occurring in hundreds on the trunk, both front and back, and also upon the arms and thighs. Bowels loose first two motions, but not afterwards during the whole time in hospital. The skin on the eighteenth day of disease was observed to be very dry, and on the twenty-first day began to desquamate freely, and in large flakes from the trunk and legs, small flakes from the shoulders and arms, but scarcely any from the forearms, desquamation was completed on the thirty-third day of disease. (Widal's reaction positive.)

Case III.—E. McC., male, *æt.* 11, admitted fifth day of disease, had history of epistaxis and diarrhoea. Temperature on admission 101°F., reached 103°F. third day after admission. Fifth day after admission became irregularly remittent and on seventh day intermittent, reached normal on the twenty-fourth day after admission. Condition on admission restless but sensible, abdomen flat with tenderness in right iliac region. No spots observed. No diarrhoea, spleen easily felt. (Widal's reaction positive.) Desquamation commenced on the nineteenth day after admission, first the trunk then the face, arms, and legs, in large thick flakes, and was completed on the thirty-fifth day after admission.

Case IV.—M. H., female, *æt.* 13, admitted about fifteenth day of disease. Temperature on admission, 103.6°F., the highest point reached, from the first remittent until the twenty-second day, when it became intermittent, reaching normal on the thirty-first day of disease. Abdomen on admission somewhat full, spleen easily felt, no diarrhoea, three or four spots only

observed. Desquamation (no note of day of commencement) of a furfuraceous character from the whole of the trunk, the arms and legs. (Widal's reaction positive.)

Case V.—G. A., male, *æt.* 8. Admitted eighteenth day of disease. Temperature on admission 101.6°F., fell to normal in forty-eight hours, remained slightly below normal for three days, then by a gradual ascent rose to 101.4°F., falling to normal again in forty-eight hours. Thirtieth day of disease reached 100.6°F., fell in thirty-six hours to normal. (Widal's reaction positive.) Thirty-eighth day temperature rose to 100°F. and was irregularly remittent and intermittent, varying from 98°F. to 101.4°F., for ten days, when it became normal and remained so. (Widal's reaction positive.) On admission the child was apparently very ill. Abdomen flat, a few spots, about four in number, on the abdomen, spleen easily felt, no diarrhoea. Pulse 100 per minute, irregular and dicrotic. Desquamation (no date of commencement), of furfuraceous character small but plentiful from the whole of the trunk; shoulders, arms, &c., did not desquamate.

Case VI.—F. D., female, *æt.* 16, admitted ninth day of disease. Temperature 104°F. which was the highest point reached. Temperature became remittent on the twentieth day, and fell to normal on the twenty-fifth day. On the following day, there was slight progressive pyrexia which reached 103.6°F., on the thirty-sixth day, and until the fifty-eighth day, the temperature was irregularly remittent and intermittent, varying from 104°F. (highest) to 96.6°F. (lowest). She was markedly ill on admission, abdomen distended, diarrhoea (first day only), spleen easily felt, tongue very dirty; pulse 120, markedly dicrotic; bases of lungs congested, no spots. (Widal's reaction positive.) Desquamation commenced on the thirty-first day of disease and continued until fourteen days before her discharge. The whole of the body was involved in the desquamating process, which took the form of large thick flakes, some of them from the trunk were half an inch in length, whilst flakes from the palms and soles came away in pieces varying in size, but some being as large as a penny piece. The head, face, shoulders, arms, and legs desquamated in flakes a quarter of an inch in length or only slightly less. After this profuse condition had subsided or almost subsided, she began to desquamate again, and the whole of trunk with the exception of the shoulders was involved—some of the flakes being about an eighth of an inch long, but mostly furfuraceous. Her length of stay in hospital was 106 days.

Case VII.—M. H., female, *æt.* 10, admitted on the fifteenth day of disease. Temperature on admission 103.4°F., subsided by regular remissions, and fell to normal on the twenty-seventh day (Widal's reaction positive.) Spots plentiful on chest and abdomen. No diarrhoea, deafness, spleen easily felt. Desquamation (date not given) took place in large flakes from the lower half of back, chest, abdomen, legs and arms.

Case VIII.—A. M., female, *æt.* 8, admitted on the eighth day of disease. Temperature on admission 103°F., the highest point reached. She appeared very ill on admission, bases of lungs congested. Tongue dry, brown, and cracked. Abdomen somewhat full, no diarrhoea, spots plentiful, but localised to lower costal margins and over both scapulae. (Widal's reaction positive.) The temperature after admission which was regularly remittent, became intermittent about the eighteenth day, and fell to normal in three days. Next day desquamation commenced, and was profuse upon the abdomen and back in flakes quarter of an inch long, and upon the arms and legs in smaller flakes.

Case IX.—D. C., male, *æt.* 45., admitted on the fifteenth day of disease. Temperature on admission 103.6°F. The fever for twenty days was of a regularly remittent type, but the night and morning variations varied two to four degrees F. It became intermittent for the next two days, when it again rose to 104°F., afterwards gradually falling by irregular intermissions until it reached normal on the forty-fifth day of disease. (Widal's reaction positive.)

Patient had a smart attack, profuse crop of spots on chest and abdomen, no diarrhoea, spleen not felt, pulse markedly dicrotic. Desquamation began on the twenty-ninth day of disease, first on the flanks, from which flakes half an inch long were observed. Two days later small flakes were shed from the legs and arms, later a fine desquamation occurred on the back, especially the lower half.

Case X.—J. R., female, æt. 27, admitted about the twelfth day of disease. Temperature on admission 103.4°F ., which after regular remissions and intermissions fell to normal on the thirty-seventh day of disease. Patient had a smart attack, a plentiful crop of spots on the abdomen, no diarrhoea, spleen easily felt, abdomen tender generally, not distended. (Widal's reaction positive.) Desquamation first noticed on the thirty-first day of disease, took the form of large flakes from the abdomen and lower half of back, and smaller flakes from the arms and legs,

Case XI.—R. B., male, æt. 16, admitted about the tenth day of disease. Temperature on admission 103.4°F . Soon became irregularly remittent, the night and morning variation being 1.5° to 4.5°F . until the twenty-first day, after which it became regularly remittent and intermittent, falling to normal on the forty-first day. Patient had a smart attack, much congestion of the bases of the lungs, abdominal distension and diarrhoea, thirteen spots were observed on the abdomen, spleen easily felt. (Widal's reaction positive.) Desquamation began on the thirty-first day of the disease, from the trunk in large flakes, some half an inch in length, and from the arms and legs in smaller flakes.

The classification of these cases by Riesman into three recognisable groups I think is quite arbitrary, but possible, although not one of my cases could be said to belong to Group II. of his classification.

It is not, I think, so much a question of variety, as of extent and intensity in the desquamation process; moreover, the arrival at a correct interpretation of the pathology relating to the process presents many difficulties. Riesman is of opinion that the condition arises from a trophic change, analogous to the falling of hair. The question thus arises, as to the latitude given to the word trophic; if it embraces sequelæ of acute and chronic inflammatory and degenerative changes other than those of the nervous system, and resulting from idiopathic, specific, toxic, chemical, nutritional, and hosts of other causes, then I think the desquamation occurring in influenza, pneumonia, appendicitis, &c., should be regarded as trophic; and if we do thus include the latter desquamations my appreciation of the term is fallacious, or differs very much from conditions generally referred to by pathologists as trophic.

CLINICAL RECORDS.

A CASE OF ACUTE CHOREA—ACUTE RHEUMATISM & CEREBRO-SPINAL MENINGITIS IN A GIRL OF 10 YEARS.—RECOVERY.*

By P. T. O'SULLIVAN, M.D.,

Physician to the South Charitable Infirmary, and County Hospital, Cork; Lecturer in Forensic Medicine, Queen's College, Cork; Examiner in Forensic Medicine, Royal University of Ireland.

† L. F., æt. 10, was admitted into the hospital on November 24th, 1905, suffering from acute chorea and acute rheumatism. She was a badly nourished, fair child with large thin-walled veins showing through her transparent skin, she had a bed-sore owing to the want of nursing during the fortnight she was ill prior to her admission.

When I saw her she was very sick, and the prognosis was very grave. Her movements rapid and inco-ordinate, to this was due the difficulty in getting her to swallow. Temperature, 100.5° , pulse practically uncountable, respirations, 60–80, with choreic spasms of diaphragm well marked, causing a great deal of

distress. Her mouth was sore, and her tongue from the incessant movement against her teeth was enlarged, excoriated and painful.

Her heart was enlarged, the apex being in the sixth interspace and half an inch outside the nipple line. She had peri- and endocarditis, the latter of old standing. The amount of pericardial effusion was small, and yielded readily to treatment. Her temperature went up to 103.4° on the evening of the 26th, then remitted to 101° for two days, on the 29th it went up again to 102.8° , it then gradually dropped and in a week became normal, remaining so until the end.

On the morning of December 5th, I noticed slight retraction of her head, and by the morning of the 7th her head was almost at right angles with her body, she developed at the same time internal convergent strabismus of the right eye. She had little or no tenderness over the cervical spines. The development of the cerebro-spinal meningitis caused such a strain upon her neck as to absolutely prohibit swallowing, she had to be fed rectally until December 29th, a period of 22 days. Her vision was good, she had slight diplopia for a few days at the onset of the meningitis.

When first admitted her urine contained traces of albumin, this disappeared when her temperature dropped, her urine being normal afterwards. Owing to the bed-sore she was nursed a good deal on her right side on a waterbed, and during the sixth week of her illness she got dislocation of the sternal end of her right clavicle, due to the softening of the ligaments of the joint.

I regret exceedingly that I was unable to get a blood culture, the microscopic examination revealing no abnormality.

The treatment consisted in applying small blisters over the 3rd, 4th, and 5th intercostal spaces, half an inch outside the border of the sternum. Her vitality at this period was so low that the blistered surfaces became almost gangrenous, and took six or seven weeks to heal. Whilst able to swallow she got a mixture containing aspirin with alkalies, and, in addition to control the choreic movements, small doses of sodium bromide. She also had 1–100th of a grain of strychnine hypodermically every sixth hour; whilst unable to swallow, the medicines were introduced rectally.

The rectal feeding was carried out very carefully, and to this I attribute her recovery. She had a wash-out enema every morning with a weak antiseptic solution; her rectum was then rested for an hour, and six and often eight ounces of food were introduced slowly through a soft rubber catheter and funnel, under gentle pressure; in this way the rectum tolerated the above quantities of nutriment. For 22 days she was thus fed, showing that the nursing was of the highest character.

At this date (February, 4th) the child is comparatively well; her heart is damaged, but compensation is good and she has no inconvenience; the squint is improving; the dislocation of her clavicle cured itself when she was placed on her back again.

The clinical picture presented in this case is of extreme interest. I have seen meningitis develop in cases of rheumatic fever and end fatally. I have never seen cerebro-spinal meningitis as a complication in such cases, and the question arises as to whether the micrococcus rheumaticus was the primary source of infection in this case? The case undoubtedly points to specific infection, and I am of opinion that all three conditions arose from the one specific organism.

We understand that Mr. Jonathan Hutchinson has a book in the press, "On Leprosy and Fish Eating." It comprises statements as to the history of leprosy, its nature, its prevalence in different countries, and the conditions under which it has disappeared from many. Facts are brought forward to show that it is not ordinarily contagious, and that its real cause is the use as food of badly cured fish. The publishers will be Messrs. Constable and Co., Limited.

* Read before the Cork Medical and Surgical Society on February 14th, where patient was shown.

THE OUT-PATIENTS' ROOM.

GREAT NORTHERN HOSPITAL.

GANGRENE OF A DEFORMED THUMB.—A man, *æt.* about 20, was sent up to Mr. Peyton Beale with the following history: As a result of a fall from a bicycle a fortnight previously, he had received a severe lacerated wound of the thenar eminence. He reported that there had been very considerable hæmorrhage, which, from his description, was clearly arterial and seemed as if it had been from the superficialis volæ. The present condition was one of commencing gangrene of the whole of the terminal phalanx of the thumb extending upwards to the proximal phalanx. The wound itself was rather at the base of the thenar eminence, and, though septic when first seen, there was no reason to suppose that the sepsis was in any way the cause of the gangrene. An examination was made to elucidate the position of the vessels in the neighbourhood of the thumb; the radial artery was quite normal, but there was every reason to suppose that the Dorsalis pollicis and the Princeps pollicis were absent, the small muscular branches of the superficialis volæ being practically the only supply to the thumb. On looking at the thumb of the other hand, a very marked deformity was found in the shape of a supernumerary digit, in appearance like a little finger, having a perfect terminal phalanx and nail but only a rudimentary proximal phalanx. This did not appear to articulate by a joint with any of the bones of the thumb, but simply appeared as a bud contiguous to the proximal phalanx of the thumb. No other congenital abnormalities appeared to be present in the patient, and there seemed little doubt that the gangrene was due to the severing of the only artery which happened to be present to supply the thumb.

STRICTURE OF THE SIGMOID FLEXURE.—A woman, *æt.* about 25, presented herself suffering from very marked distension of the abdomen and chronic constipation. The latter was an old trouble of four or five years' duration, and had been getting steadily worse and for the last week the patient had passed no motion. She had never passed any blood, nor had she had any pain. When the abdomen was examined, with the patient lying on a couch, a distinct tumour about the size of a hen's egg was felt apparently in connection with the sigmoid flexure; the tumour was freely movable, and nothing in the shape of enlarged glands could be felt. On examination of the rectum it was found to be empty and considerably ballooned, but no tumour could be reached. The patient had not the aspect or the history of one suffering from malignant disease, nor did she look more ill than would be expected in a person who had suffered from complete obstruction for a week. Mr. Beale remarked that this seemed like a case of non-malignant stricture probably resulting from the slow cicatrisation of an annular ulceration of the sigmoid. He considered the best treatment in such cases was as follows: (1) To perform right inguinal colotomy, bringing out the upper part of the cæcum and opening it on the second or third day; (2) in three weeks' time to cut down on the sigmoid, excise the stricture with one and a half inches of healthy bowel on each side of it, and to perform an end to end anastomosis, by far the easiest, quickest, and most efficient method being, he thought, that of Maunsell's; during the time which elapsed between the colotomy and the excision of the stricture, the colon and the rectum should be thoroughly irrigated daily so as to keep both empty and clean. (3) In the course of a fortnight or three weeks to close up the cæcal colotomy wound and drop the cæcum into the abdomen. This process, he pointed out, might seem a somewhat long and complicated one, but by following it one could ensure—(1) a rapid relief of the obstruction; (2) that when the stricture was exposed to view the bowel on either side of it would be of the same diameter and practically empty; (3) an end to end anastomosis could be performed

much more rapidly through a fresh wound than through a wound which had been used for colotomy, and he ventured to think that although the patient would be subjected to three operations she would suffer much less from shock than if the whole procedure was carried out in two stages, at any rate, that was the result of his experience in many similar cases.

OPERATING THEATRES.

GUY'S HOSPITAL.

OPERATIONS FOR CHRONIC INTESTINAL STASIS AND ITS RESULTS.—MR. ARBUTHNOT LANE operated on a woman, *æt.* 36, who had suffered from the above condition for a very long period of time. Within the last three years she had rapidly lost flesh, which had become much more marked in the last few months. She looked a great deal older than her age, her skin had become dark and patches of a deeper taint had formed in and about the eyelids, temples, and over all areas exposed to friction, such as the neck, the folds of the axilla, the prominences of the spinous processes, the waist, &c.; she suffered greatly from headache, lassitude and total inability to perform her household duties. Her mental condition was one of considerable depression—she complained also of a great deal of tenderness in the right iliac region, in her pelvis, the right sacro-iliac synchondrosis posteriorly, and below her last rib; in this last situation her pain was of a dragging character, when in the erect position and when in the supine position of a dull aching character, also she had pain in the position of the sigmoid which was converted from a mobile loop into a rigid fixed piece of bowel which was very tender on pressure; at times this last pain became very severe and griping, which was probably due to the passage of faecal matter, through the narrowed and telescoped sigmoid. The cæcum and transverse colon were felt to be very much distended, and displaced downwards into the pelvis. Her constipation was very considerable, her bowels having never been opened except with medicines, and then only when drugs were taken in large quantities. The patient also had clinical and physical evidences of dilatation of the stomach, and of a retention of a considerable quantity of fluid in the small intestines. Most of the symptoms of which she complained became more marked as the day went on, and her day practically ended at about one or two o'clock, as after that time she felt quite unfit to do any work. She was very anxious for some operation to be done which might alleviate her misery. Consequently the abdomen was opened in the middle line, the ileum was divided within a few inches of the cæcum, its proximal end being closed; the termination of the ileum with the cæcum, ascending and transverse colons was removed, and the large bowel closed at the splenic flexure; a communication was next established by lateral anastomosis between the end of the ileum and the rectum, which was then fixed by sutures to the right side of the pelvis, in order to make the most convenient passage of the contents of the ileum into the rectum.

The patient is now progressing very satisfactorily.

The next case of chronic overloading of the intestines occurring in a woman, *æt.* 38, was of an unusual type, in that the sigmoid loop had not become telescoped, atrophied and fixed, but had instead become much elongated, hypertrophied, and dilated, forming a loop of very considerable size. It was obvious that this loop frequently experienced much difficulty in emptying its contents into the rectum, but as far as one could gather the obstruction had never been complete

for a sufficient length of time to produce symptoms of acute obstruction. The symptom which, however, caused her most discomfort was an enormously dilated stomach, for which she had been under treatment in the medical wards for some time. The abdominal cavity contained a large quantity of fluid. It appeared, as if the dilatation of the stomach was secondary to the descent of the transverse colon, and was a consequence of the chronic constipation from which she had suffered for so long. The patient was exceedingly feeble. On opening the abdomen a very large quantity of fluid escaped. The presence of fluid appeared to be due, Mr. Lane observed, in part to the distension of the stomach and in part to the dilatation of the big bowel. Situated in the concavity of the stomach was a gastric ulcer which was quite free of the pylorus. The acquired ligaments or peritoneal bands which develop in cases of dilated stomach, and which hitch up its pyloric end and the first piece of the duodenum and so obstruct the exit of the contents of the stomach, were, Mr. Lane pointed out, remarkably well developed. The patient's condition did not permit of any other operation but a gastro-jejunostomy, which immediately afforded her relief from the symptoms due to the dilatation of the stomach.

The patient, unfortunately, got some bronchitis a day or two after operation, which in her very enfeebled and emaciated condition naturally caused some anxiety.

SPECIAL ARTICLE.

THE SANATORIUM TREATMENT OF CONSUMPTION IN IRELAND.

THESE are at present under discussion schemes for the establishment of sanatoria for tuberculosis in several parts of Ireland. In Cork the scheme has been in hand for some years, and is at the moment held up on the question of a site. In Belfast and Dublin, as well as in some country districts, local authorities are discussing the advisability of establishing public sanatoria. Under these circumstances it is inevitable that the question should rise in Ireland, as it has in England, as to whether sanatorium treatment is justifiable.

There are several functions claimed to be performed by sanatoria, any one of which may be sufficient to justify the expenditure of private or public money. To sum these in a sentence, they are the curative, the educative, and the segregative influences exerted. It is the last of these which is most likely to appeal to local authorities in control of the public purse. We have not quite got to the stage when it is admitted to be a part of public policy to provide care for the sick other than the sick poor, or to spend large sums of money in spreading hygienic knowledge. The community has, however, now for many years been in the habit of controlling the spread of infective disease at the public expense, and viewed from this standpoint there can be no theoretical objection raised to the provision of sanatoria for tuberculosis. The more consumptive patients are kept in sanatoria the less the disease is spread, and it is even conceivable that by a careful supervision of every consumptive patient, if that were possible, the disease might be totally eradicated. With regard to the curative and educative functions there may be more question, and it is in this relation that the Medical Report of the Royal National Hospital for Consumption at Newcastle will be found to contain information of peculiar interest. It is notoriously difficult to furnish statistics of any value on the sanatorium treatment of consumption, since there is no uniform or conventional set of standards by which the results of different observers may be compared. The Hospital at Newcastle, however,

has had the advantage of being under the control of the same Resident Physician, Dr. Steede, since the beginning of its work ten years ago, so that, at any rate, the same system of classification has been applied to a fairly large number of cases. This system is described as follows:—

"As in previous years, we divide the patients into four classes, according to the stage of disease on admission. This classification is of course arbitrary. The objective signs on which it has been made are somewhat as follows:

"A 'comparatively early' case has signs of slight consolidation, and has, in at least two lobes, crepitation on coughing; or has somewhat more advanced disease in one lobe, and no (or very slight) signs elsewhere. A typical 'moderately advanced' case has early cavity formation in one lobe, with crepitation also in two other lobes; or with more advanced but less extensive signs (as, for example, early cavity formation in both apices, and lower lobes quite free). All who have less signs than a 'comparatively early' case are classed as 'incipient.' All in whom the signs are more developed than in the 'moderately advanced' case are classed as 'advanced.'"

Of course, as the Report goes on to point out, some cases are met which do not easily fall into any of these classes, but it is impossible to devise any system to which the same objection does not apply.

Of the 62 "incipient" cases treated during the year with an average stay in hospital of eleven weeks and five days, 19 were discharged "very much improved," 23 "much improved," 18 "improved," and 2 "unchanged." Of the 144 "comparatively early" cases, 8 were discharged "very much improved," 49 "much improved," 71 "improved," 11 "unchanged," and 5 "worse." It is to be noted that the medical staff wisely avoided designating any patient as "cured." Nevertheless, they bring abundant evidence in the history of cases treated eight or nine years ago, that the improvement which was then obtained has persisted to the present time. Many of these earlier patients write to say that they feel perfectly well, and that they have been able to work without interruption.

Nearly all these old patients keep up what they call "the Newcastle treatment," that is to say, open-air life, and some of them mention the fact that their example has been followed with good effect by other sufferers. As the Report remarks:—

"Patients who enjoy sleeping in the open, either on verandahs or under a tent, with the sides open all round, will not willingly return to stuffy rooms. On his return home a patient not infrequently improvises an 'open-air shanty' for himself; and we frequently hear that other old patients have 'taken out the windows.' Every patient on his discharge is given a leaflet containing short and clear instructions about the management of his expectoration, and the importance of fresh air, &c.

"Amongst the general public, a just appreciation of the value of 'fresh air' in the sanatorium sense is more common than formerly, and sanatoria may justly claim a very large share of the credit for this important change in the minds and, to some extent, in the habits of the community. Sanatoria have demonstrated that what was almost universally considered dangerous and harmful is, in reality, useful and beneficial; and, even in this way alone, have done, and are doing, an untold amount of good. Even without considering 'economic cures,' and direct benefits conferred on patients, we believe that this consideration alone—namely, the influence sanatoria have on public opinion, medical and lay—affords in itself a sufficient answer to the question sometimes asked: 'Is the sanatorium treatment worth while?'"

We have touched on but a few points in a Report, whose judicial sobriety and conscientious compilation render it of value to all interested in the problem of tuberculosis.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, MARCH 9TH, 1906.

The President, Mr. CLUTTON, in the Chair.

DR. HERBERT FRENCH and Mr. C. B. TICEHURST read a note upon the

RELATION OF TRAUMATIC DIABETES INSIPIDUS TO GLYCOSURIA.

The patient, a man, *æt.* 44, was himself shown to the Society. Five years ago he had been thrown off his bicycle, remaining unconscious for 14 days, with cerebro-spinal fluid dripping from his nose. On recovery bilateral temporal hemianopia and ocular pareses showed that he had fractured the base of his skull in the region of the optic chiasma. Previous to the accident he had been perfectly well; after it he suffered from extreme polyuria and thirst, passing up to 10,000 cc. of pale urine, sp. gr. 1004.6, free from albumin and sugar. The expectation that the "sugar centre" in the medulla was also injured led to an extensive metabolism research in which all food and excreta were analysed. By increasing the carbohydrates in the food it was attempted to produce glycosuria. Dextrose, starch, and cane sugar were all assimilated well, up to as much as 700 grains (dry) of carbohydrate in 24 hours. No sugar could be made to appear thus in the urine. Two years later, however, glycosuria developed spontaneously. The urine remained of comparatively low specific gravity. Careful dieting diminished the sugar passed, but did not entirely prevent glycosuria. Upon careful dieting, both acetone and diacetic acid were present as well as sugar. On ordinary diet there were no acetone and diacetic acid. The patient feels weak and is unable to carry on active work; but his weight is well maintained, and if he could see better he could carry on an occupation which was not very strenuous. Similar cases were quoted from the literature, but none exactly like this one could be found. Injury as a cause of either form of diabetes was not very common, and the association of the two forms together was very rare.

Dr. A. E. GARROD remarked on the peculiar features of the case, in its tendency towards recovery, and yet in the long duration of the glycosuria from such a cause. Traumatic glycosuria usually lasted only until the glycogen reservoirs were emptied. He referred to the general obscurity prevailing on the subject of non-diabetic glycosuria.

Dr. FARQUHAR BUZZARD asked whether there were in the literature any other cases similarly present with localising brain symptoms.

Dr. FRENCH in reply, said that there were two such cases recorded. It had been suggested that the condition might be due to an injury of a hypothetical "thirst" centre, the polydipsia and polyuria being secondary.

Dr. E. FARQUHAR BUZZARD and Mr. JOSEPH CUNNING read a paper on a case of

POST-TRAUMATIC HÆMORRHAGE FROM THE SUPERIOR LONGITUDINAL SINUS WITHOUT FRACTURE OF THE SKULL; OPERATION AND RECOVERY.

On April 1st, 1905, a man, *æt.* 25, fell on the back of his head and inflicted a small scalp wound which healed without trouble. A fortnight later he complained of continuous and increasing headache, and on examination showed no physical signs except an extensor response and a diminished abdominal reflex on the left side. In the course of the next few days he developed complete left hemiplegia and hemianæsthesia with stupor and slow pulse and vomiting, but no optic neuritis. On April 18th he was trephined over the right post-parietal region and a large accumulation of blood was found beneath the dura mater and rapid hæmorrhage taking place from the neighbourhood of the superior longitudinal sinus. Forceps were placed on the bleeding point and the patient given a

saline infusion. On April 30th, the forceps were removed, and on April 2nd improvement in the paralytic condition set in. This has progressed to a complete recovery. Reference was made to the extreme rarity of bleeding from the superior longitudinal sinus without fracture of the skull and to the slow development of symptoms as its result. The slowness of the recovery was probably due to œdema of the brain substance.

Mr. PEARCE GOULD remembered seeing Mr. Christopher Heath operate successfully on such a case; there were no paralytic symptoms.

Mr. J. E. SPICER, introduced by Dr. PERCY KIDD, exhibited a pathological specimen showing

UNUSUAL DILATATION OF THE STOMACH FOLLOWING HOUR-GLASS CONTRACTION.

The patient, a woman, *æt.* 37, had suffered from dyspepsia more or less continuously for twenty years, and had vomited blood on three occasions. On February 15th, 1906, she was admitted to the London Hospital under Dr. Percy Kidd with an increase in the severity of her symptoms, and signs pointing to dilatation of the stomach. Four days later she suddenly developed general peritonitis and died in three hours. The *post-mortem* examination showed a constriction in the stomach in the neighbourhood of the pylorus. The peritoneal cavity contained between two and three pints of a thick green fluid resembling thin spinach, which was oozing from a perforation in an old ulcer situated in the constricted portion. The proximal portion of the stomach was much the smaller, and contained about 10 ozs. of partly digested milk. The distal portion contained several pints of thick green fluid such as was found in the general peritoneal cavity and formed the large swelling that had been felt during life. Its axis lay roughly at right angles to that of the proximal portion with the perforation on the anterior wall of the connecting passage. The opening into the duodenum was found in the outer wall of the angle, close to the perforation also. The perforation had been closed over by a thin lip of the lobe of the liver, the adhesions between the two having only recently been separated.

The PRESIDENT remarked on the importance of operating in such chronic cases.

Mr. ROUGHTON asked why no operation had been considered (a) to relieve the dilatation, and (b) after the occurrence of perforation.

Dr. PERCY KIDD said that he had not seen the patient before admission, and that then her general condition was good. He referred to the curious sac formed at the pylorus, and suggested that it might have originated in a congenital *cul de sac*.

Dr. GARROD drew an analogy between the condition and œsophageal diverticula.

Mr. SPICER said that he had been called up at two a.m. and found the patient moribund; she died two hours after.

Dr. A. E. GARROD and Dr. LANGMEAD read the notes of a case of

ASSOCIATED CONGENITAL MALFORMATIONS, INCLUDING TRANSPOSITION OF THE VISCERA.

These occurred in a female infant, *æt.* 9 months, who was admitted into the Hospital for Sick Children, Great Ormond Street, under Dr. Garrod for wasting and constipation. An operation had been performed for imperforate anus when the child was 24 hours old. She was a badly nourished, ill-developed child, and was pale, but showed no cyanosis or clubbing of the fingers. Her appearance was characteristic of the Mongolian type of idiocy, from which it only differed in that the back of the head was slanting and not flat. Examination revealed the heart to be situated on the right side and the liver on the left, an observation confirmed by a skiagram (produced). A systolic murmur was heard

over the normal mitral and aortic areas and behind the sternum, and also in the back. *Post-mortem*, complete transposition of viscera was found. The heart, as well as being misplaced, was malformed. There were present a patent foramen ovale, an imperfect septum ventriculorum, and a patent ductus arteriosus. The upper lobe of the right lung was missing. They remarked that in this case were thus associated, four distinct congenital malformations—viz., imperforate anus, a congenital heart lesion, complete transposition of viscera, and idiocy of the Mongolian variety. Of these the two first were definitely malformations of arrest, none of them were malformations of excess. That in some instances the cardiac lesion met with in such associations is not an anomaly by arrest, but is one of those which have been ascribed with some show of reason to the occurrence of foetal endocarditis. They thought that it might be as Rokitansky suggested, that a primary malformation predisposes to foetal endocarditis, since there is certainly evidence to show that malformed valves have some special liability to the *post-natal* lesions of ulcerative endocarditis. They considered that transposition of viscera was not infrequently associated with other malformations, and referred to a paper written by Dr. Garrod eleven years ago, in which were quoted several cases from the literature, in which transposition was accompanied by malformations in addition to congenital heart lesions. In conclusion, they considered that this case afforded an example of an association of quite special frequency—viz., that of congenital heart lesions with Mongolian idiocy, an association pointed out by Dr. Garrod in 1899, and confirmed by a number of other observers since. They stated that it is in the outpatient department of children's hospitals that this association is seen, for such children seldom survived the first year or two of life, and so it is seldom observed in asylums among Mongolian idiots, who have passed the age of five years.

The PRESIDENT said that in his experience congenital deformities occurred in first-born children, or in children born when the mother was exhausted, by either too frequent or too many pregnancies.

Dr. GARROD pointed out that this was not in trend with modern Mendelian views as to heredity, but that it was well worthy of investigation.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, FEBRUARY 23RD, 1906.

MR. G. S. GUNN, F.R.C.S., in the Chair.

APPENDICITIS.

MR. D. KENNEDY read a paper on the above subject. He strongly advocated operation in the course of the disease as being calculated to shorten the illness and reduce the mortality. He gave a brief history of eight cases out of a series of forty-three, upon which he had operated during the acute stage without a death. The dangers of operating during an acute attack, he believed, were greatly exaggerated. Unless complications were present, appendicectomy was as safe during the attack as in the quiescent period. The ideal operation was removal of the offending structure. If pus were present, free drainage should be provided. Mr. Kennedy condemned indiscriminate douching and rough sponging of the peritoneum. The diagnosis of the disease was frequently difficult in children, and a proper examination could only be made in these cases by the aid of an anæsthetic. In all cases he recommended a rectal examination and in females a vaginal examination, when possible, for diagnostic purposes.

Mr. GUNN referred to the importance of a leucocyte count in coming to a diagnosis, and recommended the employment of palliative measures before urging operation.

Mr. A. B. MITCHELL (Belfast) alluded to the difficulty

sometimes experienced in diagnosing appendicitis in an early stage. He had seen the condition confounded with perforation of a duodenal ulcer. He thought it advisable to remove the appendix in suppurative cases, and also at a very early period if the disease were diagnosed with certainty. Failure to remove the appendix might lead to recurrence with abscess formation.

Dr. SAVAGE mentioned some facts illustrating the connection between appendicitis and suppuration elsewhere in the body. In one case he thought an attack of appendicitis had followed upon follicular tonsillitis ending in suppuration.

Mr. A. B. MITCHELL read a paper on Excision of the Scapula for Neoplasm. He described in detail the steps of the operation, laying emphasis upon the more important points. The patient was exhibited and demonstrated the range of movement and the functional capacity of the limb. Skiagrams of the affected scapula taken before operation, were presented for inspection.

The communication was discussed by Sir Thomas Myles, Mr. Kennedy, Dr. Johnston and Dr. Goulding.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD, THURSDAY, MARCH 8TH, 1906.

MR. PRIESTLY SMITH, F.R.C.S., President, in the Chair.

MESSRS. J. HERBERT PARSONS and GEORGE COATS read a paper on a case of

ORBITAL ENCEPHALOCELE ASSOCIATED WITH MICRO-PHTHALMIA.

Mr. Parsons had shown the child to the Society when 13 weeks old. There were then large cyst-like masses in the right orbit pushing the globe over to the outer side. The right eye was evidently microphthalmic and showed ophthalmoscopically a coloboma of the nerve entrance, and also of the macula. Various diagnoses were made as to the orbital condition. As the tumour was increasing in size it was operated on, but the child died a few days later. The mass in the orbit consisted of brain tissue which pressed upon, and caused deformity of the globe. It was connected with a large mass of brain substance within the skull which lay beneath the frontal lobe. The intracranial mass had displaced the latter upwards, and the temporal lobe backwards, but had no connection whatever with either. It was therefore believed to be either a teratological inclusion, or a piece of brain substance snared off in early foetal life, possibly from the region of the caudate nucleus, and growing independently. The eye showed three deformities, each of which was rare. (1) An ectasia on the nasal side of the papilla, which still had a lining of stretched choroid and normal retina (2) a coloboma of the nerve entrance which was peculiar in being on the temporal side of the nerve and in being entirely within the area of the porus opticus; (3) a macular coloboma which consisted chiefly in a partial defect and depigmentation of the pigment epithelium, both the choroid and retina being almost intact. The relation between the encephalocele and the abnormalities of the globe was discussed.

Mr. PRIESTLY SMITH described a Scotometer for the diagnosis of glaucoma and for other purposes. It was intended to facilitate the examination of the central parts of the field of vision, especially in cases of suspected glaucoma. It consisted essentially of a disc of millboard covered with black cloth and figured on the back with the degrees of the circle. The test object was a small cutting of grey wool which was laid upon the cloth at any desired distance from the centre. In the case of suspected glaucoma it should be placed at 25° from the centre, as shown by a faint mark on the cloth, and the disc should then be slowly rotated. Should it nowhere disappear or grow dim in all probability glaucoma does not exist, for, as Bjerrum had shown the defect; in the glaucoma field was almost always radical or sector like, and, with a delicate test

could be traced inwards. If a defect were found its extent should be noted on the graduated circle so that it could be used for future comparison. Other circles could be explored if necessary. The authorised maker of the instrument is Mr. Bailey of Bennett's Hill, Birmingham.

Mr. C. WORTH read a paper on

HEREDITARY INFLUENCE IN MYOPIA.

Though often regarded as a simple error of refraction grave complications may arise which altogether overshadow the original condition. Myopia is frequently inherited. In a series of 687 cases examined by the author, 33 were malignant and 654 were uncomplicated. Of the latter 56 per cent. gave a family history of myopia, while of the former in only 24.25 per cent. was evidence of heredity found. In one family, whose pedigree was shown, nearly all the males were myopic and none of the females; but the myopia was transmitted through the female line. The amount was in all cases examined about the same—viz., 10 to 12 D with some astigmatism. The fundi showed crescents, but grave complications were wanting. Curiously enough in this family all the healthy eyes were blue, and all the myopic ones were brown. Night blindness was only admitted in one family. The statistics of the 687 cases were as follow:—Of 313 with no family history of myopia, 163 were males and 150 females. Of 374 with a family history of myopia, 228 were males and 146 females. This showed the usual preponderance of myopia in men was increased in those in which myopia was hereditary. Of the 374 cases in which a family history of myopia was obtained, in 159 the parents were myopic, but the myopia was present in uncle, aunt, or grand-parent. The fault was on the mother's side in 104 cases, on the father's side in 33 cases, and on both sides in 32 cases.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, MARCH 1ST, 1906.

MR. FRANK T. PAUL, F.R.C.S., President, in the Chair.

EXHIBITION OF CLINICAL CASES.

DR. T. R. BRADSHAW showed, amongst several other cases of interest, (1) a case of paralysis of both 6th nerves in a young woman from whose neck cancerous glands had been removed; (2) congenital heart disease, with cyanosis, drumstick fingers, and systolic murmur at base; (3) disseminated sclerosis in a boy 19, after pneumonia—the symptoms were ataxy of legs and arms, brisk reflexes, scanning speech, but no nystagmus.

DR. A. G. GULLAN showed a man of 27, with complete transposition of the viscera. The man enjoyed excellent health and had been through the South African War.

Dr. Gullan also showed two cases of exophthalmic goitre, which had improved under the treatment of rodagin in drachm doses.

DR. NATHAN RAW showed cases of mitral, pulmonary, and aortic stenosis respectively, two of myxœdema, and one of arsenical neuritis.

THE PRESIDENT exhibited a patient upon whom he had performed orchidopexy for crypt-orchidism.

DR. G. STOPFORD TAYLOR exhibited a case of mycosis fungoides in which all evidence of the disease, except some pigmentation, had disappeared after treatment by the X-rays. Fifteen exposures of ten minutes' duration, each equal to a Holzknicht's unit, were administered, two exposures being given each week. The diagnosis had been confirmed by a microscopic section of the growth.

DR. F. H. BARENDT exhibited a man of 22 with seborrhœa corporis caused by wearing a vest continuously night and day for a fortnight in spite of free perspiration during work. The eruption consisted of discrete macules—salmon-coloured—marginate and

slightly scaly—scattered over and limited to the anterior and posterior aspects of the trunk.

DR. LESLIE ROBERTS showed cases of lupus, keloid following syphilis and follicular epithelioma.

DR. A. C. BERNARD a case of digital primary syphilis with secondary manifestations.

DR. K. GROSSMANN showed a case of albinismus confined to the iris, the structures of which with the exception of the uveal layer were free from pigment. The pupils were both excentric, indicating congenital displacement of the lenses which caused slight horizontal astigmatism. Horizontal nystagmus was present and, in the left eye, capsular cataract. The hair and fundus oculi were pigmented throughout.

MR. R. J. HAMILTON showed (1) a case of ptosis and paresis of the external rectus in the right eye and paresis of the left inferior rectus; (2) persistent increased tension in the eye of a girl of 18 years of age after removal of traumatic cataract. Iridectomy had failed to give more than temporary relief.

APPENDICITIS.

THE PRESIDENT read a paper on this subject in which he discussed the relative success of early and "interval" operations. Everyone agreed in operating at once in cases which suppurated, or in which general peritonitis supervened; but, apart from these complications, interval operation as recommended by Sir Frederick Treves was the goal to aim at. Statistics were wanting as to the mortality from appendicitis when an early operation was uniformly undertaken, but from what he had seen of it he was sure that the death-rate was much higher than when uncomplicated appendicitis was properly treated through the attack and appendectomy done on recovery. In any statistics it was necessary to consider the mortality as a whole. Since his previous paper five years ago, he had operated on 252 cases, including 43 abscess and 17 peritonitis cases. The mortality was 6.3 per cent. During the last year there had been considerable improvement. For 72 cases, including 16 abscess and 4 peritonitis cases the mortality was 2.7 per cent. For interval operation there should be practically no loss of life and very little in abscess cases if taken early and the appendix not removed. In general peritonitis the results were improving but the mortality was still high. Early operation might save a few cases from fatal complications, but was itself a cause of greater loss of life. For those who adopted the view that early operation was the best there should be no half measures; the essence of the practice was immediate operation in every case; it was a comfortable doctrine and saved the surgeon from all anxiety as to the right time to operate, but he could not subscribe to it as he felt sure it was not the best thing for the patient.

MR. R. W. MURRAY spoke in favour of early operative interference. In an urgent case the operation should be performed at once; if the symptoms were of a less urgent nature the operation might be postponed for a few days. The dangers of the operation were known to be slight, and were for the most part avoidable, whereas the dangers of delay were unknown and unavoidable. He considered the administration of morphia inadvisable, for the drug tended to impair the movements of the intestines, and the great omentum, which had been proved to contain a host of phagocytes, depended upon the intestines for its locomotion, and might thus be prevented from arriving at the seat of the disturbance and so from localising the trouble.

MR. E. M. STOCKDALE thought that the improvement in the statistics of general peritonitis might be attributed to the fact that cases were nowadays sent earlier to the surgeon, so that more cases might be classed as "diffuse" rather than "general" peritonitis.

He related the case of a youth of 20 who died within ten hours of the bursting of an abscess in connection with the appendix, the symptoms of general septic absorption being so severe as to preclude operation.

MR. G. P. NEWBOLT considered that the Trendelenberg position with the patient lying on the left side, prevented the small intestines and omentum from

getting into the way and much facilitated the operation. He drew attention to the occurrence of bladder symptoms in the early stages of the attack, and remarked that it was often the best plan to separate the appendix from the base to the apex in troublesome cases. He favoured the interval operation and did not remove the appendix in cases of suppuration unless it lay exposed in the cavity of the abscess.

Mr. W. BLAIR BELL would remove every appendix within twenty-four hours of the onset of an attack, if the case were seen in time. There was no more danger in this proceeding than in the "interval" operation, while it was the means of saving cases which might go from bad to worse; further it did away with the possibility of abscess formation, faecal fistula, hernia, &c. Concerning the after-treatment, he thought that the use of frequent saline injections per rectum added to the patient's comfort and prevented various thromboses.

Mr. T. C. LITTLER JONES, while congratulating Mr. Paul on the gratifying results he obtained by the "interval" operation, pointed out that the whole difficulty lay in diagnosing those cases which would go on to suppuration or general peritonitis. At all times he relied on the pulse for guidance and made a point of examining the rectum in every case. He also drew attention to a discharge of mucus which preceded perforation of the bowel. Unless the peritoneal fluid was of that abundant thin, easily diffusible character which had already, probably, infected every part of the peritoneum, he did not wash out but relied on careful swabbing.

Dr. A. G. GULLAN said that the great majority of cases of acute appendicitis treated by absolute rest, starvation diet, and rectal enemata recovered; he believed small doses of morphia were of great benefit, provided the temperature and local conditions were more closely watched. He never gave purgatives. He agreed with the President that the interval was the best time for operation on recurrent cases.

Sir James Barr, Mr. Damer Harrison, Captain Douglas, Dr. J. Hill Abram, Dr. E. T. Davies, Dr. H. Harvey, Dr. A. E. Davis, Dr. G. Westby and Dr. R. J. M. Buchanan also took part in the discussion.

Paris, March 10th, 1906.

KERNIG'S SIGN.

ALTHOUGH the description of Kernig dates from 1884, the sign which bears his name was not generally known before 1898. It was at that period that it was considered an almost pathognomic symptom of meningitis. However, a reaction soon occurred, for this sign was found, after careful research, in a host of other affections, as typhoid fever, pneumococcal infection of the lungs, pneumonia, tuberculosis, sciatica, hemiplegia, etc.

According to Sinton and Voisin, Kernig's sign should be sought for as follows: The patient lying on the back, an assistant places his hands on the thighs to prevent any flexion; if the patient is told to sit up, he is unable to do so.

By another method, the patient is placed in the sitting posture in the bed, and the hands of the attendant endeavour to press on the thighs to obtain complete extension of the lower limbs so as to adapt them exactly to the surface of the bed. Where the sign exists this extension is impossible, the leg remains flexed on the thigh no matter how strong are the efforts to overcome the contraction of the articulation of the knee.

Where the contraction of the neck and the back prevent the patient from sitting up, an endeavour will be made to bend the thigh on the pelvis by maintaining the limb in complete extension.

The same sign has been described by Chauffard as affecting the upper extremities in a case of cerebro-spinal meningitis.

As soon as the patient sits up, says this author, the arms become rigid, contracted, in a half-flexed position impossible to correct this attitude even by employing considerable effort, all these phenomena disappear as if by enchantment as soon as the patient lies down.

Kernig's sign may be met with in about three-quarter of the cases of tuberculous meningitis. It is modified according to the progress or the recession of the inflammatory process and seems to coincide with the absence of reflex of the rotula.

The value of the sign is especially interesting in the latent forms of meningitis and even in infantile paralysis. It should be completed by the lumbar puncture and the cytologic examination of the rachidian liquid.

In all general affections the sign of Kernig may be observed where symptoms of brain excitement are present and in particular in typhoid fever, pneumonia, purulent pleurisy, gastro-intestinal affections of children, uremia, medullary affections, hysteria, hemiplegia, cerebral abscess, chronic encephalitis, locomotor ataxy, lumbago, sciatica.

The nature of the symptom is evidently a contraction of the flexor muscles of the leg.

Different theories have been expressed to explain the phenomenon. Some authors believe the cause to be due to an exaggeration of the muscular tonus, while others pretend that it is produced by hypertension of the cephalo-rachidian liquid. This explanation, however plausible, does not hold good, as Kernig's sign is seldom or never observed in cases of hydrocephalus.

For Kernig himself, as well as Dieulafoy and Netter, maintains the sign is due to local irritation of the spinal medulla and the cauda equina.

ACUTE NEPHRITIS.

Prof. A. Robin recommends the following treatment for acute congestion or œdema of the kidney. Blood letting when possible no diuretics in the acute stage, neither milk nor infusions which only go to stimulate an organ that cannot work. Instead of provoking the function of the gland, the smallest amount possible of liquid should be given, and that only water; the patient will be allowed to drink only as much pure water as is necessary for his thirst. Wet cupping should be applied over the renal organ or better still seven or eight leeches and a drastic purgative given.

If the action of the purgative is not sufficient the following mixture may be ordered, of which a third part is taken every fifteen minutes.

Jaborandi leaves, 1 drachm.

Proof spirit, 2 drachms;

After one hour's maceration

Add boiling water, 6 ozs.

A half-hour after the absorption of this medicine, the patient commences to salivate, and in a few minutes profuse sweating sets in, while the salivation becomes very abundant. Unfortunately, jaborandi causes sometimes vomiting. But M. Mollière, of Lyons, has remarked that an ointment of pilocarpine applied over the whole surface of the abdomen and lumbar region, and covered with a sheet of impermeable tissue provokes abundant sudation and salivation—

Hydrochloride of pilocarpine, 2;

Vaseline, 10 oz.

To stimulate the liver, which plays an important role in the excretion of different substances, the patient will be ordered 6 to 10 capsules of ether daily. Cold enemata may be ordered to stimulate the intestines and the patient will inhale oxygen gas.

For dyspnoea, inhalations of nitrate of amyl are indicated, and very small doses of digitalin (5 drops daily of 1-1,000 solution).

At the end of a few days, diuresis will set in, which

may be facilitated by theobrimin, at the dose of ten grains twice or three times a day.

UTERINE FIBROMA.

For women suffering from fibroid tumours, ten grains of powdered sabina given every morning for months and years will relieve the pain, diminish the volume of the tumour, and regularise the menses. The patient should remain in bed during the menstrual period, and the treatment should be suspended three weeks every two months.

GERMANY.

Berlin, March 10th, 1906.

FIBROLYSINE IN GYNÆCOLOGICAL PRACTICE.

This subject is treated in a paper in the *Korr. Bl. f. Scherw.-Aerzte*, Feb. 1906, by Hr. Vogelsanger. He refers historically to the introduction of thiosinamine into practice by Hebra in 1892, for the softening of cicatricial contractions, and to the confirmation of Hebra's expectations by numerous observers; its use in Dupuytsen's contraction and also in affections of both eyes and ears. Its principal use was, however, internally for the relief of strictures of most varied kind—retractile processes on the valves of the heart, pleuritic adhesions, and those of the abdominal cavity.

It was used early in gynæcology in chronic parametritic exudates and the fixations resulting from them. Prof. Offergeld had, however, quite recently denied that it had any effect in these cases. In view of the generally favourable results spoken of a systematic investigation was undertaken in the Basel Women's Hospital, the preparation employed being a double combination thiosaminosodium salicylate, to which the name of fibrolysine was given. Thiosinamine was met with in white crystals, quite insoluble in water, but soluble to the extent of 20 per cent. in alcohol. It had to be given subcutaneously. A glycerine solution in warm water was proposed by Van Horn Juliusberg (Thiosn. 10, glycerine 20, water ad. 100). This was painless on being injected. The thiosinamine, however, re-crystallised on the solution getting cold, and necessitated a re-warming of the mixture.

Fibrolysine was readily soluble in cold water, and proved itself very suitable to subcutaneous injection. As the solution would not keep exposed to the air, it had been put on the market in closed glass ampullæ, containing 2.3 c.c. of fibrolysine equal to 0.2 gm. of thiosinamine. When used in the hospital it was always injected subcutaneously into the gluteal region, and the injection was generally painless.

It was used in 18 cases, and 130 injections were given in all. They were mostly cases of cicatricial contraction of the pelvic tissues; twice in cases of atrophic parametritis; four were cases of deep laceration of the cervix, and nine remains of old pelvic cellulitis.

As regarded results, which differed very much, two groups were to be recognised each embracing about a half of the cases. In the first group the effect was unmistakable, even after the first two or three injections it was noticed that the firm cicatricial bands became softer, and after six the diseased side could not be distinguished from the sound one by the examining finger. Subjective improvement went hand in hand with the objective, the symptoms gradually disappearing.

The favourable results were obtained mostly in case of laceration of the cervix and contraction of the principal uterine ligaments, not so much in contractions situated in Douglass' pouch.

In the second group the effects were not so well marked and injection rarely led to complete disappearance of the bands. These cases were generally associated with grave nervous disturbance and the parts affected were usually the utero-sacral ligaments. The two cases of atrophic parametritis posterior belonged to this group. Here also the subjective improvement was but little marked. In addition to

the fibrolysine treatment the bands were systematically stretched by massage or otherwise, and the author attributes Offergeld's failure to the omission of this necessary adjunct—the mechanical stretching.

In retro-uterine hæmatocele after tubal abortion, and in two cases with comparatively recent parametritic exudations, there was no special acceleration of absorption. Somewhat disagreeable accompaniments of the treatment were that in two cases there was a disagreeable taste of garlic after each injection, and this was also noticed when the injection was intravenous—a proof of the rapid decomposition of the fibrolysine in the blood into its component parts. In a third case, along with the disappearance of the bands and the accompanying pain, prolapse of the uterus took place, which required the application of a pessary.

Certain people had a peculiar idiosyncrasy as regarded thiosinamine (a very itchy rash after each injection). Others had observed giddiness, headache, and sickness after large doses. The injection should not be made in the cicatrices themselves, or abscesses might be caused.

ECHINOCOCCUS OF THE ORBIT.

Dr. E. Trew relates a case in *Arch. f. Augenheilk.*, of a woman who had suffered from slight exophthalmus for nine years, got suddenly worse, after an energetic digital examination the sight also failing somewhat. The œdematous conjunctiva of the lower lid projected as a crescentic swelling. The lower half of the ocular conjunctiva was also œdematous, whilst the upper halves of both conjunctivæ were normal. The eye projected so far as to be almost outside the orbit. A fairly resistant mass was felt in the orbit. This was cut down upon and a slightly nodular elastic tumour was reached, which on puncture gave exit to a clear fluid containing echinococcus membranes and numerous scolices. Eight cysts were opened altogether, and curetted. A large piece of the conjunctival swelling was removed. Healing *per primam*, the exophthalmus disappeared, mobility returned, and the vision also again became normal.

AUSTRIA.

Vienna, March 10th, 1906.

ENDEMIC ELEPHANTIASIS.

Eiselsberg presented a case of sporadic or endemic elephantiasis to the Gesellschaft. The patient was a young man, æt. 24, who had never been out of Vienna and suffered, when about eight, with swelling of the right leg about the thigh, which has now grown to enormous dimensions.

The father of the patient died of cardiac disease, but the mother and five sisters are alive and quite healthy. The present enlargement commenced, as stated, about the eighth year without any recognised cause and without any complaint, injury to sura, or other abrasion to the cutaneous surface. The swelling proceeded slowly till the fourteenth year was reached, when he went to his father's workshop for the manufacture of fancy jewellery. The lad had not long commenced his apprenticeship when he began to grow weak and feeble, till finally he could not stand or walk. By this time the feet assumed a plantar flexion till he went to bed, where he remained off and on till he was twenty-one years of age, by which time the disease had become quite stationary and admitted of renewed movement. Within the last few years repeated fever attacks have occurred with reddening and pain resembling erysipelas in the right leg. On his recent reception into hospital he was blanched and greatly emaciated about the thorax and face with every symptom of catarrh, though the heart and kidneys were found normal. Scoliosis was present with leucocytosis 22,000. The lower extremity was quite without shape from its swollen condition while the surface was strewn over with scars and excoriations. The skin was thick and hard with round hard subcutaneous nodules in the tissues. Any movement of the parts was impossible although there appeared symptoms of spontaneous

fracture at the neck of the femur. Closer examination, however, with the Röntgen rays proved that it was only a luxation of the hip joint with a diastase at the knee-joint, that is, that the femur and tibia were wide apart. The tibia and fibula seemed to diminish to a mere shadow as they descended while the metatarsal bones could hardly be observed and were widely set apart. Needle pricks could not be felt from the middle of the femur downwards. The interesting points in this case are the enormous size, the luxation of the hip joint, and the apparent disappearance or absorption of the bony structure of the lower part of the limb. The case reminded him very much of one described by Katholicky and presented to us two years ago, and which he diagnosed as lymphangioma cavernosum.

The treatment of this case seems to point to the enucleation of some part of the morbid mass, although the greatly impoverished condition of the patient imposes great risk on the operator.

OTOGENER FACIAL PARALYSIS.

Alexander showed a case of facial paralysis from Politzer's clinic which he had successfully improved by anastomosis with the facial accessorius. The functional results have been excellent.

LYMPH-ANGIOMA.

Leischner showed a preparation taken from an excised portion of a similar case described above by Eiselsberg. The subcutaneous tissue was filled with cysts and caverns sharply defined as lymphangioma, but there were no symptoms of chyle or chylous vessels present.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

GIRGENTI INEBRIATE REFORMATORY, GLASGOW.—During the fifth year of the working of this institution terminating on December 31st, 1905, twenty-five patients were admitted, making a total of 113 from the commencement, the average daily number of inmates being 31.3. During the year 18 patients were allowed out on licence under the care of suitable guardians; of these 6 relapsed, one absconded, 4 returned to the Reformatory having given complete satisfaction to their guardians, the sentences of 4 expired while they were on licence, while three continue on licence. During the year 14 inmates escaped or attempted to do so. One escaped five times; two, 3 times; four, twice; and seven once. One of these patients is still at large, while two have been transferred to Perth. The large number of escapes is partially accounted for by the fact that the Girgenti Reformatory is not a walled-in Institution. Seventeen out of the 29 inmates discharged during 1904 have since the expiry of their sentences been convicted of drunkenness, and a similar fate has befallen 6 out of 16 inmates discharged during 1905. Dr. John Cunningham, the medical officer, in his report on the working of the reformatory, states that it is still impossible to form any decided opinion regarding hereditary alcoholism among the inmates, but most admit having had a drunken father. Probably not the disease, but a tendency to it, is inherited which shows itself in other neuroses as well as inebriety. The largest number of the patients belong to the lowest stratum, and are practically pauper inebriates. During 1902 Dr. Cunningham made exhaustive inquiry about so-called "cures" for alcoholism by secret drug treatment without being able to recommend any of them for use in the Home. Last year, on the recommendation of a medical gentleman, who claimed most wonderful results, he tried the administration of sulphate of atropine, grs. 1.00 daily, and a mixture containing quinine, sodium, ammonium, and aloin. The treatment was tried on 22 inmates for a period of one month; they suffered more or less from gastro-intestinal symptoms for a few days, but thereafter the medicine

acted as a tonic and a more liberal diet was permitted as a consequence of the increased appetite. The patients were not specially selected in any way. The following is the result of the experiment. Three patients, who, when previously licensed out had relapsed, have remained abstainers, 11 patients have returned to their former habits, and 8 patients have still to be liberated on licence before any judgment can be formed as to the effect of the treatment. Dealing with the "failures when liberated," Dr. Cunningham's opinion is that the hopeless cases, in whom there is mental enfeeblement, should not be liberated, but should be transferred to the wards of a poor-house or kept constantly under supervision by boarding them out in the country as is done in the case of harmless female lunatics.

EDINBURGH ROYAL INFIRMARY.—The managers have appointed Drs. Carnegie Dickson and Henry Wade assistant pathologists in place of Drs. Stuart McDonald and Lyon, resigned. Dr. W. T. Ritchie has been appointed clinical pathologist to the institution. Dr. A. H. F. Barbour has been appointed gynaecologist *vice* Dr. D. Benj. Hart, resigned.

BELFAST.

SAMARITAN HOSPITAL.—At the annual meeting of the Samaritan Hospital, held last week, the resignation of Dr. J. St. Clair Boyd on the ground of ill-health was accepted, and Dr. G. A. Hicks was appointed in his place. There was no contested election, as Dr. Hicks has been for some time Dr. John Campbell's assistant, and as such has constantly helped him at his hospital work, and now by this arrangement becomes his colleague.

NURSES FOR THE SICK POOR.—The annual meeting of this most excellent society was held in Belfast last week, and the report of another year's work presented. There are now ten nurses, who nursed 1,136 cases, including 202 of consumption and 65 of cancer, and paid 33,542 visits during the year. Professor Byers, in speaking at the meeting, dwelt particularly on the educative effects of the nurses' visits in the homes of the poor, which he regarded as very important.

ULSTER EYE, EAR, AND THROAT HOSPITAL.—The annual meeting of this hospital was held last week, and the hospital re-opened after general cleansing and renovating. The medical report showed an active year's work, there having been over 2,500 extern patients and 329 intern.

BELFAST WATER SUPPLY.—In consequence of various rumours as to the contamination of the water reservoir at Stoneyford, near Belfast, a statement on the subject was made at a meeting of the Water Commissioners last week. It seems that no cases of typhoid exist in the catchment area, and the last quarterly report of Professor Frankland gave the water an excellent character. Arrangements have been made with the dispensary doctor to notify any case of typhoid or other infectious disease occurring in the neighbourhood to the Commissioners, so that prompt steps may be taken to prevent contamination of the water, and about £50,000 has been spent in the last few years to give them more complete control over the land round the reservoir.

LETTERS TO THE EDITOR.

PROPOSED UNION OF MEDICAL SOCIETIES—A DISCLAIMER.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I trust that you will have the goodness to allow me the courtesy of your columns to make a personal explanation.

At the recent annual meeting of the Royal Medical and Chirurgical Society, *apropos* of the question whether the premises at 20, Hanover Square would be suitable for the proposed amalgamated society, I understand that one of the Fellows present stated that I had been consulted as to the condition of the

premises, and that I had reported "that the building would require pulling down and re-building in about fifty years."

I desire to say that there is not the slightest foundation or justification for such a statement. I have not discussed the matter with any but the Officers of the Society, and had I been asked for my opinion as to the probable duration of the present building, I should have stated emphatically that it was, in my opinion, as likely to stand for another hundred years as any building of its age in London, and I have not the slightest doubt that it will remain a good and useful building for even a longer period if kept in proper repair.

I am, Sir, yours truly,

JOHN BELCHER, A.R.A.,
President R.I.B.A.

20, Hanover Square, W., March 8th, 1906.

A MEDICAL VIEW OF THE NATIVE LABOUR IN THE TRANSVAAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is stated in recent news from London that one of the Transvaal companies has been compelled to shut down because there was no prospect of finding an adequate number of natives to work the mines.

An explanation of this and other similar news coming from the Transvaal mines for some time back, may be furnished by the corresponding medical news in the Colonial journals, namely, that the natives soon become affected by blindness, so as to unfit them for any work below, where semi-darkness prevails. After some treatment in the local hospitals for the alleviation of the malady they get temporarily better, but the blindness recurs as soon as they return to work in the mine below ground.

It may be conjectured that the air in some galleries of the mines is fouled by the fumes from the gold and other ores, so it requires to be thoroughly ventilated by adequate machinery to fit it for the respiration of the natives of the country. Presumably the Chinamen now being employed are less affected by the foul air, and therefore have, in due course, supplanted the natives of the country in this class of work below ground in consequence, as the latter are naturally habituated to crop and field work.

I am, Sir, yours truly,

A MEDICAL TRAVELLER.

THE TRIBUNE AND QUACK ADVERTISEMENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—If Mr. Sparkhall, the manager of the *Tribune*, wishes to realise at first hand the iniquity of the quack medicine trade he can easily do so in the out-patient department of any great hospital. I well recollect the first case that attracted my attention to this subject. It was a woman who applied to the late Mr. Teevan, at the West London Hospital, with cancer of the breast. The disease was quite beyond the scope of surgery, and had progressed during two years into that state whilst the wretched patient had relied upon a "heal all" ointment, then most extensively advertised, and which brought its infamous proprietor a vast fortune. Besides cases like this, all sorts of serious diseases made chronic or incurable through reliance upon the false pretences of the quack, a vast number of victims of quackery of other sorts will be easily discoverable. Not the least sad among them are the poor infants, systematically drugged by simple, ignorant mothers with soothing syrups of one kind or another. An inquest on an infant dead from this cause is reported on page 201 of the issue of Feb. 21. Those that escape with their lives are often made rickety cripples from this cause alone. A vast proportion of cases of diseases of the rectum are due solely to the prolonged use of quack pills, nearly all of which, whatever their pretensions, are compounded solely of coarse drastic purgatives. It is only a short time ago that a minute analysis was made of a variety of extensively advertised

"cures" for fits and epilepsy. They were all found to be crude frauds, and whilst they were retailed at prices from several to many shillings a packet, it was proved that in no case did their intrinsic value exceed a few pence. All these facts are easily to be verified by any newspaper manager who cares to take the trouble.

I am, Sir, yours truly,

G. P. No. 2.

February 21st, 1906.

THE OPSONIC INDEX.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—Your correspondent "Cunctator," undoubtedly touches on a practical disadvantage in the application of opsonic estimation to the control of vaccine treatment, when he mentions that the process is highly technical. It does not, on that account, deserve the condemnation he metes out to it. Similar objections were raised, to mention only one or two instances, to Listerism, when first introduced, and to the Widal test for typhoid fever. I do not know whether ten guineas is, as "Cunctator" states, a usual fee for a single estimation, but I know that one of the clinical laboratories lists it at a guinea and a half, and there are many competent pathologists willing to make observations for slightly higher fees. When "Cunctator" states that we gain nothing by knowledge of the opsonic index beyond what we might learn by simple clinical observation, he shows, I fear, a somewhat slight study of the subject. Professor Wright has made it clear that clinical observation gives us no indication of the suitability of the dose until the damage has been done, whereas opsonic estimation allows a very accurate control of the dosage of vaccines. The success of the method both in his own hands and in those of his pupils is sufficient justification. There are doubtless many points open to criticism in Professor Wright's arguments. The criticism, however, should be intelligent and instructed. Sneers and jibes, such as those with which "Cunctator" closes his letter, do not help the settlement of any point in science.

I am, Sir, yours truly,

CRITICUS.

REVIEWS OF BOOKS.

STEWART'S PHYSIOLOGY. (a)

FIVE editions and three reprints in the course of just over nine years ought to satisfy any author that he has not written in vain. And this is the record of Professor Stewart's *Manual of Physiology*, a new edition of which lies before us. A good deal of re-writing and the addition of a considerable amount of new matter have been necessitated by recent work and more extended experience, but by the adoption of a smaller type this manual remains a manual. To those who are unacquainted with it, it may be said that a distinctive—and a very valuable—feature of Professor Stewart's *Physiology* is that theoretical disquisition and practical exercises are treated as integral parts of instruction, and the book is so arranged that laboratory work illustrating the principles dealt with in the text is described at the end of each chapter. It is thus intended that the book shall combine the functions of a treatise and a practical handbook, and the course is so mapped out that each shall proceed *pari passu* with the other. The author's experience as a teacher, examiner, and investigator on both sides of the Atlantic have given him a wide knowledge of his subject in relation to students' requirements, and we are not therefore surprised at the gratifying success which has attended his attempt to produce a systematic work. The more the book is studied the easier

(a) "A Manual of Physiology. With Practical Exercises." By G. N. Stewart, M.A., M.D., D.Sc., D.P.H., Professor of Physiology in the University of Chicago. Coloured Plates and nearly 400 other illustrations. Fifth Edition. Demy 8vo. Price 16s. net. London: Baillière, Tindall and Cox, 1906.

will it be to see why it is so much appreciated. The style is free, but dignified; the thought clear and lucidly expressed; and the teaching as definite as it is possible for physiological teaching to be. It is marvellous, indeed, how Professor Stewart has contrived in less than 900 pages of text, a good deal of which space is occupied by illustrations, to include all the essentials of a physiological course without any appearance of "cram." The author is evidently in love with his subject and he succeeds in imparting to his readers the feeling that physiology is the science of living tissues, and not a conglomeration of microscopic preparations and electrical apparatus. He has evidently taken great pains with the revision of the text, and it seems to us as accurate in letter as it is in fact. We can cordially recommend the book to the notice of teachers and demonstrators, feeling sure that they and their students could have no better guide.

THE EDINBURGH MEDICAL JOURNAL. (a)

THE half-yearly volume of this journal has just reached us in its familiar form. No lengthy review of it is necessary, as some of the individual numbers of which it is composed have already been noted in our columns, and abstracts of two or three important papers contained within it have been published in our "Weekly Summary." While not containing any very epochal papers, it is still characterised by the general high character of the original articles which have been contributed to it, many being of more than passing interest, and constituting valuable additions to the literature of the subjects with which they deal. Among these may be mentioned the report by Dawson on his investigations into "The Condition of the Blood after Operation and Fracture." The investigation was carried out in a most thorough manner, and led to the following among other, conclusions:—(1) After every operation the leucocytes increase in number, independently of the number of red blood corpuscles. This increase reaches a maximum within a few hours, and then slowly disappears in the course of the next couple of days. (2) The leucocytosis is principally of neutrophile leucocytes, but the hyaline cells also take part in it. The lymphocytes and eosinophile cells, on the other hand, show diminution in both relative and absolute numbers. (3) The leucocytosis is apparently independent of (a) the amount of hæmorrhage; (b) the severity of the operation; (c) the anæsthetic employed; (d) the preparation of the patient. (4) A failure in the normal decrease of leucocytosis after a couple of days is to be regarded as pointing to the existence of some septic complication. Another most valuable paper, or rather monograph, is that on "Hypertrophic Pulmonary Osteo-arthritis," by Dr. Donald Hall. Two new cases are reported, in one of which death occurred from sarcoma of the lung, and in which a full *post-mortem* examination was obtained; a very complete summary of the previous literature is given, and the paper is illustrated by some excellent photographs and skiagraphs, and a bibliography is added. Dr. Gibson's paper on Bradycardia is also well worth reading, containing as it does the results of the writer's matured experience, and last, but not least, must be mentioned Barry Pain's "Treatment of Facial Palsy." It is, we imagine, this writer's first communication on a medical subject, but we hope that it will not be his last.

THE TREATMENT OF SYPHILIS. (b)

THIS little book, which is evidently the outcome of the author's great experience gained in many lands and climates (as mentioned in the preface by Surgeon-General Gellway), should be of great interest and use to all naval and military surgeons; it strenuously advocates the intra-muscular treatment, and this is undoubtedly one easily carried out on patients who are under discipline and who come daily under the personal

(a) "The Edinburgh Medical Journal," Vol. xviii, 1906. Edinburgh and London: Young J. Pentland.

(b) "The Treatment of Syphilis." By F. J. Lambkin, Lt.-Col. R.A.M.C. Pp. 60. London Baillière, Tindall and Cox. Price 3s.

observation of the medical attendant. Medical men, however, will read with surprise the author's dictum that after mercury had been administered by the mouth for, say, a couple of months, it began *in most cases* (the italics are ours) to disagree with the patient, the digestive system becoming upset and impaired and the general health falling off in consequence"; also "With regard to diet, among the advantages of the external methods is that under them it is luckily not necessary to curtail diet *in the same way as it is with the internal*" (the italics are ours). On the other hand, Col. Lambkin's arguments in favour of the intramuscular treatment are sound, and his words must be received with due consideration. The treatment might certainly be carried on with advantage in the Navy and Army and amongst those of the leisured and wealthy classes who would face the discomfort and risks (however small) of a surgical operation (however trivial) twice a week during at least a year.

PUBLIC HEALTH LABORATORY WORK. (a)

THE purpose of this well-printed and handsome manual is to provide an "outline of the more important matters discussed at practical examinations in Sanitary Science." In fact, the title and the purpose described above are somewhat wider than the actual scope of the work. It is a compilation of some of the principal methods of laboratory examination of water (90 pages) sewage effluents (3 pages), soils (3 pages), air (28 pages), various foods and disinfectants; with an appendix of the preparation of some standard solutions and of the general chemical reactions of common metals and acids whether important for the public health laboratory or other requirements (54 pages). The descriptions are admirably neat and clear, though not always as detailed as would be desirable; and while necessarily having no pretensions to originality the book will leave the student who works through it with a knowledge probably sufficient to get through such an examination as the author contemplates in the special branches of the subject which come into the book. It must be confessed, however, as will be seen by the analysis of the space devoted to the subjects named above, that the author's sense of the prospective importance of the various subjects is open to question. It is difficult to imagine a student coming away from a laboratory course conducted in accordance with Dr. Sommerville's chapters with a practical grip of proportion between the various parts of the science. For the most part the methods are not only well described but well selected; we noticed, however, occasional discrepancies between the text book and practical experience which should be rectified in another edition. The copper zinc couple, for instance, cannot be used for sewage with even as much accuracy as the phenol-sulphonic acid method, which for water is much less accurate. If the reader is presumed to be so placed in chemistry as to have a use for the appendix on the reaction of metals and bases, it is scarcely reasonable for his study of sewage to be complete in three pages and meat in eight; nor would he be likely to have in advance the familiarity with bacteriological method which is postulated by the author in dealing with the biological examination of water. These criticisms notwithstanding, we can strongly recommend the work to all aspirants for the D.P.H., of which the foundation of its pages is the practical course at King's College, London.

ORGANOTHERAPY. (b)

ORGANOTHERAPY is no new means of combatting disease. The administration of animal tissue for the prevention and alleviation of human maladies is a practice the origin of which is lost in the ruts of pre-historic

(a) "Practical Sanitary Science: A Handbook for the Public Health Laboratory." By David Sommerville, B.A., M.D., D.P.H. (Camb.), M.R.C.P. (Lon.), London: Baillière, Tindall and Cox, 1906. With 92 plates and other illustrations. Price 10s. 6d.

(b) "Organotherapy or Treatment by Means of Preparations of Various Organs." By H. Batty Shaw, M.D., F.R.C.P., Lecturer on Therapeutics, University College, London, &c. London: Cassell and Co. Limited, 1905. Price 6s.

times. Modern organotherapy may be said to date from 1889, when Brown-Séquard brought the question of internal secretion into prominence by his advocacy of the use of testicular fluid as a means of staving off the oncoming of old age. Later the great benefits derived from thyroid administration, and, more recently, the remarkable service rendered by suprarenal abstract, have quickened interest and stimulated research into all matters touching organotherapy. Dr. Batty Shaw has therefore accomplished a real service in furnishing so admirable an epitome as is offered in this compact, concise and yet comprehensive manual. The author claims that his book is "an attempt to place before the reader a short account of the physiology, &c., of the glands of the body with special reference to internal secretion, and to supply a review of the practical applications in disease of the derivatives of various organs." And he has attained his end. The work is divided into five sections dealing respectively with the thyroid and para-thyroid glands, the adrenals, the alimentary tract, including pancreas and liver. Genito-urinary organs, and such other organs and tissues as the pituitary body, the thymus, the spleen, bone marrow and lymphatic glands. Much painstaking care has been taken, and extensive bibliographical research is evidenced on almost every page. The work is an excellent epitome and well suited to the needs of the busy but conscientious practitioner, eager to keep himself abreast with the best results of recent medical research. But in spite of its many excellencies the work is disappointing. It lacks the force and vigour of personality. The author never ventures to express his own views, and we have failed to discover any reference to personal researches or original observations. Nowhere in the volume can we find the personal pronoun, and such self-suppression tends to make a work lack in suggestion and powers of service. What is presented is so excellent that we could have wished that the author had allowed us the benefit of his own opinions, and the guidance of his own clinical observations. But this lack we trust may be rectified in the next edition. The general get-up of the volume is thoroughly good and quite in accordance with what we expect from the publishers.

WOOD ON THERAPEUTICS.(a)

We can quite understand how it is that Dr. Wood's large work has reached its twelfth edition in America, as it appears to us to be clearly expressed, written in a scientific spirit, and almost comprehensive. Of necessity, however, an American, or any other foreign work on "therapeutics," is at a serious disadvantage in this country, owing to the non-correspondence of the pharmacopœia of the two countries. Dr. Wood's work is divided into two main parts. Part I. deals with "Remedies, remedial measures, and remedial methods which are not drugs," and under this heading is grouped a large amount of information regarding foods, caloric, electricity, and the treatment of "systemic states." Part II., which constitutes the major part of the book, deals with drugs. The author's classification of the latter is simple. He first constitutes two main groups: "Systemic remedies" and "extraneous remedies." The systemic remedies are divided again into "general remedies" and "local remedies," and the former of these is subdivided into "nervines," "cardiants," and "nutrients." One naturally shudders at the idea of a work on therapeutics written in Americanese, since the terminology of the subject is capable of affording such evident opportunities to philological reformers, and lest the three last-mentioned terms should make the reader think that Dr. Wood's work is so written, we hasten to reassure him. Throughout the book is written in the English language, a fact on which we congratulate both author and publisher. We think we can perhaps best show the opinion we have

(a) "Therapeutics: its Principles and Practice." By Horatio C. Wood, M.D., LL.D., Professor of Materia Medica in the University of Pennsylvania. Twelfth edition, revised and adapted to the eighth edition of the United States Pharmacopœia. Philadelphia and London: Lippincott and Co. 1905.

formed of Mr. Wood's work by saying that in spite of the fact of the difference in the English and American pharmacopœia, we can recommend it to English readers with a certainty that they will derive extreme profit from a perusal of it.

HARROGATE—WATERS, BATHS, AND CLIMATE.(a)

This book follows much the same lines as others of its class. It describes the various waters and baths to be obtained at Harrogate, and gives a sketch of the climate and situation of the Spa. Some physiological and clinical material is supplied to aid in the proper comprehension of the advantages offered by residence at Harrogate, and the diseases that may and may not be expected to be assuaged are detailed. Analyses of the various waters are given, and we learn that sodium chloride appears to be the most prominent ingredient. Sulphur and iron are present in some. Luxurious baths of all kinds are installed, and the amenities of spa-life are well catered for. We cannot, then, but wonder why practitioners continue to send so many of the patients to the Jordans of Germany, when Abanas and Pharpars of such elegance and therapeutic efficiency are within a few hours' journey of the metropolis.

LITERARY NOTES.

THE "St. Thomas's Hospital Reports," for 1904 (New Series, Vol. XXXIII.), edited by Dr. Hawkins and Mr. Battle, is as carefully prepared and exhaustive as any of its predecessors. The statistical tables are, indeed, marvels of condensed information, and there are added concise notes on all medical and surgical cases of special interest. Messrs. Cuthbert Wallace and Percy Sargent contribute a useful critique on Appendicitis, based on the last 1075 cases observed in St. Thomas's Hospital. Messrs. Ered Corner and H. Pinches discuss Torsion of the Omentum with a *résumé* of all recorded cases. There is a very interesting and sympathetic obituary notice of the late Sir John Simon, which pictures a side of his character but little known—that of hospital surgeon. The volume of Reports is well worthy of the great hospital from which it emanates. ***

DR. THOS. JOHNSTONE (translator of Professor Kraepelin's classic work on "Clinical Psychiatry" voices an opinion in his paper on "Dementia Præcox" which deserves to become axiomatic, that "age is a relative term; a man is as old as his bloodvessels, and lives till his heart batters him to pieces." ***

THE fifth edition of Professor G. N. Stewart's "Manual of Physiology" is now free of the press. It is an ideal text-book for students, and we hope shortly to refer to the many alterations and additions made by the author in this new edition. ***

We are glad to note that Dr. Bianchi's great work a "Text-Book of Psychiatry" has just been brought within the compass of English-speaking physicians, by Dr. J. H. Macdonald, physician to the Govan Asylum, who has translated it at the author's request. Bianchi, whose name is held in honour by alienists in all parts of the world, is now Professor of Clinical Psychiatry in the Royal University of Naples and Minister of Public Instruction in Italy.

Society of Apothecaries of London.

THE following candidates having passed the necessary examinations, have received the L.S.A. Diploma of the Society, entitling them to practise medicine, surgery, and midwifery:—W. G. H. Cable, M. O. Dollie, C. W. Gibson, J. P. B. Snell, R. J. S. Verity, and M. C. Vivian.

(a) "The Physiology and Therapeutics of Harrogate Waters, Baths and Climate, applied to the Treatment of Chronic Disease." By William Bain, M.D., M.R.C.P., and Wilfrid Edgecombe, M.D., F.R.C.S. 7s. 6d. net. Longmans, Green and Co., London, New York and Bombay. 1905.

NEW BOOKS AND NEW EDITIONS.

THE following have been received since the publication of our last list:—

- SIDNEY APPLETON.** (London.)
Differential Diagnosis and Treatment of Disease. By Augustus Cailla, M.D. Illustrated. Pp. 867. Price 25s. net.
- BALLERE, TINDALL AND COX.** (London.)
Gynaecological Diagnosis: A Manual for Students and Practitioners. By Arthur E. Giles, M.D., B.Sc., &c. Illustrated. Pp. 212. Price 7s. 6d. net.
- The Treatment of Gonorrhoea in the Male. By C. Leedham-Green, M.B., F.R.C.S. Pp. 152, with 36 figs. Price 5s. net.
- The King's Coroner. Being the Practice and Procedure in his Judicial and Ministerial Capacities. By R. Henslowe Wellington. Vol. 2 (complete in itself). Pp. 148. Price 7s. 6d. net.
- Laboratory Manual of Physiology. By Frederick C. Busch, B.S., M.D. Illustrated. Pp. 206. Price 6s. net.
- Examination Questions for the Diploma of Public Health. By Hugh R. Jones, M.A., M.D., D.P.H. Pp. 100. Price 2s. 6d. net.
- J. F. BERGMANN.** (Wiesbaden.)
Leitfaden Studium der Experimentellen Biologie der Wassertiere. By J. v. Uexküll.
- Die Verletzungen der Nase und deren Nebenhöhlen. By F. Kopke.
- Über Missbildungen der Menschlichen Ghedmassen (Nene Folge). By Prof. Dr. F. Klaussner.
- Über das psychische Verhalten des Arztes und Patienten vor, bei und nach der operation. By Professor Dr. F. Klaussner.
- J. & A. CHURCHILL.** (London.)
Clinical Applied Anatomy; or, The Anatomy of Medicine and Surgery. By Charles R. Box, M.D., &c., and W. McAdam Eccles, M.S. F.R.C.S. Illustrated. Pp. 471. Price 12s. 6d. net.
- Essentials of Surface Anatomy. By Chas. R. Whittaker, L.R.C.S. L.R.C.P., &c. Pp. 40. Price 2s. 6d. net.
- Chavasse's Advice to a Mother. Sixteenth Edition, revised and largely re-written. By Thomas Dewich Lister, M.D. Lond. Pp. 454. Price 2s. 6d.
- CORNISH BROS., LTD.** (Birmingham.)
Diseases of the Rectum. By F. Victor Milward, M.B., B.C., &c. Pp. 193. Price 5s. net.
- ARTHUR C. FIFIELD.** (London.)
Curdled Milk: A Natural Key to Health and Long Life. By Dr. A. Montenius. Translated by Fredk. Rottwell, B.A. Pp. 59. Price 6d. net.
- WILLIAM GREEN AND SONS.** (London.)
The Cleansing, Disinfection, and Protection of the Hands. By Dr. Carl S. Haeger. Translated by Charles Heron Watson, M.A., M.B., &c. Illustrated. Pp. 218. Price 6s. net.
- T. C. AND E. C. JACK.** (Edinburgh.)
The Edinburgh Stereoscopic Atlas of Anatomy. Edited by David Waterston, M.A., M.D., &c. Section 4, containing 50 Stereographs. Price 25s. net.
- RICHARD J. JAMES.** (London.)
The Alcohol Problem in its Biological Aspect. By T. N. Kelnack, M.D., M.R.C.P. Pp. 143. Price 2s.
- H. K. LEWIS.** (London.)
The Liverpool Medico-Chirurgical Journal. Vol. XXV. 1905. Pp. 414. Price 7s.
- LONGMANS, GREEN AND CO.** (London.)
The Health of Our Children in the Colonies. By Dr. Lilian Austin Robinson. Pp. 182. Price 2s. 6d. net.
- MACMILLAN AND CO., LTD.** (London.)
Chemistry of the Proteids. By Gustav Mann, M.D. Ed., B.Sc. Oxon. Pp. 606. Price 15s. net.
- On Professional Education with special reference to Medicine. By T. Clifford Allbutt, M.A., M.D., &c., &c. Pp. 60. Price 2s. net.
- OLIVER AND BOYD.** (Edinburgh.)
Notes on Surgery for Nurses. By Joseph Bell, M.D., F.R.C.S. Ed. Sixth Edition, thoroughly revised. Pp. 187. Price 2s. 6d.
- REBMAN, LTD.** (London.)
On the Relations of Diseases of the Skin to Internal Disorders. By L. Duncan Bulkley, A.M., M.D. Pp. 175. Price 6s. 6d. net.
- W. B. SAUNDERS CO.** (Philadelphia.)
Reference Handbook of the Diseases of Children. By Prof. Dr. Ferdinand Fruhwald. Edited by Thompson S. Westcott, M.D. Illustrated. Pp. 533. Cloth, 18s. net.
- The Operating Room and the Patient. By Russell S. Fowler, M.D. Illustrated. Pp. 172. Price 10s. net.
- JOHN WRIGHT AND CO.** (Bristol.)
Lectures to Teachers on the Prevention of Infectious Diseases. By Wm. Berry, F.R.C.S.I. Pp. 64. Price 6d. net.
- First Aid to the Injured and Sick. By F. J. Warwick, B.A., M.B. Cantab., &c., &c., and A. C. Tunstall, M.D., F.R.C.S. Ed. Fourth Edition. Pp. 242. Price 1s. net.

OBITUARY.

JOHN CHESTNUTT, B.A., L.R.C.S. & P. ED., V.D.

THE death occurred at Matlock on February 4th, of Mr. John Chestnutt, of Howden, Yorkshire, at the age of fifty-five years. Mr. Chestnutt was a native of Ireland, being son of the late Rev. Wm. Chestnutt, of Tralee. He had a distinguished college career, being senior scholar, exhibitioner and prizeman. He graduated B. A. with honours at the Queen's University obtained the licence of the Royal Colleges of Physicians and Surgeons, Edinburgh. His College course was at Cork, Leeds, and Edinburgh. He settled at some twenty-five years ago. He was

medical officer to the district workhouse to the post-office staff, and various clubs, and enjoyed an extensive practice, being extremely popular with all classes. He was a member of the St. John's Ambulance Association, and was for many years Lecturer and Examiner through his efforts also the Howden Nursing Association was formed for work among the poor. An ardent volunteer, he retired a few years ago with the rank of Major and was awarded the volunteer decoration for long and good service; he rejoined in the medical department as Surgeon-Lieut. and was gazetted surgeon Major a week before his death. He was a Fellow of the British Gynaecological Society and member of the British Medical Association, of the Royal Society of Antiquaries, Ireland, and Archæological Society of Yorkshire.

THOMAS EDMONSTONE CHARLES, M.D., LL.D. ED. F.R.C.P. LOND.

WE regret to announce the death of Surgeon-General Thomas Edmondstone Charles, M.D., late of the Indian Medical Service and an honorary physician to the King, on March 2nd, at Flushing, Falmouth, in his seventy-second year. He was born in Calcutta and educated in Edinburgh; an M.D. of Edinburgh in 1885, and also studied in Paris and Berlin. In 1856 he entered the Bengal Medical Service, and went through the Indian Mutiny. For some time he was Superintendent General of Vaccination and Professor of Midwifery in the Medical College at Calcutta. He retired from the Indian Medical Service in June, 1883, as a deputy-surgeon-general, and since that date had been an honorary physician to her late Majesty and the King. For several years afterwards he practised with great success at Cannes. In 1895 he received the degree of LL.D. from his university. He has left behind the bright example of an honourable and strenuous career.

JOHN DAVIES JAMES, M.R.C.S. ENG., J.P., D.L.

DR. JOHN DAVIES JAMES, of The Grove, Blackwood, died on Sunday at the age of seventy-two. He was the second son of Mr. Edmund James, of Tynemoyd. He was medically educated at St. Bartholomew's Hospital, and became a member of the Royal College of Surgeons in 1857. In the same year he took up his residence at The Grove, Blackwood. After achieving a reputation as a skilful practitioner, Dr. James retired in 1890 from the profession, to which for over thirty years he had devoted himself. He was placed on the commission of the peace in 1869. In 1871 he was elected a member of the first Bedwelley School Board. Dr. James was made Alderman in November 1903. In 1897 he became chairman of the Bedwelley Division of county justices, and performed the functions of the office with an ability that secured the approval of his colleagues and the esteem of the general public. The position of deputy-lieutenant for the county was one that when conferred upon Dr. James gave lively satisfaction to a host of friends and well-wishers. In politics he was a Conservative, and in religion a Churchman.

The Royal Waterloo Hospital.

THE energetic authorities of the Royal Waterloo Hospital for Children and Women have issued a preliminary prospectus of an enterprise on a very large scale, which is to take place at the Crystal Palace, Sydenham, in June next, the proceeds being devoted to the special appeal fund of the hospital referred to. The entertainment will consist of a reproduction of the Nice Carnival, with processions of decorated cars, battle of flowers, costume ball, etc. The entire fêtes are being organised by E. Douglas White, and several prominent members of the theatrical profession have kindly offered their services.

H.R.H. THE DUCHESS OF CONNAUGHT has consented to inaugurate the Elizabethan fair and fête which is to be held in London next May in aid of the King's College Hospital Removal Fund. In connection with the same Fund the directors of Messrs. Harrods (Limited) have made a donation of 2,000 guineas.

MEDICAL NEWS IN BRIEF.

Crier and Wife v. Hope and Currie.

THE hearing of this case, on the 8th inst., in the King's Bench was concluded. The plaintiffs, Mr. and Mrs. Crier, sued a firm of medical practitioners, practising at Hanwell and West Ealing, to recover damages for alleged negligence on the part of Dr. Currie, whereby he was said to have conveyed scarlet fever infection to the female plaintiff. The defendants denied liability. Mr. Justice A. T. Lawrence, in summing up to the jury, said the plaintiffs were not entitled to demand the highest skill in their medical men, but only the reasonable skill and care of the ordinary doctor. It had been said that if a doctor went from an infectious case to a case of confinement, even though he took precautions, he did it at his own risk. He thought for himself that that was putting the case too high. Dr. Currie was told that the confinement was expected on November 15th, but, as they knew, the fixing of these dates was always somewhat uncertain. On the 14th, he saw the little girl at Mrs. Miller's suffering from scarlatina, and the next day he visited the boy, who was also infected. It was said that, knowing that the confinement was expected on the 15th, he ought not to have made these visits; but it seemed to him that in the case of a general practitioner it would be rather straining things to lay down such a rule. To his mind the whole case turned on the question of the precautions he took before seeing Mrs. Crier. Then it was said he should have sent another doctor; and this raised a more difficult question. Was it negligent not to do so? That depended upon whether he thought the precautions he had taken were adequate or not. If he thought they were not he should have sent for another doctor, without doubt. That brought him to the chief question: Were the precautions those which a reasonably skilful doctor would take? On this the evidence of the doctors for the plaintiffs and defendants was divergent. [His Lordship described the precautions as detailed by Dr. Currie.] He had walked to visit a patient, and then half-a-mile to a cabstand. The plaintiffs contended that this was not sufficient, that all the clothes should have been changed. The defendants' reply was that this was a counsel of perfection not practicable in actual practice. Where an epidemic was raging it would be impossible for a medical man to take a bath and change his clothes after visiting every infectious case. As to what took place subsequently, it was alleged that Dr. Currie had made untrue statements, and he had admitted that he had not been altogether candid. If they thought that this showed that he knew he had been guilty of a want of care these statements were important, otherwise they were less important. Dr. Currie had frankly admitted that he had intended to mislead Mr. Crier in speaking of his attendance on scarlatina cases. The jury retired to consider their verdict at 12.25. They returned into court at 1.45, and the foreman said that they all agreed that Dr. Currie had taken the usual precautions, and found a verdict for the defendants. The learned judge gave judgment for the defendants on the question of negligence, with costs. Stay of execution was granted on the usual terms.

Royal University of Ireland.

At a meeting of the Senate on Wednesday, March 7th, 1906, a letter was read from the Rt. Hon. the Earl of Meath, K.P., intimating that for the reasons stated therein, he had placed his resignation as Chancellor of the University in the hands of his Excellency the Lord Lieutenant. The following resolution was unanimously adopted:—"The Senate have heard with great regret that the Earl of Meath has resigned the office of Chancellor of the University, and they take this opportunity of expressing their high sense of the

whole-hearted devotion with which he applied himself during the period for which he held office, to the work of the University, and to the promotion of its interests."

The following resolution, to consider which the meeting was specially convened, was proposed by the Most Rev. Dr. O'Dwyer, Bishop of Limerick, seconded by Rev. Dr. Hamilton, and adopted:—"That the Report of the Royal Commission in its animadversions on this University as an examining body, indicated truly the essential defect in its constitution, and we believe that its reform in this respect, so as to make it a technical university with colleges adequately constituted and brought into organic connection with it, is a matter of urgent need both for the University itself and for the interests of higher education in the country." And it was ordered that copies be sent to his Excellency the Lord Lieutenant, the Prime Minister, and the Chief Secretary.

Irish Medical Schools' and Graduates' Association.

THE Annual Festival Dinner of the Irish Medical Schools and Graduates' Association will be held on Saturday next, March 17th (St. Patrick's Day), at 7.30 p.m., in the Grand Hall, Hotel Cecil, Strand. The guest of the Association will be General Sir John French. Applications for tickets from members to be sent to E. Canny Ryall (hon. sec.), 85, Harley Street, London. W.

University of London.

THE following candidates have passed the Intermediate Examination in Medicine:—Eileen Elizabeth Allen, Malcolm Edward Ball, Frederick Michael Bishop, Herbert Orpe Brookhouse, John Philip Buckley, Arthur Laurence Candler, Bernard Arthur Cheadle, Joseph Harry Clarke, Ernest Neville Cook, Ethel Constance Cousins, Lawrence Croft, Aston Ridley Dale, Arthur Davies, Trevor Berwyn Davies, Newton Charles Davis, Canut Deunzter, Ethel Adelaide Douglas, Evan Parry Evans, Thomas Evans, William Vincent Field, Josephine E. L. Griffiths, Ethel Margaret Eades Hall, George Blenkhorn Harland, William Roberts Harris, Fredk. Whewell Hogarth, Sidney Ernest Holder, Kenneth Hill Hole, Habibmia I. Janmahomed, David Judah, Arthur Norman Leeming, Alfred Everard Lees, Herbert Cubitt Lucey, Edmund Garvin Mack, Claude Herbert Marshall, Edward Kenneth Martin, John Birch Martin, Howard Edwd. Hall Mitchell, Max H. Edwd. R. Montesole, Mark Alleyne Nicholson, Owen Brynrog Parry, Mary Elizabeth Parsons, Eustace M. Parsons-Smith, Philip Seymour Price, Thomas Edwin Pryce, Douglas Reynolds, Rowland Waters Rix, Mabel Russell, Arthur Fredk. Sanderson, Harold Willis Scawin, John Edward Scudamore, Frank Standish, Tom Stansfield, Horace Elliot R. Stephens, Kenneth Henry Stokes, Hugh Stott, Gravenor Robert Strong, Geoffrey Viner, Dora Muriel Watney, Lilian Enid Watney, Richard Tudor Williams.

THE Twenty-third Annual Congress of the Royal Sanitary Institute will be held at Bristol, July 9th to 14th, 1906, under the presidency of the Rt. Hon. Sir Edward Fry, D.C.L., F.R.S. Her Grace the Duchess of Beaufort will preside over the Ladies' Conference, and the following will act as presidents:—Section I., Sanitary Science and Preventive Medicine, Sir William J. Collins; Section II., Engineering and Architecture, Edwin T. Hall, Esq.; Section III., Physics, Chemistry and Biology, W. N. Shaw, Esq.

MESSRS. Thomas Lewis, M.B., B.S.; C. S. Parker, M.B., B.S., F.R.C.S.; W. B. L. Trotter, M.S., F.R.C.S., Graduates in the Faculty of Medicine of the University of London, have been elected to Fellowships in University College.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

A Case of Tuberculosis of the Pregnant Uterus and Placenta is recorded by Ph. Jung (*Monatsschrift f. Geb. und Gynäkol.*, February, 1906). He thinks it most probable that the placenta became infected through the circulation, owing to the numerous tuberculous deposits all over his patient's system. This agrees with the observations of Schmori and Geipel. The possibility, however, exists in the author's case that the placental infection was due to the tuberculous alterations which existed in the genital organs and peritoneum. In this case, as in two from Schmori and Runge, the placental infection occurred not at the end, but during the progress of the pregnancy, at any rate, before the eighth month. Schmori emphasises that in his two early cases the tuberculous process was localised in the decidua basalis. This was also found by author. Schmori and Geipel believe that a longer or a shorter time before the normal end of pregnancy, tuberculous alterations of the decidua basalis cause hæmorrhages which can lead to premature delivery. From the twenty cases recorded it is proved that tuberculosis already in utero can extend to the child, and a hereditary infant tuberculosis must be recognised. G.

To the Etiology of Fatal Post-Partum Atony Ed. Martin (*Monatsschrift f. Geb. und Gyn.*, February, 1906) contributes details of a case in which, after delivery of the child, such severe hæmorrhage set in that manual removal of the placenta became necessary. This was not possible. The placenta was so closely united to the uterine wall, only a small portion could be removed in little fibrous pieces. The uterus was so extremely thin and flabby that the intestines could be easily felt through it. In spite of hot douching, massage, and tying of the uterine arteries the patient was not saved. On examination of the uterus, the placenta which was inserted from fundus to the internal os seemed in several places to have almost grown through the uterine wall. The muscle clothed the placental mass as a thin layer of tissue. Microscopically, there is an irregularly thin layer of chronically inflamed muscle into which the placental tissue has more or less penetrated. Nitabuch's line is present. Only a trace of the decidua basalis is to be discovered. Author considers that it is very probable that at the time of the implantation of the ovum the uterine wall was in a more or less advanced state of inflammation. The mucous membrane being in a diseased condition, its decidual reaction had produced such a weak resistance in some places to the trophoblast that the basalis was soon overcome, and the former fastened itself directly on the muscular layer. The cause of the atony which must have begun in the first stage is the insufficiency of the muscular layer. It may be considered as certain in this case that the penetration of the cells into the uterine wall was not the result of absence of the basalis, but that the latter, springing from diseased mucous membrane had been quickly destroyed. The large placenta was probably due to an effort to get sufficient nutriment from its diseased bed. G.

A Case of Puerperal Fever Cured through Total Extirpation of the Uterus is recorded by Dr. Oscar Vértés (*Monatsschrift f. Geb. und Gyn.*, February, 1906). The patient had a fibroid uterus. The tumours obstructed the delivery of the child, and prevented the delivery of the placenta. The latter was removed manually. On the third day after delivery, the temperature rose to 39° C, pulse 120, after a rigor. The patient suffered from sapræmia. Her uterus was douched daily. The temperature did not again rise higher than 38.7° C., the pulse varying

between 100 and 120 till the evening of the eighth day, when there was another rigor and the temperature rose to 40°, pulse 140. The general condition of the patient was completely changed. She was evidently very ill, and probably septicæmia had now taken the place of the sapræmia. Owing to this, and to the fact that the myomatous uterus would possibly give trouble afterwards, the operation was decided on before the patient could become completely infected. The abdominal route was chosen. The pelvic peritoneum forwards and backwards was sewn to the wall of the vagina, and a gauze drain inserted from the vagina to the abdominal cavity. As indications for the operation, Dützmänn came to the conclusion from his blood examination in many cases of puerperal and post-operative sepsis, that we can make a prognosis with more or less certainty from the number of the leucocytes. When the latter are increased in number the prognosis is good; where there is diminution death is, as a rule, to be expected. The weakened sickly organism is not always in a position, after fighting for a certain length of time, to produce so many leucocytes as may be sufficient to resist the invading bacteria. When it is possible for us therefore to remove the source of infection before too many bacteria have got into the circulation the patient is saved. The leucocyte counts together with the bacteriological examination of the blood will act as a thermometer of the resisting power of the organism. Sometimes, of course the virulence of the infection is so great that the patients, even though operated on at the earliest stage, die. These cases of "foudroyant" sepsis are, however, rare. The majority present the usual picture of septicæmia or pyæmia. Prochowink von Leopold, Fehling, and others consider the operation contra-indicated when the infection has extended past the uterus. G.

Treatment of Retroflexion of the Uterus by the General Practitioner—Stoedel (*Berlin Klin. Woch.*, December, 1905) believes that in uncomplicated cases of retroflexion the treatment should be rather by conservative methods than by operation. Not every case diagnosed needs correction. Many cases are entirely without symptoms, especially in virgins and old women. Treatment is demanded when bladder symptoms, backache, menorrhagia, and leucorrhœa exist; and for these cases, when there are no adhesions, the author uses a pessary which very often gives relief. When pregnancy exists with retroflexion, it becomes necessary to replace the uterus by gentle bimanual manipulations before introducing the pessary, and to have the patient lie in bed on the side until the uterus has risen above the promontory. Incarceration means gangrene of the uterus from pressure, and the beginning of this is indicated by severe bladder complications. In difficult cases of replacement a catheter is placed in the bladder and the patient put to bed; after a few days an attempt is made to replace the uterus, no narcosis being necessary. The author seizes the vaginal portion of the uterus with forceps, pushes it forward, pushes the fundus up with two fingers of the other hand, and then draws back the cervix. Sterility as arising from retroflexion is doubtful, but in some cases pregnancy takes place after reduction of the deformity. Whether retroflexion is responsible for hysteria is undecided; the application of a pessary often gives relief to the nervous symptoms. The sound should seldom be called into use during manipulations, and when severe pain is produced it is time to stop. Douching is only necessary when there is excessive leucorrhœa. Treat-

ment by pessaries is inapplicable when the retroflexion is complicated by marked prolapse, diseases of the adnexa, salpingitis, tumours, &c., and the symptoms are due to the complications, not to the false position. Glycerine tamponade, rest in bed, local heat, massage, &c., must be used and operation later if relief is not obtained. For the poor working woman we must counsel operation, as she cannot spare the time or strength for long treatment.

Recent Researches into the Bacteriology of Peritonitis in Relation to Pelvic Surgery. By Percy Sargent (*Journ. of Obstetrics and Gyn.*, February, 1906).

Peritonitis is no longer regarded as an independent disease, but is rightly recognised as a serious complication of many widely different pathological conditions. The means by which the peritoneum may become infected are: By accidental operation wounds, by rupture of a hollow viscus, cyst or abscess; by passage of micro-organisms from an inflamed unruptured hollow viscus, cyst, or abscess; by the indirect infection of blood extravasated into the peritoneal cavity in too great a quantity to be disposed of by the natural peritoneal absorption, and by infection by way of the blood stream as in septicæmic peritonitis. What are the micro-organisms which are responsible for the peritonitis arising from these causes, what is their relative frequency, and how may they be scientifically dealt with? The author found that by examining bacteriologically all kinds of peritoneal lesions in many different stages, and by considering the subject as a whole, he was able to differentiate certain types according to the type of infection. The most important and frequent organisms concerned in peritonitis are the staphylococcus albus and the colon bacillus. After these may be placed the streptococcus pyogenes, bacillus pyocyaneus pneumococcus, gonococcus, and rarely the staphylococcus aureus. He places the staphylococcus albus first because it is the organism most frequently found in the peritoneal cavity. It appears, however, to exercise an influence which is the reverse of harmful, for it undoubtedly provokes the appearance of an exudate containing vast numbers of phagocytic cells, on whose presence and their power of dealing with organisms, the chances of recovery depend. In cases of localised pericæcal suppuration, this staphylococcus is found beyond the limits of the abscess in 77 per cent.; when the abscess has been dealt with, and the patient returns some weeks later for the removal of the appendix, the coccus is still present upon the peritoneum in the cæcal region in 62 per cent. The colon bacillus, in one or other of its varieties, is undoubtedly the commonest causative agent of peritonitis, and may exhibit a degree of virulence second only to the streptococcus pyogenes. Apart from puerperal peritonitis, the streptococcus pyogenes is of comparatively rare occurrence as a cause of peritonitis. When present it causes a rapidly fatal form, for the leucocytes appear to be powerless against the infection. The other organisms mentioned as causes of peritonitis in general may be said to be of rare occurrence. In the consideration of the peritonitis arising from diseases of the female pelvic organs the relative frequency of these various organisms becomes altered, and as they vary greatly in their virulence, and the less virulent are most often met with, it follows the mortality from peritonitis in this region is low compared with that of peritonitis in general. The author next deals with the peritonitis met with in gynaecological work. One of the simplest forms is that which follows hæmorrhage into the peritoneal cavity as in extra-uterine gestation. It has been established that there is to be found in the peritoneal cavity and especially in the older clot a white staphylococcus of a low degree of pathogenicity. It is the organism found so frequently in cases of intestinal obstruction and strangulated hernia, and it is the organism which, when inoculated into the peritoneal cavity of guinea pigs, produces such an abundant leucocytosis as to protect the animal against an otherwise lethal dose of the colon bacillus. This white staphylococcus causes both the peritonitis

and the fever. In more than half the cases of pyosalpinx, no organisms are found, the contents of these sacs would therefore be harmless, nearly half the remainder show evidence of the gonococcus, and Dudgeon has shown with the author that the gonococcus can be an actual and probably is, a common cause of peritonitis. In three fatal cases of inflamed ovarian cysts, the lethal organism in two was the colon bacillus and in one the streptococcus pyogenes, though this latter organism is only rarely found with appendicitis. These cases are bacteriologically similar to cases of peritonitis arising from appendicitis and the resemblance is borne out by the white staphylococcus being found in pure culture at a distance from the primary focus of infection. The author concludes that: Pathology teaches that in mild infection, when there is much foreign material to be removed, copious and general irrigation should be employed, but that in the more virulent infections the cleansing treatment should be strictly localised, so as to avoid spread of infection, and removal of turbid exudate containing phagocytes. Bacteriology and practical experience teach:—that drainage is unnecessary in peritonitis, intra-peritoneal hæmorrhage and pyosalpinx, but when arising from a suppurating ovarian cyst, a drain should be employed; that localised collections require ordinary abscess treatment; that opium masks symptoms, favours intestinal paralysis, prevents omentum playing part of scavenger, and inhibits leucocytosis.

F.

Albuminuria in Pregnancy.—Sharp (*Brit. Med. Journ.*, February 24th, 1906) reports a case of "Albuminuria in Pregnancy; Epistaxis; Conjunctival Hæmorrhage," occurring in a secundipara. He was called on January 5th to see the patient, who was suffering from severe epistaxis, which was controlled only by plugging by Bellocq's method. Some hours later she was confined of a still-born seven and a half to eight months' child, and her recovery was uninterrupted. Examination of the urine three days later revealed about 1 part per 1,000 of albumin, and the ophthalmoscope showed a hazy swelling round the optic disc of one eye and a patch of greyish white degeneration. Further it was noticed that blood was slowly dripping from the conjunctival surface of the lower lid on the right side, the side from which most of the bleeding from the nose had come. No blood could be seen coming from the canaliculi or nasal duct. H.

Childbirth after Colotomy.—Under this heading, Dr. Mitchell (*Brit. Med. Journ.*, March 3rd, 1906) relates the following history: A multipara, æt. 28, suffering from complete obstruction due to malignant disease of the rectum, was operated on—left inguinal colotomy being performed, the patient having previously refused an extensive operation. This was in March, 1905. The result of the colotomy was very satisfactory, all the symptoms of obstruction being relieved and almost complete control over the evacuations was obtained. A few months subsequently the patient was found to be pregnant. On January 10th, 1906, less than ten months after the operation, the patient was delivered after podalic version by the combined method had been performed, owing to obstruction caused by the mass of malignant disease in the rectum. The child, weighing 10 to 11 lbs., was full term and living. During the period of gestation there had been no trouble save for pain in the rectum. The puerperium was normal and the patient's condition is fairly comfortable, no secondary deposits having manifested themselves.

- (2) "*Recent Surgical Literature.*"
- (3) "*Recent Gynaecological and Obstetrical Literature.*"
- (4) "*The Recent Literature of Physiology, and Pathology.*"

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

UNQUALIFIED PRESCRIBING.

WA correspondent draws our attention to the fact that certain unqualified persons in the West-End of London are issuing prescriptions to patients. The prescription is drawn up in the usual way, except that the "R" is omitted, together with the final "Misce, fiat mistura." The paper is initialed. Our correspondent asks if such a document does not lay the writer open to prosecution. If the unqualified prescriber took a fee we should imagine that he or she would be prosecuted. In any case we should be glad to receive full information of any such cases that may come under the notice of our readers. It would be essential to secure the documents incriminating, with full statements as to facts.

DR. A. D.—Your point as to the origination of the "expression plan" is of course quite right. In regard, however, to your second point, you forget that though the bed clothes are in contact (as you say) with the vulva for hours, they do not get into the vagina, and in our mind there is a wide difference between the vulva and the vagina. At the same time we, personally, do not allow bed clothes to remain in contact with the vulva, as we are accustomed to treat the latter in a manner very similar to that we adopt in treating an incision into the abdominal cavity.

LAUDANUM AND INFANTILE MORTALITY.

A mixture of laudanum and aniseed, frequently used as a soothing mixture for babies, was, said Dr. Marriott, the presiding magistrate at Stockport, responsible for the death of 15,000 babies every year.

R. M. O. (Midlands).—The outcry against understaffing of the nursing department in Poor-Law infirmaries is of old standing. The only way in which the matter is likely to be made public is when some scandal occurs more or less directly due to inadequacy or inefficiency of nursing arrangements. It is difficult to give advice. Too often scandals are hushed up. The matron, again, is tempted to sweat the nurses and to cut down the staff in order to keep in favour with cheese-paring guardians. The medical man who honestly protests probably brings a hornet's nest around his ears.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 14th.

HUNTERIAN SOCIETY (Court Room, Guy's Hospital).—3.30 p.m. Cases can be examined. 4 p.m. Clinical Afternoon Meeting.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—5.15 p.m. Meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Erasmus Wilson Lecture:—Mr. J. Sherren: The Distribution and Recovery of Peripheral Nerves studied from Instances of Division in Man.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. M. White: Clinique. (Surgical). 5.15 p.m. Lecture:—Dr. F. Stewart: The Cerebro-Spinal Fluid and its Diagnostic Importance.

THURSDAY, MARCH 15th.

CHILDHOOD SOCIETY AND THE BRITISH CHILD-STUDY ASSOCIATION (Parkes Museum, Margaret Street, W.).—8 p.m. Lecture:—Dr. J. W. Slaughter: Imagination in Childhood. (Arranged by the Childhood Society.)

ROYAL COLLEGE OF PHYSICIANS OF LONDON (Fell Mall East).—5 p.m. Goulstonian Lecture:—Dr. E. B. Shaw: Auto-Intoxication.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m. Lecture:—Dr. Langdon Brown: Therapeutical Applications of Adrenalin and Allied Bodies.

FRIDAY, MARCH 16th.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11 Chandos Street, Cavendish Square, W.).—5.30 p.m. Cases and Specimens will be shown by Dr. W. Ewart, Dr. C. O. Hawthorne, Dr. E. Pritchard, Dr. F. J. Poynton, Dr. E. Cautley, Dr. K. E. Hay, Mr. D. Drew, Mr. H. Lett, and others.

EPIDEMIOLOGICAL SOCIETY (11 Chandos Street, Cavendish Square, W.).—8.30 p.m. Paper:—Dr. J. T. C. Nash: Evolution in Relation to Disease.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Erasmus Wilson Lecture:—Mr. J. Sherren: The Distribution and Recovery of Peripheral Nerves studied from Instances of Division in Man.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. M. Yearsley: Clinique. (Ear.)

Vacancies.

Birkenhead and Wirral Children's Hospital, Woodchurch Road, Birkenhead.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to F. W. Archer, 25, Storeton Road, Birkenhead.

Bradford Children's Hospital.—House Surgeon. Salary £100 per annum. Applications to C. V. Woodcock, Secretary.

Bristol House Private Asylum, Bristol.—Assistant Medical Officer. Salary £180 per annum. Applications to the Resident Licentiate.

British Ophthalmic Hospital, Jerusalem.—Assistant Surgeon. Salary £300 a year, with residence. Applications to R. Brudenell Carter, F.R.C.S., 76 South Side, Clapham Common, S.W.

Corporation of Sheffield.—Fever Hospitals.—Junior Assistant Medical Officer. Salary £120 per annum, with board, lodging, and washing. Applications to H. Sayer, Town Clerk, Town Clerk's Office, Town Hall, Sheffield.

Dr. Steevens' Hospital, Dublin.—Anesthetist. Applications to the Secretary at the Hospital.

King Edward VII. Sanatorium (Midhurst).—Assistant Medical Officer. Salary £150 per annum, with board and residence. Applications to the Secretaries, 35 Seymour Street, Portman Square, London, W.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary £150 per annum, together with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Metropolitan Hospital.—Casualty Officer. Salary £150 per annum. Applications to Charles H. Byers, Secretary.

Middlebrough.—North Ormesby Hospital.—House Surgeon. Salary £120 per annum, with apartments and board. Applications to R. T. Milner, Secretary, Royal Exchange.

Taunton Isolation Hospital.—Medical Attendant. Salary £120 per annum. Applications to W. F. B. Daws, Clerk.

The London Hospital Pathological Institute.—Director. Salary £200 per annum. Applications to Munro Scott, Warden, The London Hospital Medical College, Turner Street, Mile End, London, E.

West Kent General Hospital, Maidstone.—House Surgeon. Salary £120 per annum, with board and residence. Applications to W. C. Lewis, Secretary.

West Norfolk and Lynn Hospital, King's Lynn.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to the Chairman of the Hospital.

West Riding County Council.—Scalebar Park (Private Asylum), Burley-in-Wharfedale.—Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, attendance, &c. Applications to the Physician Superintendent.

Appointments.

HEGGS, T. BARRETT, M.D., Ch.B.Aberd., D.P.H.Camb., Medical Officer of Health to the combined Districts of Sittingbourne and Milton, and Medical Superintendent of their Isolation Hospitals.

HITCHINS, CHARLES VERNON, M.R.C.S. L.S.A., Honorary Consulting Surgeon to the Weston-super-Mare Hospital.

MATLAND, LYTTON, M.B., B.S.Lond., House Surgeon at the Great Yarmouth General Hospital.

MASEWELL, JOHN WILLIAM, M.R.C.S., L.R.C.P.Lond., an Honorary Medical Officer to the Chorley Dispensary and Rawcliffe Hospital, THOMPSON, WILBERFORCE, L.R.C.P.Lond., M.R.C.S., L.S.A., D.P.H. Lond., Medical Officer of Health for the Bridgwater (Somerset) Rural District.

TOSWILL, LEONARD ROBERT, M.R.C.S., L.R.C.P.Lond., Honorary Surgeon to the Exeter Dispensary.

TREBIDDER, WILLIAM ELLIOT, M.B., B.S.Lond., Medical Officer for the Chudleigh District by the Newton Abbot (Devon) Board of Guardians.

WOODHOUSE, ORCIL, M.D., B.C.Cantab., Clinical Assistant to the Chelsea Hospital for Women.

Births.

HARRIS.—On March 2nd, at the Manor House, Southwick, the wife of Henry Arthur Clifton Harris, M.R.C.S., L.R.C.P., of Brighton, of a son.

SIBLEY.—On March 8th, at Abercorn, Hanger Lane, Baling, the wife of Osbert Carden Sibley, L.P. and L.S.A.Lond., of a son.

WILLIAMS.—On Jan. 31st, the wife of E. Bridgman Williams, M.R.C.S., of Newcastle, Natal, S. Africa, of a daughter.

Marriages.

HORNIBROOK-THOMSON.—On March 7th, at the Chapel Royal, Dublin Castle, Murray Hornibrook, Esq., of Templemore, Co. Armagh, to Gladys, only daughter of Sir William Thomson, M.D., M.Ch., L.R.C.S.I., Hon. Surgeon to H.M. the King in Ireland.

PURSER-INGLIS.—On March 10th, at St. Andrew's Church, Upper Norwood, Captain L. M. Purser, Royal Army Medical Corps, to Hilda, youngest daughter of the late A. B. Inglis, Esq., of Calcutta, and Mrs. Inglis, of Upper Norwood.

Deaths.

BLYTH-WYNTER.—On March 11th, at Cairo, Annie Elizabeth, wife of A. Wynter-Blyth, M.R.C.S., of St. Marylebone.

MEEBREWSTER.—On March 7th, at Simon's Bay, Cape Colony, from malignant malarial fever, Staff-Surgeon Alworth L. Merewether, M.B., B.S., M.R.C.S., L.R.C.P., Royal Navy, I.I.M.S. "Crescent," aged 38 years.

MEYRICK-JONES.—On March 8th, at Rio de Janeiro, Arthur M. Meyrick-Jones, F.R.C.S.E., eldest son of the Rev. G. M. Meyrick-Jones, of Stanley House, Gloucestershire, aged 43.

PATERSON.—On March 9th, at 46 Beaumont Street, Portland Place, London, Adam Black Paterson, M.D., aged 81.

STARK.—On March 7th, at Torquay, Mark Dugald Stark, M.D., of 6 Broad Street, Oxford.

WILLIAMS.—On March 7th, at Abernig House, Talgarth, B.S.O., Breconshire, Thomas Edward, F.R.C.S.E., J.P., in his 65th year.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXII.

WEDNESDAY, MARCH 21, 1906.

No. 12

NOTES AND COMMENTS.

A False and Defamatory Libel.

MEDICAL men are specially open to attempts at blackmailing. There can be little doubt that many such charges have attained their nefarious object because of the difficulty of proving their falsity. Nowadays the services of the Medical Defence Union or of one of the junior protection Societies are available for their members. Sooner or later the attack of the blackmailer has to be faced by almost every member of the profession, no matter what his rank or standing. Early in the present month a man named Foxlee pleaded guilty at the Central Criminal Court for uttering a false and defamatory libel concerning Dr. Arthur Waddell, of Potter's Bar. The reckless bitterness of this wretched person led him into the actual publication of a circular, in which he stated that the prosecutor was intoxicated and neglected his duties while attending his wife on a certain date. Further, he charged Dr. Waddell with performing upon his child a cruel and unnecessary operation, whereby permanent injury had been inflicted.

The Bitter Bit.

READING between the lines, the apparent motive of the attack was blackmail, nothing more nor less. That was the view taken by the prosecuting counsel when detailing the annoyances and threats which Foxlee inflicted upon his victim. Letters advising settlement with a view to avoid publicity being disregarded, the matter culminated in the issue of the libellous circular. Fortunately Dr. Waddell is not the kind of man to become the prey of blackmailers. He prosecuted Foxlee for libel with the result that the defendant on promising not to repeat the libel, was bound over in two sureties of £50 to come up for sentence if called upon. At the same time the Recorder told Foxlee he was extremely fortunate in not having been indicted for attempting to extort money by threats of publishing the libel, for if he had been convicted he would have been sent to prison. The law is surely defective if it cannot imprison a man for conduct so base and criminal as that pleaded guilty to by the defendant. The absolute falsehood of the libel may be inferred from the single fact that Dr. Waddell is a total abstainer. We congratulate him on his prompt vindication of his own reputation and of the honour of his profession.

A Tooth Extractor.

A CURIOUS case has just been before the Coroner's Court at St. Helen's. The evidence showed that a boy of eight was taken by his father to the market place of that town on January 19th last, when he had two teeth extracted

by a "lightning tooth extractor," named Mitchison. Another "extractor" subsequently removed two stumps said to have been left behind by the first operator. The poor boy died on March 4th as the result of septic infection. The gentleman with the claims to lightning speed stated that he had three places of business in St. Helen's, and had been an extractor of teeth for about sixteen years, and on certain days extracted teeth in the market gratis. The jury found death was due to blood poisoning, but did not attach any blame to anyone. The illogical state of English law as regards the Dental Acts, could hardly be better illustrated. Although the science and practice of dental surgery has been placed on a definite and legitimate basis, it is, nevertheless impossible to put an end to that dangerous and reckless pest of society—the itinerant tooth extractor.

A Chemist's Error.

THE action brought by an Arbroath minister against a local chemist for the wrongful dispensing of medicine, whereby the pursuer's daughter was injured, has been settled on appeal. The fact that strychnia was dispensed instead of codeia was admitted. The Sheriff who delivered judgment appears to have confined himself mainly to the question of damages, which were laid at £100. The chief point insisted upon in the decision was that the extent and amount of the resulting injury was not definitely proved. The former decision was sustained, namely, that the defender should pay the expenses of the action, with the exception of certain fees for analyst and other expert evidence, together with three pounds damages. The result of these protracted lawsuits is not encouraging to persons who may in the future suffer from careless dispensing.

Salicylic Acid in Jam.

THE dismissal in Liverpool of another prosecution for the use of salicylic acid as a food preservative adds to the prevailing confusion upon a vital question. The prosecution has asked leave to state a case, and it is to be hoped that appeal will settle the point definitely one way or the other. Medical testimony in the case was contradictory. One set of witnesses maintained that salicylic acid in jam was harmful and the other harmless. For our own part we fail to see why properly made jam wants the addition of a chemical preservative. With proper boiling and proper packing jam should keep sound and wholesome for many years. The addition of preservatives to such perishable food as sausages stands on another footing. In the interests of the public the whole question of food preservatives should be authoritatively and definitely settled.

LEADING ARTICLE.

PUBLIC NEWSPAPERS AND QUACK ADVERTISEMENTS.

WE are happy to believe that the public newspapers of the United Kingdom may on the whole be regarded as high in principle and aim. As regards the particular detail of quack advertisements, however, with hardly a single exception, their attitude is one of reckless and venal negligence. It is hardly possible to pick up at random any daily or weekly journal published in this country that does not contain advertisements of so-called remedies and "cures" of an obviously false and therefore fraudulent nature. The purchasers of worthless medicines or apparatus are induced to spend their money on the strength of the lying assertions contained in the puffs, for which a high rate of payment is exacted by publishers. In other words, the proprietors of such a journal, the editorial staff and all who make a living, directly or indirectly, out of the publication partly draw their living wage from money wrung out of the pockets of the poor, the sick, and the afflicted, by the lying statements of quacks. Yet while this pernicious practice is swelling the profits of the journal on the one hand, the editor on the other may be posing as a representative of the highest ideals of justice, freedom, and uprightness. Following our usual practice, we take up a journal at random in order to illustrate our remarks. This week we turn to *Reynolds' Sunday Newspaper*, a journal which is particularly loud and emphatic in its appeals to a higher social and political morality. It seems to us that it is futile for the Editor to fan the flames of social unrest with unsparing zeal in the interests of the community, while he is at the same time making money by attracting a host of victims to the snares of the most monstrous villain of modern society, namely, the quack medicine vendor. Turning to the issue of *Reynolds'* for March 16th, 1906, we find one benefactor of mankind advertising to "cure" rheumatism by a new remedy, of which he offers to the public 50,000 boxes free. The term "rheumatism" is a wide one, and there is no drug or combination of remedies known to medical science that can be guaranteed to cure all cases of any single variety. A certain drug, it is true, exercises a specific control over many cases of acute rheumatism, but even in the most skilful hands it fails occasionally, and death or serious complications may arise in spite of every care. To use this drug successfully demands the utmost care and skilful supervision on the part of a medical man. Supposing, then, that an ignorant layman got hold of this drug it would be far more impossible for him to cure all cases of acute rheumatism, for less all cases of all varieties of rheumatism. In other words, the advertisement is a wicked and palpable lie, and *Reynolds'* has accepted money for its publication. How about the purchasers of this nostrum, who are possibly or probably throwing away their only chance of

escape from hopeless heart disease or chronic joint disease by deferring properly qualified medical treatment in favour of the stuff advertised by an interested proprietor in the columns of an interested newspaper. The vendor is not content with the preposterous claim that his wares can cure rheumatism, but he adds gout to the list. There is absolutely no remedy known to science that can cure both maladies. The specific that cures many cases of acute rheumatism is useless in gout. These facts we offer seriously and emphatically to the consideration of the Editor of the journal in question. We have no intention of criticising the sordid series of advertisements of a similar nature that appear in the same issue. We may just mention in passing Veno's lightning cough cure, which asserts in bold type that pleurisy and congestion of the lungs are cured by its use. That any medicine can exercise a specific influence over pleurisy, in other words, can cure that affection, is inconceivable. To say so is, in plain Saxon, to state a lie. Pleurisy is the outcome of many diverse conditions—not infrequently it is due to unsuspected tubercle. In any case, we should say as our deliberate opinion that any person suffering from pleurisy who trusted to Veno's lightning or any other particular remedy would thereby greatly lessen his chances of recovery. The death of such a person under such circumstances would under any properly conceived scheme of social order be laid at the door of the vendor of the nostrum. Moreover, the death would be indirectly due to the Editor and the publisher of *Reynolds'*, or of any other paper that had given publicity to the lying assertions of the nostrum vendor. As a simple matter of fact, the three persons mentioned are parties to a conspiracy to obtain money under false pretences. We fancy that if a death occurred under such circumstances as those above suggested that a heavy action for damages might be brought with a fair chance of success against all concerned. Finally we may say that we have no personal feeling against *Reynolds' Newspaper*, which we believe to be neither better nor worse than most of its fellows. In succeeding numbers the searchlight will be turned in various directions, and we shall hope at some future day to be able to point out newspapers whose columns are purged of this most cruel, heartless, and abominable class of advertisement.

As the result of generous contributions to the Queen Victoria Memorial Hospital at Nice, which was opened by Princess Christian on Saturday last, there will be, from the commencement of its career, 36 beds, of which no fewer than 24 will be entirely free for poor and necessitous cases, whilst another eight will be provided for persons of very limited means, but who yet desire to pay some small acknowledgment for the benefit they receive. There will also be four beds for paying patients, who, from accidental circumstances, are forced to avail themselves of the advantages of an English hospital. At least one-half the free beds are already either permanently endowed or subscriptions for their special maintenance promised. The late Sir John Blundell Maple gave £3,700 to the fund, and Sir George White has given £3,000. Over £12,000 has already been collected.

NOTES ON CURRENT TOPICS.

A Medical Banquet.

THE account which is given by a contemporary of what, for want of a better name, we must be content to designate as the dining-room of a medical gentleman in London, will, we fear, be apt to make the mouths of the more socialistic and less successful of his confrères water, and their hearts formulate more or less trite sentiments on the unequal distribution of wealth. To mark a special occasion, a "banquet" was given to the members of the local medical society. It "took place in the Court of White Marble built by the host at his residence. The guests were welcomed in the study, which is remarkable for its Egyptian decorations, and from this room admission was obtained to the court by a flight of marble steps flanked on each side with a bas-relief of a lion attacking a bull, copied from the ruins of a well-known palace at Persepolis. The court, which is a replica of the Paris model of the marble hall of the great King Artaxerxes, the son of King Darius, contains thirty-two columns each sixteen feet high. On the top of these the heads of Assyrian bulls support the roof. The columns are gleaming white and stand out against the walls, which are faced with enamelled bricks of a pale greenish-blue fading into straw colour. The frieze represents the black and white archers of the bodyguard of the great king. A striking decoration is the symbol of Ormuzd, the Persian spirit of creation and of good, presenting wide wings in deep turquoise blue enamel tiles with a very fine effect. To appreciate fully the beauty of this exquisite court of dazzling white marble, with its walls flooded with tender enamel tints, it is necessary to supplement description with inspection, and it certainly affords an interesting example of a type of architecture peculiarly Persian." It is presumed that at the termination of the "banquet," to maintain ancient form, the custom of the introduction of some *memento mori* was followed, though in this case the place of the skeleton might well have been taken by a pauper suitably clad to moralise on the vagaries of recently-acquired wealth. We trust that those who were privileged "to supplement description with inspection" made the most of their opportunities.

Capsuloids.

DOUBTLESS many of our readers have seen, from time to time in the advertisement columns of the lay press, glowing advertisements of a preparation bearing the euphonious title of "Capsuloids," which profess to be the scientific remedy for the falling out of hair and for prematurely grey hair, and doubtless, too, they have lately received a booklet on the same subject from the Capsuloid Company. It is little less than astonishing that a commercial company which advertises a preparation of this kind to the public can be so ignorant of the usages and sentiment of the medical profession as to try to engage their co-operation

in the sale of goods which are exploited as "Capsuloids" have been. Nor will medical men be less astonished if they take the trouble to read the booklet sent to them. They will learn that medical practitioners, especially family physicians, have frequent occasion to regret their inability to prescribe for patients who consult them for the purpose of checking "falling" hair, and that in obstetrical practice there is a great demand for a remedy for this condition. Their "inability to prescribe" apparently arises from ignorance of dermatology, a defect which the Capsuloid Company endeavour to remove by a dissertation on the pathology of "falling" hair. Of this dissertation we can truthfully say three things: that it does contain a good deal that is new to us, that what is new is not true, and that what is true is not new. The whole wonderful secret that the Capsuloid Company reveal to the profession is that "falling" hair is due to malnutrition, and to microbial invasion of the hair-follicles, and that "Capsuloids," being a preparation containing hæmoglobin, is the long-sought cure. "We are well aware," with this enterprising Company, "that it is an *absolute innovation* for anyone to suggest to a physician that there is a cure for the falling out of hair." For ourselves we can only express the hope that any further innovation of the kind will come from accredited sources.

A Criminal Lunatic.

A SHOCKING tragedy was revealed at the trial of one, Edward MacQuire, at the Old Bailey last week. The prisoner had been an inmate of St. Pancras Workhouse, where he was found to be insane, and after detention in the mental ward of that institution he was removed to Colney Hatch Asylum. While at the workhouse he had conceived a grudge against the superintendent of the mental ward, and on his discharge from Colney Hatch he threatened him several times with violence. Last December MacQuire found an opportunity, and when Skinner, the object of his dislike, was entering his house, the wretched lunatic shot at him and wounded him fatally. At the trial the defence relied on an *alibi*, which was easily seen through and discredited by the jury, who found the prisoner guilty but not responsible for his actions. He was consequently ordered to be detained during the King's pleasure. Occurrences such as these demonstrate a lamentable hiatus in our lunacy laws and administration. An asylum superintendent cannot detain a patient whose reason has become restored, or apparently restored, while under care, though he knows that to discharge him is probably to expose society to a dangerous and irresponsible pest at some date in the future. There seems to be a morbid fear in the minds of our legislators that the freedom of the subject will be trenced upon by restraints on persons who have temporarily recovered from mental disease or who, though mentally weak, have not committed any outrageous act. Surely the science of preventive

medicine should be extended to embrace these contingencies, and in so doing have the warm-hearted support of all good citizens.

Exclusion of Scotch and Irish Qualifications from English Hospitals.

THE grievance under which medical men holding Scotch and Irish qualifications suffer in being excluded from hospital appointments in most of the large London and many provincial hospitals is likely to be much in evidence in the near future. It represents the survival of a trades unionism of the least desirable kind on the part of the London Colleges. The matter has long been one of the standing subjects for discussion in the large and important Irish Medical Schools and Graduates Association. In their dinner at the Hotel Cecil on St. Patrick's Day, the president adverted to the exclusion of Irish and Scotch graduates and diplomates, and, in the hope of common action, welcomed the presence of the secretary of the Association of Scotch Diplomates among their guests.

The Medical Defence Union.

THE Medical Defence Union deserves the undying gratitude of the medical profession. Where others grumble and do nothing the Union prosecutes. Last week it secured the conviction of a man whom the magistrate spoke of as "a particularly impudent impostor," in the person of Thomas William Tyrrell, for unlawfully pretending to be a doctor. The defendant carried on an extensive illegal practice under the title of "Dr. Muschik," at Marble Arch and two other addresses in London. A man in perfect health consulted "Muschik" and was told he was suffering from fever. He obtained a certificate to enable him to stay away from business and was charged a fee of five guineas, afterwards reduced to three. The wonder is that the Government and the police permit such gross frauds to be carried on in the full light of day. Greater still is the wonder that irresponsible newspaper editors and proprietors play into the hands of such rogues and impostors and share their profits by accepting their nefarious advertisements. We are glad to say that this particular swindler had to pay a fine of £60, with £10 10s. costs. If the police would only follow up Tyrrell his career as a bloodsucking charlatan could, with little difficulty, be effectively cut short.

Too Much Light.

THERE are times in science as well as in politics when a reactionary wave of thought threatens to disturb the peaceful sea of settled convictions. The potent influences of light, whether that of the sun itself or that derived from the electric current, and the wonderful effects of the invisible rays of the spectrum in alleviating human suffering have never been doubted for a single moment, even by those who are not professed advocates of radiotherapy. Careful observers, however, with-

out seeking to decry the benefits to be obtained by the use of light as a therapeutic agent, are beginning to find out that it is quite possible and not at all uncommon to have too much light as of any other good thing. In other words, excessive light acting upon the human organism may, and does, under certain conditions, produce effects which cannot be called other than pathological. The effects of tropical light upon white men have been fully worked out by Major Woodruff, who has shown definitely that the blond races which migrate southward do not permanently survive. More recently the same observer has described neurasthenic states which he believes are accounted for by nothing less than the increased metabolism caused by excessive light. Thus, it has been found that in the Philippines the mortality among infants is much less when they are kept indoors than when taken out and exposed to sunlight. In adults, gloomy and dull weather is also shown to have an exactly opposite effect to that which it is popularly supposed to have. The harmfulness of light upon the human skin has been noted by many modern French writers, and from America we have Dr. Nevins Hyde speaking out very strongly upon the influence of light in the production of cancer of the skin. Physiological pigmentation of the skin, as in the coloured races of mankind, appears to confer upon them a relative immunity against malignant disease of that organ. The whole question is one of intense interest at the present moment, and it is not impossible that many of the existing views with reference to actinotherapy will have to be considerably modified in the light of recent communications.

Examination of Motorists.

WE understand that the French Government is about to introduce some new and rather startling regulations with regard to motorists. If these be carried it will be necessary for everyone who wishes to drive a motor to produce evidence of having passed a thorough test as to his capabilities to manage a car, and also of having passed a medical examination. We are not surprised that the latter should be in contemplation. It has long been necessary that railway men and sailors should be able to demonstrate the acuity of their eyesight, for it is a known fact that many people are quite ignorant that their vision is defective, and not a few appalling accidents by land and sea have resulted therefrom. That a motorist, who in France is under no restriction as to speed, should be myopic is a public danger of no small degree, and no less so that he should be a drunkard or the victim of a grave organic disease. In England, though the rate of motor progression is defined by law, it is competent for

a person to take out a driver's licence without anyone knowing or caring if he can drive or not, whether he is trustworthy or not, whether he is the subject of disease or not. And for a man to drive a motor even at fifteen miles an hour who is not both capable and sound is a serious matter. On the whole, we are inclined to agree that a medical examination for motorists, at least as regards eyesight and general physiology, would be an excellent thing. We hope the point will receive the attention of the Automobile Club.

"Truth" on Testimonial-Mongering.

ALWAYS in the track of the charlatan, our vigorous contemporary *Truth*, in its issue of March 8th, gives some vivacious revelations of American methods for getting testimonials for quack medicines. The worst of it is that it appears that now our home nostrum-market has been invaded by the sharks from the States their methods are being employed over here. It is asserted that a regular business is carried on by recognised agents for obtaining testimonials, but so far Great Britain has not adapted itself to this trade, and that testimonials are either pure forgeries, or given in return for a present of photographs, or signed by relatives or friends of the proprietors. One lady is apparently retained by a patent medicine firm at a retainer to answer questions addressed by customers, and she proceeds on application to give her experiences of a preparation which she has never needed and never used. Another "ghost" is known who acts on similar lines from an address where he cannot be found when wanted, and in a third case the person who supplies photographs and testimonials lives in a block of almshouses. The American patent medicine that pays best is one that creates a habit of some kind by supplying the purchaser with a drug such as morphia, or cocaine, or alcohol, to which he may become addicted, and many ladies' medicines are popular for this reason only. A cynical magnate of the patent medicine trade, who advertised to cure rheumatism, informed our inquirer that he did not want to cure rheumatism, but only to give a medicine "full of hope," which made people want to buy more and more of it. We may be innocent, but we believe we are still free from this particularly heartless kind of knavery. Let us hope we shall never meet with it over here.

Lead an Abortifacient.

THE medical and lay papers alike have paid much attention during the past few weeks to the growing custom of using lead in some form or other to produce abortion. It appears that within the last eight or ten years, the working classes over a wide district in Northern Yorkshire and the Northern Midlands have gained knowledge of the ecboic effects of lead, and medical men have from time to time drawn attention to the putting of this knowledge into practice. The evil seems to be spreading, and curiously enough is spreading so slowly but so continuously as to

justify the belief that information passes from person to person, without, at any rate to any extent, the aid of print or of quack vendors. The usual form of lead employed appears to be diachylon, the purchaser concocting pills therefrom herself, according to some crude recipe. While lead is probably a fairly efficient ecboic, its use is, apart from all moral considerations, accompanied by such serious consequences of poisoning to the woman herself that no effort should be spared to prevent the further spread of the custom. Medical men must be on the watch to detect lead poisoning in all cases of anæmia or colic, and steps should be taken to warn druggists against the indiscriminate sale of lead, and particularly of diachylon.

The Police and Prescribing Herbalists.

A RECENT tragedy at Cefn raises some important issues regarding herbalist practices. A married woman of that place died after a miscarriage and a Coroner's inquiry revealed the fact that she had been taking medicine prescribed ostensibly for bronchitis by a local herbalist. Analysis, however, revealed the significant fact that the herbalist's stuff contained abortifacient drugs. Under such circumstances it is inexplicable how the herbalist escaped a criminal prosecution. He may, indeed, consider himself lucky to have experienced nothing more discomfoting than a severe censure from the coroner. Upon men of his kidney reproof of that kind leaves no more impression than the proverbial water on a duck's back. But, where are the police? Apart from the question of procuring abortion there is a strong assumption that the herbalist might be prosecuted under the Apothecaries or the sale of Poisons Acts. A reference to the case, which is reported in another column, will show that the man admitted in open court that he wrote prescriptions and ordered chloroform. Surely if he has sold and prescribed dangerous and poisonous drugs he could be proceeded against under the Sale of Poisons Act. It is a public scandal that an ignorant man, "unable to spell ordinary words," should be permitted to prescribe dangerous drugs and play with the lives of his fellow citizens. We trust that the Medical Defence Union and the Apothecaries Company will look into this particular case.

PERSONAL.

ON the 31st instant the Mayor of Bath, C. P. Oliver Esq., J.P., and the Corporation will receive the members of the British Balneological and Climatological Society in the famous Pump Room of that city. The Roman baths will be open for inspection.

MR. R. HENSLOWE WELLINGTON has been appointed Lecturer in Forensic Medicine at the Westminster Hospital Medical School. In addition to his medical qualifications, he is a practising barrister of the Middle Temple and South Eastern Circuit. He is deputy-coroner for the City of Westminster, and for the County of London, and the author of "The King's Coroner."

SEÑOR MANUEL GARCIA, the inventor of the laryngoscope, on March 17th completed his 101st year.

A CLINICAL LECTURE

ON

ANGINA PECTORIS: TRUE AND FALSE.

By Professor BUCHARDT, M.D.,
Of the Faculty of Medicine, Paris.

[Specially reported for this Journal.]

ANGINA PECTORIS, as you are doubtless aware, is a syndrome characterised by attacks of paroxysmal pain, of sudden onset, in the region of the heart, or along the left sternal border, associated with intense anguish and the apprehension of impending death. It usually supervenes during or after an effort, such as climbing or rapid walking against the wind. The victim is, so to speak, immobilised by the pain, he is pale, and his face is expressive of intense anxiety. The pain radiates in the direction of the left shoulder, the neck—the jaw, the tongue, and the left arm, right to the ends of the last two fingers. It may involve the pharynx, giving rise to a sensation of constriction followed by aphonia, nausea, and vomiting, with hiccough the pain may even find an echo in the testicle. The patient feels that he is on the verge of death and that the heart will infallibly cease beating if the crisis be prolonged.

These striking features of angina pectoris are familiar to all medical men, and there is no divergence of opinion as to the clinical aspect of the syndrome. Opinions only begin to clash when we make an attempt to elucidate the cause of the affection, and to trace it back to its particular source of origin. Yet we cannot dispense with this investigation, for it has an important bearing on prognosis. It is highly important that we should know whether we are dealing with a case of grave angina pectoris, likely to have a fatal issue because consequent upon some irremediable anatomical lesions, or whether the case is a comparatively benign one due to purely functional disturbance, and therefore amenable to treatment. The question we have to discuss is whether there is anything in the clinical examination of the patient that will enable us to arrive at a conclusion in one or the other direction. Incidentally we must inquire what light is shed on the question by pathological anatomy.

The anginal syndrome is met with in connection with a large number of very different affections. Andral has met with it in pericarditis; Corrigan and Hirtz in acute aortitis; Hugenin in myocarditis, dyscrasic affections (diabetes, gout), and diseases of distant organs—liver or kidney—infectious diseases, malaria, rheumatism, hysteria, intoxications by tobacco, lead, tea, oxide of carbon, and so on.

In presence of so many etiological varieties, it is difficult to resist the assumption that the same physiologico-pathological mechanism must be at work, since the clinical manifestations are approximately the same in all. Gilbert and Garnier, after a close scrutiny of the opinions of various authors, arrived at the conclusion that the anginal syndrome is always of neuralgic origin or the result of a toxic neuritis of the cardiac plexus, the gravity of the evil varying according to the cause. According to these observers a rigid milk diet is the sovereign remedy. This opinion coincides approximately with that of Peter and Lancereaux, who assign the cause of the malady to a neuritis of the cardiac nerves. The nervous theory, indeed, has numerous partisans apart from those already mentioned—Laennec, Trousseau, Axenfeld, Parrot, Jaccoud, Bouchut, &c.

Personally, I am convinced of the coronary origin of true angina pectoris. In my experience, there is invariably stenosis of the two coronaries or blockage of one of them. It is true that *post-mortem* examination sometimes fails to reveal this narrowing, but we

must not forget that the existence of arterial spasm, secondary to a neighbouring inflammatory lesion (pericarditis, aortitis, &c.), may result in cardiac ischæmia and determine the characteristic symptoms. This theory was formerly defended by Kreysig, and in opposition thereto the following objections were formulated. To begin with, ossification of the coronary arteries may exist without any sign of angina pectoris; moreover, during the whole period of ossification and narrowing of the calibre of the vessels, no attack of angina may be observed, in spite of the defective circulation; and, lastly, physio-pathology shows that the symptoms observed in animals consequent upon experimental obliteration of the coronaries differ markedly from those observed in human beings. We may mention also the theory formulated by Professor Potain, who likened the anginal attack to intermittent paresis of the extremities.

According to Professor Gilbert all cases of angina pectoris are dependent upon the same mechanism, and he locates the mischief in the cardiac plexus. The disturbance may be merely functional, and consist in reality in a sort of neuralgia, or, on the contrary, there may be a genuine neuritis with obvious structural changes. But, says this observer, though the pathological physiology is the same in all cases, the etiology differs in each case. As a rule the cause is toxic, and of all intoxications the commonest is that of uræmia. It may, however, be reflex, or it may be toxic-infectious and associated with a pericarditis or aortitis. Lastly, in some cases, the nervous symptom must be invoked, since hysteria does sometimes give rise to the complete syndrome. The toxic form of angina alone is of grave import, and the principal factor in determining its gravity is its cause. When the latter is of a fugitive character, as in poisoning by tobacco or caffeine, recovery will take place promptly enough when the underlying cause has been obviated. When permanent, as, for instance, when it is dependent upon irremediable changes in the kidneys, the attacks are sure to recur at more or less distant intervals.

To sum up, there does not seem to be any trustworthy character that will enable us to distinguish between true and pseudo-angina. We diagnose severe or benign angina according to the cause that has brought it about and the pathological importance of this cause, but the syndrome is always the same and does not admit of any clinical classification.

Certain features have, however, been suggested as more characteristic with mild anginas rather than the graver variety; indeed, Huchard enunciates four clinical rules which he asserts will never be found wanting:—

- (1) Whenever an attack of angina pectoris is precipitated by any sort of effort—a quick walk, for instance, it is true or coronary angina.
- (2) When the anginal attack comes on spontaneously, *i.e.*, is not the result of a physical effort, the case is one of pseudo-neuralgic angina.
- (3) When a patient who has attacks consequent upon muscular effort also has spontaneous attacks during the night the first rule is not invalidated, for it is always a case of true angina.
- (4) Thoracic pain produced by pressure is not anginal. Pain provoked by effort, then, is characteristic of coronary stenosis; pain provoked or aggravated by pressure is due to phrenic intercostal or

diaphragmatic neuralgia. Spontaneous pain so frequently met with in dyspeptic, neurasthenic and hysterical subjects presents no importance, and stands in no relationship to a coronary lesion; in other words, it does not constitute real angina.

Whatever the precipitating cause of the anginal attack, we must bear in mind that the victim may succumb. In smokers and in hysterical subjects we sometimes meet with mixed cases in which the grave element is associated with the benign form, as, for instance, when sclerosis and some form of intoxication (sclero-tabagic intoxication) are working on parallel lines.

Tobacco angina pectoris holds a foremost place in the numerous category of pseudo or benign anginas. It resembles the coronary variety so far as its pathological mechanism is concerned (arterial spasm), viz., by the etiological part played by muscular effort in its production and by the possibility of sudden death, which, however, is fortunately the rare exception. It differs from the true coronary form by the more marked spontaneity of its onset, by the greater duration of the attacks, by the præcordiac and not retro-sternal situation of the pain, by its association with other vaso-motor disturbances and the presence between the attacks of various uncomfortable symptoms familiar to most smokers, such as vertigo, faintness, and cardiac intermittences.

We discuss some of these symptoms more in detail in another paper. Tobacco angina is abnormal in respect of its site. The pain is referred to the præcordium and not to the true angina pectoris, to the retro-sternal region, the attack often lasts half an hour or more; moreover, vomiting, epistaxis, vertigo, cold sweats and coldness of the extremities not present in angina pectoris are also present in tobacco angina. Then, again, the antecedents of the patient will always afford valuable information. We must always bear in mind the pro-association of tabagism with cardio-sclerosis, and therefore so seeing that, according to Renon, nicotine poisoning is itself an influential factor in the production of aortic aortitis and arterio-sclerosis.

Hysterical angina pectoris presents certain peculiarities which I think deserve special attention. Together with it, it is hereditary and occurs in the offspring of hysterical parents. It may supervene at any age, more particularly at the menopause; it often occurs in association with certain cardiac affections, of which, however, it is usually quite independent. It may be excited by auto-suggestion, the patient having been misled by the dyspnoea of a real cardiac patient, accentuating her emotivity. Numerous instances of this form of pseudo-angina have been observed by Peter, Talamon, and others. According to them, the same disease may manifest itself in grave abortive attacks. The attack is usually at the præcordium and is accompanied by præcordiac distress and intense pain. It is preceded by a cardiac aura, which is vaso-motor or neuralgic. In the neuralgic form the pain starts at the finger-ends, mounts up the arm, reaches the trunk, and lastly the heart. It may start in the loins, the lower limbs, the ovary or the testicle, though the last-named is rare.

The vaso-motor aura is characterised by a feeling of coldness, with "goose-flesh" and pallor of the skin, cyanosis, faintness, enfeebled heart-beat, and even actual syncope. This applies to the grave forms. In the cardiac aura there is violent palpitation with irregularity of cardiac rhythm, or slowing-down of the pulse.

The auras take origin in hyperæsthetic zones of which the irritability has, so to speak, been suddenly intensified. On close examination we find tender spots in the præcordia, over the apex of the heart, along the spinal column, or over the ovary. From these points the pain radiates into the arms, the hypochondria, the ovaries, &c.

Along with these symptoms we get emotional disturbances, mental anxiety and respiratory troubles, which are usually absent in true angina pectoris.

By looking out for these phenomena we shall derive material assistance in arriving at a correct differential diagnosis. Nevertheless, we must not trust this form with contempt, for Potain records having seen two instances of death from hysterical angina, which confirms what I have already said as to the possible fatality of all forms of angina.

Now for a few words as to treatment. If the attack is recognised to be of toxic origin the proper treatment is milk diet and removal of the cause (tabagic angina). The iodides are of great service, and, according to Gilbert, act as an antitoxic rather than as a resolvent in respect of the arterio-sclerosis. In any case, whether we are dealing with a grave or benign form of the disease, the lacto-vegetarian regimen is indispensable, the more so as it is extremely difficult to make out for certain whether there are or not co-existing coronary lesions.

Medicinal therapeutics will be guided by circumstances. If we are dealing with neurasthenic or hysterical patients we may employ suggestion and sedatives (bromides, valerian and antipyrine). We may prescribe the phosphates, the cacodylates, kola, with iron for anæmic patients. Alkalies and lithia are indicated in arthritic and gouty persons. In dyspeptics we must attend to the gastric functions. Organic lesions of the heart must be dealt with by the usual means—rest, milk diet, digitalis, &c. The same remark applies to renal disease and dyscrasic maladies. The thermal treatment is very efficacious in certain cases, not only by reason of the direct action of the waters, but also on account of the change of air, of habits, &c.

The attack in being must be treated by the administration of nitrite of amyl, drop doses of a 1 per cent. solution of trinitrine, subcutaneous injections of morphine, hot compresses over the præcordium, local counter-irritation, blisters, and the like.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of the journal. The lecture in next week's will be by Mr. A. B. Mitchell, F.R.C.S.I., Surgeon to the Royal Victoria Hospital, Belfast, on "Acquired Flat Foot."

ORIGINAL PAPERS.

TWO CASES OF APPENDICITIS DUE TO OXYURIS VERMICULARIS.*

By H. W. CARSON, F.R.C.S.ENG.,
Surgeon to the Tottenham Hospital.

THE first case was that of a single girl, æt. 19, who gave the following history:—She had had excellent health until one month before admission to hospital. She then had pain after food "like indigestion," and occasional vomiting during the last week.

On August 15th, early in the morning she was seized with violent pain in the right side of the abdomen, accompanied by vomiting. The vomiting continued during the day, but ceased at night, and did not recur. In the evening she was seen by a medical man, who reported a rapid pulse rate and a temperature of 103°.

On August 16th she had a rigor and was admitted to hospital.

Condition on Admission.—Temperature 103·8°, respirations 32, pulse 116. Patient anæmic; tongue moist, but slightly furred. She complains of severe pain and tenderness on the right side of the abdomen. The bowels were opened on the day before admission.

On Examination.—The abdomen moved with respiration, and was not distended. There was no rigidity of the abdominal walls. Superficial tenderness was marked over a large area of the right side of the

* Paper read before the Clinical Society of London, February 23rd, 1906.

abdomen, extending from the edge of the ribs to the iliac fossa, with tenderness in the right loin most marked above the crest of the ilium. There was much tenderness on deep pressure over McBurney's point. There was no swelling, but an area of dulness could be made out under the right rectus muscle extending two inches above and one inch below the level of the umbilicus. The rectum was full of *faeces*, but after these had been removed by enema nothing abnormal was found on rectal examination.

The heart and lungs were healthy.

The abdomen was opened and the appendix found to have a bulbous tip and slight recent adhesions between its proximal half and the cæcum. It was removed. The mucous membrane of the distal half inch was deeply congested, but not ulcerated. A single female oxyuris vermicularis was found in the congested area.

Subsequent History.—The patient at once lost all pain, and on the day following operation expressed herself as feeling quite comfortable. The temperature and pulse rate, however, returned to normal very gradually, the evening temperature reaching normal only on the ninth day. Repeated examinations of the lungs were made but nothing was discovered. The bowels were confined, but daily evacuations were obtained by enemata. The wound healed perfectly, stitches being removed on the ninth day, and at no time was there any distension or abdominal discomfort.

On August 30th, after the temperature had been normal for six days, the patient complained of headache and drowsiness. The temperature rose to 102.6° at 7 a.m., and was 104.4° at 7 p.m.; pulse rate 120. Examination of the abdomen and chest was negative. The temperature reached normal again on September 2nd, no physical signs having developed during this time.

On September 6th, the temperature rose again to 102.6° (7 a.m.), reaching 104.8° at 7 p.m., patient feeling drowsy, but otherwise not uncomfortable. Nothing was found to account for the temperature, which fell to normal on September 9th, and the patient left the hospital a few days afterwards. At no time during her stay in hospital did she pass any worms, and as far as she was aware she never had passed any. She writes to say that she has a "very sharp pain with the changes of the weather and cannot have action without medicine." She has not passed any worms.

The second case was that of a married woman, *æt.* 24, who gave the following history:—Her health had been good except for an attack of abdominal pain occurring one year before, which lasted for three weeks.

On November 29th patient was seized with a severe pain in the lower part of the abdomen, accompanied by slight vomiting. She was seen by a medical man, who diagnosed appendicitis and advised her removal to hospital. She was admitted on November 30th.

Condition on Admission.—Patient's general condition was good, but she was apparently in considerable pain. Tongue moist but slightly furred; temperature 100.6° , pulse 118 regular, respirations 28. The heart and lungs were healthy.

The patient complained of severe pain in the lower part of the abdomen, most marked in the left iliac fossa. The abdomen moved well with respiration; there was no rigidity of the abdominal wall, and no tumour could be felt. Percussion gave a tympanitic note. There was tenderness on deep pressure in the right iliac fossa, but this was at a lower level than is usual in appendix cases and resembled the tenderness occurring in pyosalpinx cases. *Per rectum* there was some general tenderness. *Per vaginam*, there was acute tenderness in both fornices but nothing abnormal was discovered, though bimanual examination was difficult owing to the pain elicited. There was not at the time, nor had there been, any vaginal discharge.

A provisional diagnosis of pyosalpinx was made, and as the patient was in great distress immediate

operation was decided on. The abdomen was opened in the middle line. The uterus and appendages were found to be normal, and the appendix was apparently normal. Mindful of the case three months before, I removed the appendix, and found three thread worms in the distal end of it. There was no injection or ulceration of the mucous membrane.

The temperature fell to normal on the evening of the day of operation, but the pulse rate was somewhat rapid for two days. Stitches were removed on the eighth day, the wound being soundly healed. At 11 a.m. on that day the temperature rose to 100.8° , with a pulse rate of 98. There were no symptoms and both temperature and pulse were normal next morning, but on the eleventh day after operation the patient complained of headache and abdominal pain, and the temperature rose to 102° , with a pulse rate of 112. Nothing could be found to account for this. The bowels were not confined. Next morning the temperature and pulse rate were normal again, and from that point convalescence was uninterrupted. She writes to say that about a month ago she had severe pains lasting about one week. She has not noticed any worms in her motions.

Both cases present certain features in common. In each case the patient was an adult woman in whom there had been no previous signs of thread worms. In each case the subjective signs were more marked than the objective, that is to say, that though tenderness and hyperæsthesia were well marked, there was no abdominal distension, no rigidity, no tumour. In both cases also the convalescence was interrupted by attacks characterised by elevation of temperature and pulse rate, and headache. Compared with ordinary cases of appendicitis, these two cases present certain unusual symptoms.

Onset.—The only point of difference with regard to the onset is, that in the first case a temperature of 103° occurred on the first day and a rigor occurred on the second day. As far as my experience goes a temperature of 103° on the day of onset is unusual, and the occurrence of a rigor at an early stage in appendicitis is quite a rarity.

Symptoms.—The most striking symptom was the degree of hyperæsthesia in both cases. In the first case the tenderness was limited to the right side, but extended far back into the right loin. In the second case tenderness was complained of in both iliac fossæ, worse on the left side, but the most acute tenderness was felt on vaginal examination, especially in the left fornix. Indeed, so much pain was caused that a thorough bimanual examination of the uterine appendages was impossible.

The general condition of both patients was also misleading. The first patient was apparently seriously ill, the temperature approaching 104° , with a weak pulse of 116. In fact, the case resembled one of those severe gangrenous appendix cases without marked physical signs such as one sees occasionally in children. The second patient, though not apparently so seriously ill, was in great pain, with a pulse rate of 118, and as this condition had lasted for 24 hours and was increasing in severity, it was looked upon as an indication for immediate laparotomy. In the second case there was a history of abdominal pain occurring a year before and lasting for three weeks, but whether this was appendicitis or not it is of course impossible to say.

Signs were practically absent in both cases. There was no abdominal distension, no rigidity of the abdominal wall, no interference with the respiratory movements and no tumour. In the first case an area of dulness was found under the right rectus at the level of the umbilicus, but this had no relation to the position of the appendix. Had one met with this hyperæsthesia with absence of physical signs in a child, especially if associated, as in the first case with a temperature of 104° I think one would have suspected that the case was one of pneumonia with abdominal

pain, but repeated examinations of the chest failed to find any pulmonary complications. The occurrence in both cases during convalescence of a sudden rise of temperature with headache is curious. It may, of course, have been merely a coincidence resulting from a sudden chill or a slight attack of influenza, or it may conceivably have resulted from the irritation of thread worms in the cæcum or colon, though no more were seen during the patient's stay in hospital or since. The after history of these two cases is unimportant, except that the second patient has had an attack of abdominal pain since leaving hospital which lasted for one week.

The question as to whether intestinal parasites do or do not cause appendicitis has given rise to very different opinions. On the one hand Dr. G. F. Still (1) quotes Heller as saying that there is no evidence that thread worms give rise to appendicitis; on the other there are a definite number of published cases in which thread worms have been found in diseased appendices. Metchnikoff (2) writes on "Worms as the cause of Appendicitis," and Von Noty (3) goes so far as to say that oxyuris and trichocephalus give rise to chronic appendicitis, while ascariides give rise to gangrenous appendicitis. There is no doubt that thread worms may exist in the appendix without giving rise to symptoms. Dr. Still (4) reports that in 200 necropsies on children under 12 he found the oxyuris in the appendix 25 times, and in 6 instances they were found in the appendix alone. In only one, apparently, were there any signs. This was the case of a boy of nine, who died of pericarditis, and in whose appendix 111 worms were found. He had complained of pain in the appendix region without tenderness.

I have been able to find only a few reported cases, where thread worms have been found in an appendix removed during life for the cure of appendicitis, and, unfortunately in only a few of these are any details of the symptoms given. All seem to be cases of relapsing appendicitis. Frazier (5) reported a case of a female, æt. 2, in whom there had been a five months' history of appendicitis. Thread worms were found in the appendix, without ulceration.

In the discussion which followed, Dr. H. D. Beyea gave details of the case of a married woman of 22, who had suffered for 2½ years, since the birth of a child, with back-ache, headache, and nervousness. Six weeks before operation she had severe pain, lasting for a week, in the appendix region; three weeks before operation a "convulsion" occurred, followed by others of an hysterical type. There was extreme tenderness but no tumour. A single oxyuris was found in the inner one-third of the appendix without hyperæmia. Erdmann (6) reported four cases containing between 6 and 30 thread worms. He gives no account of the symptoms. In *Pædiatrics* (May 15, 1900, p. 411) there is a report of a case occurring in a boy of 8, but no details are given. Guinard (7) reports a case of thread worms giving rise to symptoms which occurred in Routier's practice. A case is reported by Professor Bégouin (8) of a woman, æt. 24, who had had for four or five years attacks of right iliac pain occurring at long intervals, and lasting three or four days. There was a slight tender tumefaction, the size of an almond at McBurney's point. The appendix was slightly turgid; 15 thread worms were found with four small ulcerations. In the "Inter-Colonial Medical Journal of Australia," commented on by the *Lancet*, (1902, vol. 1, p. 539), Mr. R. Hamilton Russell reports the case of a boy in whom the chief symptom was severe pain. Some correspondence followed in the *Lancet* (1902, vol. 2, p. 58), and a case was reported by Mr. F. Bolton Carter (9) as having occurred at the Leicester Infirmary. The patient was a boy. In September, 1902, Mr. Jonathan Hutchinson, jun., (10) reported a case of a young woman operated upon for relapsing appendicitis in whose appendix many live thread worms were found. Morkovitch (11), reports a case of a man æt. 22, in whose appendix twelve live thread worms were found.

This makes a total, with my two cases, of 15, of which 6 were females, all, with one exception, young adults, 4 were males, all except one boys, and in 5 cases the sex was not stated. In the few cases where symptoms are given, severe pain and tenderness without local signs seem the rule, and in only one case was there any ulceration of the appendix. While it is certain that thread worms may exist in the appendix without giving rise to recognisable signs, it seems that we must believe either that thread worms may cause appendicitis or that the presence of the parasites is a pure coincidence. The latter theory is, I think, untenable, in view of the fact that the symptoms in these cases are much more severe than the lesions found would warrant, and I prefer to believe that thread worms may cause appendicitis, and that the attack is characterised by exaggeration of symptoms and absence of physical signs.

NOTES ON PSORIASIS.

By TOM ROBINSON, M.D.,
Physician to the Western Skin Hospital.

THE subject of these remarks is a malady in my experience second as regards frequency in those who attend the Western Skin Hospital. For I find that out of each 100 cases, not less than 9 have had psoriasis, whilst 13 were the subjects of eczema. Psoriasis is a malady which stands out as a distinct clinical entity. You will find, as a rule, that in large families it commonly—I was about saying usually—attacks only one member of the family. You may, and I believe you do, always find in any family from which a psoriatic person springs others who suffer from other cutaneous conditions, but I repeat it is common for only one person in a family to have psoriasis. The disease is never co-æval with, but appears, as a rule, about the age of 11 years; once and only once have I seen true psoriasis at 7 years of age.

The psoriasis spot, from its first appearance, is a papule which is scaly. To this rule there is no exception. You may demonstrate this fact in spots no larger than a pin's head. When the superficial scales are scratched off, we come down to a translucent membrane (*stratum lucidum*), and, when this is detached, bleeding points (the *papules*) are obvious; so that any papule which shows silvery scales when scratched with the nail or a knife, which has below it a semi-transparent membrane and bleeding points is a psoriasis. As the spots first appear we speak of the case as *Psoriasis punctata*. The spots increase rapidly in size until they become as large as lentils, resembling very closely mortar in colour. We then speak of the case as *Psoriasis guttata*. The two processes usually go on side by side, so we may be sure that when we find *Psoriasis guttata* we shall also find *Psoriasis punctata*.

The spots go on gradually extending from their circumference until they become as large as a florin, without undergoing any change; so that at this stage of psoriasis we find a number of spots varying in size,

*A Lecture delivered at the Western Skin Hospital.

and as their size varies we use a word to indicate their resemblance to a coin, *Psoriasis nummularis*.

When these spots increase in size they must of necessity come into contact with each other, and as others continue to make their appearance we find curious patterns. Thus, if three circles coalesce we see a trefoil pattern; in other cases a number of segments of circles will run into each other in such a manner as to produce different patterns, many of which have received fantastic names, such as *Psoriasis gyrata* or *Psoriasis orbicularis*.

Although we may find an enormous distribution of psoriasis, still we seldom—from my experience, I should say never—find a case of *Psoriasis universalis*. You will, I think, find in every case parts of the cutaneous area free from the characteristic eruption. A patch of psoriasis will grow at times until its diameter is quite two inches, usually it is much less. Long before it reaches such a dimension the scales in the centre commence being shed, and we find a ring-like appearance, the scales at the margin of the surface being raised and adherent (Willan described these cases as lepra). Following the natural course of a psoriasis spot, in some cases we find the eruption disappears spontaneously, leaving behind a reddened skin. This usually vanishes in time, and the skin assumes its normal aspect. Neither scar nor pigmentation remains after the disappearance of a psoriasis.

I think we always find more or less itching in cases of psoriasis, although a few patients will deny that there is irritation. We may demonstrate when itching is a predominant symptom, because the silvery crusts are interspersed with black or brown blood crusts.

The location of psoriasis presents some interesting problems. To assert that in every case of the disease we find the eruption clustered in greater abundance about the tips of the elbows and knees is misleading; because in some well-marked instances we have not found any spots in these situations, although there has been an abundant crop on other parts of the body. The eruption is seldom, if ever, seen on the palms of the hands or on the soles of the feet, nor commonly on the face.

The eruption is sometimes very limited in its distribution. Cases will be met with where well-marked spots of the malady will be found in such situations as the sacral region, the extension surfaces of the arms or legs, and the front of the thorax. These constitute some of the most obstinate cases we meet with.

The disease is common on the scalp, where it occurs in discrete spots. The hair is always influenced, being shed to a certain extent, and losing its lustre. Psoriasis of the scalp often spreads over the frontal bone and behind the ear. In these situations it loses its characteristic appearance, and is often cracked and formed like an old eczematous spot.

If we strip a case of psoriasis where the eruption is general, it will usually be found that the spots are larger and of a higher colour in the lower extremities than elsewhere.

Besides the eruption itself, in many cases the nails suffer from an altered appearance. The condition does not affect all the nails, neither is it symmetrical. The diseased nails are brittle, coarse on the surfaces, and look like cocoa-nut matting. We often find beneath the nail hid a spot of psoriasis which pushes up the nail, so that a probe may be passed beneath the nail without pain.

I have not time to enter into the question of the pathology of psoriasis. Unna strongly suggests that the disease is parasitic in origin. There is no evidence, to my knowledge, that psoriasis has ever been induced by artificial inoculation. Lang, of Innsbruck, claimed that he discovered a certain fungous element in the disease. I think we may rest satisfied in the knowledge that in cases of psoriasis there is an inflammation of the papillæ, and as a result of this inflammation we have an exaggerated epithelial growth which gives rise

to the varied canvas of the psoriatic process, a process which is unique.

Differential Diagnosis.—For usual clinical work we find in this hospital three diseases resembling psoriasis on first inspection, namely, pityriasis rosea, seborrhœa, and syphilis. Some would add lichen ruber.

If we remember that pityriasis rosea is practically limited to the trunk, that there is very little scaliness, and that the eruption vanishes in about eight weeks, we shall not fall into error.

There is much more difficulty in distinguishing between a general seborrhœa and a psoriasis. So much so is this the case that many dermatologists are of opinion that the two diseases are identical, one being an acute disease and the other chronic. There may be cases where the diagnosis is impossible between the two; if so, we have not met with them in the practice of this hospital. Seborrhœa is a much more acute malady than psoriasis. The particles of eruption have not the character of poisonous spots, and they yield much more readily to treatment.

It would require a thorough knowledge of the history of a case and a consideration of all the groups of symptoms to make a differential diagnosis between a scaly syphilitic and psoriasis, besides which, the scaly syphilitides do not advance in size like psoriasis; they are seldom more than half an inch in diameter. Sometimes we have been puzzled in late syphilitic manifestations because the *serpiginous* variety of the eruption, if not ulcerating, has in many instances a heaped-up edge which resembles the edge of a chronic psoriasis spot, but it is never a complete circle even when standing alone. It is invariably crescentic.

The cases which are most puzzling are those in which a syphilitic virus mingles with a psoriatic state. When this occurs we meet with an eruption which it is often difficult to designate—I was almost saying impossible—and most rebellious to treatment.

The Effect of other Diseases on Psoriasis.—If a patient with psoriasis contracts any of the acute blood diseases, the scaliness may entirely disappear. It will always do so, if the disease continues for any length of time. Should the patient recover, the psoriasis always reappears. It is well to be acquainted with this fact, otherwise we may lead our patient to believe he has got rid of his trouble. In point of fact, any conditions of health which cause depression of the vital force will cause a diminution of the psoriatic eruption. This is notably observable in some cases of pregnancy.

On one occasion a *post-mortem* was made by the late Dr. Sutton in the London Hospital on a man who had died with double pneumonia. He had a very copious psoriatic eruption. The usual appearance of psoriasis had disappeared. The scales had, to a large extent fallen off. The red patches which support the scales had paled until they nearly resembled the adjacent skin.

Treatment of Psoriasis.—However great the interest of the study of disease may be—and it is, indeed, a fascinating process—our patients will stand before us and ask this very awkward question: "Can you cure me?" It is best to answer with absolute frankness, and say: "In our present knowledge of psoriasis we can promise to get rid of the eruption, if you will persevere with your treatment; but we must warn you that in all probability your eruption will reappear at some future time." I am afraid we cannot say more.

We have next to ask ourselves what is the best treatment to follow. We may, I think, lean upon three internal remedies—arsenic, salicylate of soda, and thyroid extract. It will be some guide if you will remember that you will probably succeed best with arsenic in those cases which have been in existence for some years, and especially cases where the spots have not grown to any great size. I am not able to prove to you that arsenical solution is in any way inferior to the arsenic pill, but I use in my own practice the latter, and I am satisfied with the results. The pill consists of 1-20th of arsenic, 1 gr. of black

pepper, and 1 gr. of sulphate of iron. In most cases it is sufficient to give three pills a day; but in other cases, where the disease is obstinate, it may be increased. I cannot remember any cases where the drug has proved pernicious in its effects. We need not fear any accumulation of poisons in the organism. Hebra asserts he has given as much as 160 grs. of arsenic (?) acid in one case. In recent cases of psoriasis we find 5 grs. of salicylate of soda apparently of efficacy.

The cases of psoriasis which are influenced in quite a remarkable manner are those which exist in women at the menopause. At this period of a woman's life, when there is a deposit of fat in the tissues, either myxoedema or an analogue of that disease, a tablet of thyroid extract given three times a day will produce a change in the whole organism, and in the psoriatic spots.

We will now discuss the external treatment of psoriasis. On the remedies applied to the skin we must depend to get rid of the manifestation of the disease. The first object must be, to get rid of the scales. To accomplish this, wet packing, if possible, is by far the most efficacious. But it is tiresome, and means confinement in bed.

For practical purposes the immersion of the body in baths at a temperature of 100°, with the free use of pine soap, will clear off a quantity of the scales. After the bath the patient should have rubbed into every spot an ointment composed of equal parts of tar, ammoniated mercury, and salicylic acid ointments. When the psoriasis appears on the scalp, we get good results by a vigorous washing of the scalp with soap and afterwards rubbing in the ointment already mentioned, omitting the tar.

CLINICAL RECORDS.

A CASE OF ADVANCED CARCINOMA OF BOTH OVARIES.*

By HY. JELLETT, M.D., B.Ch., F.R.C.P.I.,
Gynaecologist and Obstetric Physician to Dr. Steevens' Hospital.

A patient, æt. 40, was admitted to Steevens' Hospital on August 17th, 1905, complaining of a gradually increasing swelling in abdomen, with occa-

FIG. 1.—Carcinomatous tumour of Right Ovary.

sional attacks of violent pain. She had been in good health up to Christmas, 1904. The menstrual periods were regular, lasting four days, and were preceded by pain. She was married four years ago, and first noticed

* Read at meeting of British Gynaecological Society, March 8th, 1906.

a swelling in her abdomen at Christmas, 1904. At first there was no pain, but latterly violent paroxysmal attacks came on which were temporarily relieved by treatment. On examination the lower abdomen and pelvis were occupied by a hard irregular-shaped mass, found adherent to pouch of Douglas, and to uterus in front so as to suggest malignant disease of ovaries. It was decided to make an exploratory incision five days after admission, when the mass was found to consist of two separate tumours in pelvis, presenting the appearance of glandular cysts of both ovaries being adherent below but free above. The abdominal opening was enlarged by a transverse incision through the left rectus out to the left anterior superior iliac spine. The tumour on the left side was removed without much difficulty; that on the right was more adherent and consequently removed with considerable difficulty. An abscess was found between the tumours, and there was extensive infiltration of the ligaments so that the uterus had to be removed at the same time. The uterus was removed between clamps passed up from the vagina and the pelvis packed with iodoform gauze, which was drawn through the vagina.

FIG. 2.—Tumour of Left Ovary shown in cross Section

The adhesions between the tumours and the pelvis were very vascular, so that the patient lost a considerable quantity of blood. She, however, rallied well. The plug and clamps were removed three days later and the patient subsequently returned home with three small sinuses in abdominal wall. Four months later the patient returned to hospital when the sinuses were still found open. These sinuses were scraped with a sharp spoon and some sutures were removed, and iodoform emulsion poured into the cavities. They then closed completely. On examination of the rectum, at the same time, it was found to be surrounded by a hard mass which is presumably further infiltration by the growth. The patient however, has increased in weight and appears well.

The report of the pathologist on the tumour was that the solid growths consisted of carcinoma of irregular-celled type, and that the ovaries likewise contained glandular cysts.

CASE OF DOUBLE PYOSALPINX ASSOCIATED WITH THE PRESENCE OF A FOUR MONTHS EXTRA-UTERINE FÆTUS.

By HY. JELLETT, M.D., B.Ch., F.R.C.P.I.,
Gynaecologist and Obstetric Physician to Dr. Steevens' Hospital.

The patient, æt. 27, was admitted on September 16th, 1905, complaining of bleeding during coitus, pain in lower abdomen and back. Menstrual periods were too frequent, and the discharge was offensive. There were

no children, but patient said she had had a miscarriage at about the eighteenth or twentieth week eighteen months previously. On examination, an erosion of the cervix was found which bled freely.

Four days after admission, on making an examination under an anæsthetic, the uterus was found to be retro-deviated and drawn to the right. A hard, irregular mass about the size of a hazel nut was detected in the region of the right ovary, which extended outwards to the wall of the pelvis. The appendages on both sides were considerably enlarged. The uterus was curetted, and a portion of the erosion removed for examination.

About one month later, on opening the abdomen, the omentum was found thickened and adherent to the

FIG. 3.—Double Pyosalpinx and Skeleton of Extra-Uterine Foetus. (A) Right appendages. (1) Site of attachment of fetal skeleton. (2) Right Ovary. (B) Left Fallopian Tube. (C) Foetal Skeleton.

Fallopian tubes. The right tube was enlarged to the size of a sausage, distended with pus and bound up with the ovary. The skeleton of a four months' foetus projected from the ampulla. The left tube was dilated to the size of a finger and contained pus, while the left ovary was cystic. Both tubes and right ovary were removed. Vento-suspension of the uterus was performed after Kelly's method. The sutures were removed on the eighth day with the exception of one which broke and left a piece about three inches in length behind. The patient was discharged in three weeks. In three months she presented herself for examination, when the uterus was found in good position and convalescence established.

The pathological report on the portion of cervix removed stated that the erosion was covered with squamous epithelium, being very vascular, and infiltrated with small round cells. The scrapings from the uterus showed columnar epithelium on surface, increased number of glands, and extravasation of blood interstitially as in glandular endometritis.

St. George's Hospital Medical School.

We are asked to announce that a private subscription dance in aid of the endowment fund of the Medical School attached to St. George's Hospital will be held at the Hotel Metropole, on May 2nd, under the patronage of H.R.H. the Princess Christian, the Duchess of Bedford, &c. Tickets for the dance (including champagne supper), £1 5s., can be obtained from the patronesses, or from Mrs. Humphrey Rolleston, 55, Upper Brook Street, and Mrs. G. R. Turner, 41, Half Moon Street, London, W.

THE OUT-PATIENTS' ROOM.

METROPOLITAN HOSPITAL.

Graves' Disease.

By LEONARD WILLIAMS, M.D., M.R.C.P.

DR. LEONARD WILLIAMS made the following remarks on the case:—

This woman is suffering from exophthalmic goitre. This may seem somewhat surprising, for she has no exophthalmos, nor has she any goitre. These two symptoms are, however, by no means essential to the diagnosis of the condition, which is, for this and other reasons, better called Graves' disease. Some people lay great stress on certain eye symptoms in Graves' disease, such as Von Graefe's sign and Stellwag's sign. These two are, in reality, quite valueless as soon as the existence of exophthalmos has been established, because they are both of them entirely dependent upon, and are produced solely by, the protrusion of the eyeballs. Von Graefe's sign is that the upper lids tarry in their descent when the patient looks down, Stellwag's sign is the widening of the palpebral fissures. A moment's consideration will show that these two follow inevitably if there is, as it were, a force inside the cranium which pushes the eyeballs forward against the lids. Von Graefe's and Stellwag's signs are, therefore, unable to help us when exophthalmos is absent, and when it is present we can make our diagnosis without their assistance. There are, however, two ocular phenomena which are of real value in doubtful cases. One is definite diminution of the conjunctival reflex, which this patient has; the other is ptosis of the right eyelid. The latter is a curious sign which is seldom present, partly because it is rare and largely because it is transient. It does not generally last longer than a day or two at a time. It may affect the left lid, for aught I know, but in my own cases it has always been the right. The absence of thyroid enlargement is important. The gland is generally enlarged, frequently unilaterally, but the absence of any enlargement must not lead one to suppose that the case is therefore not one of Graves' disease. The presence of an enlarged thyroid to the exclusion of other obvious symptoms (exophthalmos, for example), is even more important, because if the physician forget that a goitre may exist for years without other obvious signs, he may be tempted to hand his patient over to the tender mercies of the surgeon with results which all parties will have cause to regret, because these people bear operations very badly.

Exophthalmos and goitre are, therefore, unreliable symptoms so far as diagnosis is concerned. If they are present, even in slight degree, they are both immensely helpful, but if either or both are absent the case may still be one of Graves' disease. There are, however, two symptoms upon which one can rely, namely, tachycardia and tremors. This patient has both in a very pronounced degree. Her pulse is 125, and on extending her arms and spreading out her fingers, you see that very decided coarse tremors are developed. The tremors in these cases are seldom coarse. They are, indeed, as a rule, so fine that it is easier to feel them than to see them. If the medical man place his finger-tips on the backs of the outstretched hands, he will often become conscious of tremors, very rapid and very fine tremors, which his eyesight may have failed to detect. Tremors are very characteristic of this disease. And not physical tremors only. These people suffer from a species of mental tremor, inasmuch as they are nearly always in a state of suppressed excitement. Not a few of them ultimately develop definite forms of mental alienation, especially women at or about the menopause. There are a great many other symptoms which may be expected in a case of Graves' disease, but I want to emphasise the fact that if the physician find a combination of tachycardia and tremors in a patient (even if that patient be a man), he should always be on his guard, for in ninety-nine cases out of a hundred he is in the presence of a case of

exophthalmic goitre. There is only one drug which has ever seemed to me to do much good in these cases, and that is belladonna. It frequently does a great deal of good, but, as frequently, it fails. Hygienic treatment is very important. If possible, these patients should be removed from large towns into quiet country districts where the wheels of being can be made to move slowly. Bracing climates are very injurious, so are stimulating foods. Meat should be deleted from the dietary and all forms of excitement or fatigue forbidden. Tepid salt water baths are very useful, especially when combined with gentle massage. Parents and friends should be told not to thwart or irritate these patients. This is in reality a counsel of perfection, because if sufferers from this complaint have no legitimate grievance they will always manufacture an imaginary one. They are generally very unreasonable.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

AN ACCUMULATION OF FLUID IN THE PROCESSUS VAGINALIS SIMULATING A RECURRENCE OF INGUINAL HERNIA AFTER A RADICAL CURE.—MR. WILLMOTT EVANS operated on a case of apparent recurrence of inguinal hernia after radical cure. The patient was a man, *æt.* 23, who had suffered from an inguinal hernia on the right side a few weeks after birth, and when *æt.* 8, a radical cure had been performed by another surgeon. From that period till a year before the present time he had been free from any sign of return of the disease. Within the last few months, however, he had noticed a gradually increasing prominence in the right inguinal region, and on account of this he sought relief. On admission he had in the right groin an oval swelling about the size and shape of a hen's egg; it was situated just below and internal to the external abdominal ring, and its long axis was directed downwards and inwards; it was soft on palpation, and gave an indistinct sensation of fluctuation; on coughing no well-defined impulse could be felt, and the swelling was only partly reducible; it gave rise to no pain and but little inconvenience, but the patient wished to have an operation performed to relieve him of it. An oblique incision through the skin was made over the long axis of the swelling and the tissues were dissected carefully until the "sac" was reached. When this was cleared from surrounding structures, it was evident that it passed from the external abdominal ring to the upper part of the testis. As the contents could not be returned into the abdomen, the "sac" was opened, and it was found to consist of a thin-walled cavity not communicating with the general peritoneal cavity, but formed of the remains of the unobliterated processus vaginalis. On making traction on the wall of the cyst the contents of the inguinal canal were brought down and it was clear that the "sac" was a constituent of the spermatic cord. The "sac" was ligatured at its upper part, and again just above the testis, and the cyst removed. The wound was closed and dressed. Mr. Evans said that it seemed to him clear that the condition which had been found was due to an accumulation of fluid in a processus vaginalis which had been obliterated near the internal abdominal ring and also just above the testis, but the intermediate portion had remained open; in fact, the condition was structurally identical with that known as hydrocele of the spermatic cord, but in this case the closure of the processus vaginalis was due to surgical interference. In his opinion, what had happened was this: At the operation fifteen years previously, the funicular process had

been ligatured as high up as possible, but apparently no attempt had been made to remove the portion of the processus vaginalis which lay in the spermatic cord. The processus had spontaneously become blocked immediately above the testis, but not elsewhere, with the result that fluid had accumulated in the unobliterated portion. So far as the cure of the congenital inguinal hernia was concerned from which the patient had suffered, it must be acknowledged, he said, that it was successful, but the moral of the case was, he thought, that it was not sufficient merely to tie the funicular process at its upper extremity or even just above the testis also, but it was desirable to dissect out all that portion of the processus which had no permanent function. The operation of the radical cure of congenital inguinal hernia in childhood, he pointed out, was so simple and so easily performed that the slight lengthening of the proceedings by removal of the processus from the cord could not be considered to increase materially the risk of the operation. The situation and the characters of the swelling pointed strongly to some form of recurrence of the hernia, but the present operation demonstrated that the hernia had indeed been radically cured.

Except for a slight collection of blood in the wound, the patient made an uninterrupted recovery.

ITALIAN HOSPITAL.

SQUAMOUS EPITHELIOMA.—MR. LENTHAL CHEATLE operated on a man, *æt.* 54, the subject of a squamous epithelioma on the edge and somewhat on the dorsal surface in the middle of the anterior two-thirds of the right side of the tongue. The patient was anæsthetised and the neck purified. An incision was made from the mastoid process to the sterno-clavicular articulation. The lymphatic glands in the anterior triangle were removed, the lingual and facial arteries were ligatured. A curved incision was then made in the skin from the symphysis of the lower jaw to join the first incision. The submaxillary, salivary, and lymphatic glands were removed, and also the submental lymphatic glands. The mylo-hyoid muscle and the anterior belly of the digastric muscle were retracted upwards and forwards. The posterior belly of the digastric muscle with the stylo-hyoid muscle were retracted backwards. The attachments to the hyoid bone of the hyo-glossus, genio-hyo-glossus, and inferior lingualis muscles of the right side were then cut away quite close to the bone. The stylo-glossus muscle was cut far back as it left the styloid process. The lingual artery and vein were divided and pushed upwards with the divided muscles, but otherwise left in their normal conditions. The rest of the right side of the tongue was then removed by cutting the tongue in half and cutting the mucous membrane away from the mouth by scissors. Mr. Cheatle said that the patient whose right side of the tongue had just been removed had been prepared for the operation in two ways—(1) decayed stumps had been extracted and his teeth thoroughly scrubbed and cleaned for a week beforehand; (2) he had been injected with a dose of dead staphylococci, and his opsonic index tested by Professor Wright's method, and his operation was performed when the index was high and not in the negative phase. The attempt to render him immune to staphylococcus was made because in examination of the discharge in two previous cases after excision of the tongue, staphylococci were the only micro-organisms present. Mr. Cheatle remarked that he quite saw it might be advisable to render the cases immune against other micro-organisms as well as staphylococci, but the matter required

further work and study. But the post-operative results when working against staphylococci only had been very encouraging. The next point to which Mr. Cheatle referred was the question as to when one ought to limit the operation to excision of half the tongue. It was by no means an easy question to answer. But, roughly speaking, he always adopted the following plan:—By two imaginary longitudinal lines he divided the half of the tongue in question into three imaginary spaces. If the cancer occupied the outermost space, only half the tongue could be safely excised, and even if the middle space were invaded half could be excised; but if the internal space were involved then the whole tongue must be removed. In the present case the cancer involved the outermost space, so it was quite safe to attack the corresponding half only. Mr. Cheatle pointed out that the method of attacking the tongue from its attachments to the hyoid bone was based upon the following observations made by him. He found that in many cases which died soon after operation for excision of the tongue secondary deposit was left behind in the hyo-glossus muscle, in the glossal fibres of the genio-hyo-glossus and also in the fibres of the inferior lingualis muscle. Although he cut the stylo-glossus muscle far back in this case, he has not found any secondary deposits in this muscle. Another reason for paying particular attention to these muscles individually, he pointed out, was the fact that primary growth of the cancer spreads in them and the formation of the primary growth corresponds to the size and shape of these muscles. The cause of this fact he put down to trophic influences. He drew attention to the further fact that the extent and depth of the downgrowth were often greater than the area occupied by the malignant ulcer on the tongue's surface; another fact supporting the view that trophic influences were inducing a greater spread of the growth in its depth than at its surface. Further, there are often absolute middle-line limitations of cancer of the tongue at its surface that, he believed, could only be explained by a neuro-trophic limitation as there is no mechanical or lymphatic causes that might account for it. The median septum does not reach the sub-mucous tissue, but ends in the muscles of the tongue.

SPECIAL ARTICLE.

UNIVERSITY EDUCATION IN IRELAND.

[FROM A CORRESPONDENT.]

WHEN Irishmen with a natural love of contention are provided at one and the same time with three such bones as education, politics, and religion, it is only natural to expect that the outside public will be invited to witness the strife. This is exactly what is happening in Ireland at the present moment. On March 7th, the Senate of the Royal University met and passed the resolution which we published in our last issue, calling attention to the necessity for reorganising the Royal University in such a manner as to constitute it a teaching body. On March 9th, His Grace, Archbishop Walsh, made at a Dublin Hospital meeting a serious attack on the School of Physic of Trinity College, Dublin. This attack was based upon sundry reports of inspectors sent by the General Medical Council to inspect the examinations of the School, and we think that we are not representing it unfairly when we say that it dwelt on every unfavourable criticism that could be found, and neglected all others. On Wednesday, March 14th, the Council of the Royal University Graduates' Association met in Belfast and adopted a series of resolutions which we publish in our present issue, condemning lock, stock, and barrel the resolution of the Royal University. On Thursday, March 15th, appeared in the daily press a letter from Professor Francis Dixon, University Professor of Anatomy in Trinity College in defence of his school. We trust that all those who have read Archbishop Walsh's speech at St. Vincent's Hospital will now in turn read the letter of Professor Dixon. The latter is studiously moderate in his tone, wonderfully

so, many people will think in face of the provocation he has received.

As a medical man and a graduate of Dublin University, the writer does not desire to enter into such controversies. He has also had numerous opportunities of making himself familiar with the manner in which examinations are conducted in three of the four licensing bodies in Dublin, but, from that very fact he is debarred from entering into details.

The impression that is left upon his mind by His Grace's speech is that, for some purpose best known to himself, His Grace has decided to ride for a fall in the eyes of those who are familiar with examinations in general and who know the opportunities which the reports of inspectors offer for *ex parte* criticism. He also appears to voluntarily ride for a fall in the eyes of those who, knowing nothing of examination method, yet know something of the principles of fair comment. It is inconceivable that an able and most highly educated gentleman could suppose that either of these two classes could be influenced by such a speech, save, perhaps by its element of ridicule. The one class knows that not alone was there never yet an educational body that escaped comment at the hands of outside inspectors, but that every medical licensing body in the United Kingdom could be criticised with equal facility were similar methods adopted; while the other class knows that fair comment is hardly couched in the form adopted by His Grace, and that, when only praise of one examining body and only blame of another are brought to light, there must be omissions and there must be animus. Can it be that His Grace intended his speech, not for his educated listeners, but for the larger democratic body to whom its suppressions and inaccuracies will not be apparent?

No one, and certainly least of all the writer, will deny that there are faults in the examinations of Trinity College. Every educational body has its faults, and many of these were noted and adversely criticised by the *inspector*—for on the last occasion to which Archbishop Walsh refers there was but one, and we regret to say that the medical profession has since been made the poorer by his death. At that inspection, although he was a most able inspector, several criticisms were made through a misconception either of methods or of facts. He was at the time placed in the difficult position of discharging the duty of an absent colleague as well as his own, and, possibly, in the hurry of discharging both, mistakes occurred. Were he alive and free to express his opinions, we doubt if His Grace's deductions would be allowed to pass uncorrected.

To the writer, as an outsider, there is a sad point in the affair that has been overlooked. Do such attacks by Irishmen on Irish Institutions redound to the credit of Irishmen? What would be thought of an Archbishop of Canterbury, if perchance he was a graduate of London University, had he gone to a London hospital and criticised the Oxford Medical School with a spirit and a purpose similar to that of His Grace of Dublin? Had he looked over the reports of the Inspectors on that School, he would have found his material. Nay, had he turned to the report of any examining body he would have found sufficient material for a similar purpose. What would have been said of the Provost of Trinity College, if he had made a visit to the Adelaide Hospital an occasion for a vitriolic attack on the School of Medicine of the Catholic University, and took for his text any of the slips or accidents which may take place in that excellent institution, as in any similar institution, from time to time? We venture to say that such attacks would have met with the condemnation not alone of the friends of the Bodies into which the attackers stuck their verbal darts, but by their own colleagues.

His Grace uses dangerous weapons. Were Trinity College what he painted it, they might return to him poisoned, instead of as Professor Dixon has handed them back.

[We shall be glad to publish any further expressions of opinion on this important subject.]

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, FEBRUARY 16TH, 1906.

SIR THORNLEY STOKER, President of the Academy, in the Chair.

ABDOMINAL AND PELVIC TUBERCULOSIS.

DR. LITTLE, having briefly referred to some elementary facts in connection with the pathology of tuberculosis, discussed the symptomatology and treatment of tuberculous disease as it affected the peritoneum, the intestines and the mesenteric glands.

SIR WILLIAM SMYLY said that the study of tuberculosis of the female genitals during life has only been rendered possible since the use of the curette and abdominal section have come into vogue. The Fallopian tubes are the organs by far the most frequently affected, the uterus fairly often, other parts but rarely. The most interesting points connected with this subject are the possibility of infection through spermatic fluid, and also the infection of the fetus by its mother. The difficulties attending diagnosis are so great that until the parts have been examined by the microscope it can rarely be attained with certainty. Neither the shape of the tumours, nor the thickening of the uterine end of the tube, to which so much importance has been attached by Hegar, nor the nodules on the folds of Douglas, being peculiar to this disease. As regards treatment, the removal of the diseased organs is an operation amongst the most difficult and dangerous in surgery, and not infrequently leaves the unfortunate patients with incurable fistulae.

Professor McWEENEY referred at first to his experience with regard to the urine in cases of genito-urinary tubercle. He found tubercle bacilli without difficulty in about 90 per cent. of purulent urines, with a distinctly acid reaction. The tubercle bacilli are usually agglutinated, owing to the saline concentration of the urine, and accompanied by polynuclear pus cells, owing, no doubt, to liberation of their proteins by osmosis or plasmolysis. He next dealt with the hypertrophic variety of tuberculosis of the ileocolic region of the bowel, and exhibited naked eye and microscopic preparations illustrating its morbid anatomy. He emphasised its resemblance to cancer and its manifold differences from the ordinary tuberculous ulcerations; met with in consumptives who swallow their sputum. He suggested that it might be due to ingestion of bovine bacilli. Finally, referring to the results of the most recent work in this department, he observed that Behring's belief in the intestinal origin of pulmonary consumption had received confirmation at the hands of Calmette, of Lille, and his pupils, who found that pigment ingested by adult animals found its way at once to the lungs, whilst in young animals it was at first stopped in the mesenteric glands. Calmette had, moreover, succeeded in producing pulmonary tuberculosis, without lesion of the gastro-intestinal *mucosa* or of the mesenteric glands, by introducing suspension of tubercle bacilli into the rumen of adult goats. These results, if confirmed, together with the disproof of Koch's assertion—that bovine bacilli are innocuous for the human race—should put us more on guard than ever against the dangers of infected ingesta.

Mr. T. E. GORDON said that there had not been any notable advance in the surgery of abdominal tuberculosis during recent years. Laparotomy was frequently successful in curing the ascitic form of tuberculous peritonitis, but was not invariably so—perhaps it was less frequently successful than generally supposed. In the fibrous form the results of operations were almost uniformly bad, except in cases of well

localised abscess; even in these an intestinal fistula was likely to result. It seems reasonable to hope that some of these cases of fibrous and caseating tuberculous peritonitis will be cured by tuberculin.

Mr. GORDON read an account of a case of chronic abscess successfully treated by tuberculin (Dr. Gunn's case). When extensive adhesions have formed, the cure by tuberculin or any other treatment cannot be complete, for matted intestines are in themselves a source of distressing symptoms and danger. Speaking of tuberculous growths in the intestine giving rise to fibrous overgrowth and causing chronic obstruction, Mr. Gordon related the case of an old man for whom he had short-circuited a portion of ileum with temporary success. Some months later the man returned to hospital with fresh obstruction and died. At the autopsy no less than five different tuberculous masses were found in different parts of the small intestine. It seems clear that tuberculin treatment can never replace surgery in cases of this type, but it seems possible that by its use, as an after-treatment, what was only palliative may become curative. The speaker had not himself met with a case of tuberculous appendicitis. He had seen a case of tuberculous stomach ulcer, and he suggested that some of the cases of chronic ulcer with marked fibrous thickening, which are now regarded as simple, may prove to be tuberculous. Mr. Gordon concluded by saying—"Looking forward we may, with reason, hope for better results (in tuberculous disease of peritoneum and intestine) aided by tuberculin. Still it seems improbable that here the new treatment will have its greatest triumph, for neither in fibrous peritonitis nor in intestinal obstruction can it be expected to remove the mechanical disablement caused by the tuberculous disease."

Professor WHITE dealt with Wright's recent work, and stated that the good effect of operations in certain cases of tuberculous peritonitis depended mainly on two factors—the first being the replacing of a fluid containing little or no protective substances by a fresh fluid containing a much larger amount, and the second being the rise in the opsonic index due to auto-inoculation which results from operation. He illustrated both factors by several curves of the opsonic index in cases of a tuberculous nature which had been operated upon. He also demonstrated a fall in the opsonic index in four cases of tuberculous peritonitis which had relapsed, and in the only case which he had examined where the patient remained well the opsonic index was above normal. He considered that in future the treatment of tuberculous peritonitis would consist in raising the index prior to operation, and, subsequently, after the effect of the auto-inoculation produced by the operation had passed off, in keeping the opsonic index high, by suitable interspaced inoculations, until the local condition was quite healed.

Dr. PARSONS drew attention to the occurrence of tuberculosis in hernial sacs, and said he had a patient suffering from that affection who showed no signs of abdominal tuberculosis. He recently saw an account given, by Dr. Carmichael, of 154 cases of hernia in children. Four of these were tuberculous, and in one of the four there was found general infection of the abdominal cavity.

Dr. COLEMAN said he thought that both the diagnosis and treatment of tuberculosis had been placed on a very satisfactory footing by Wright's method. Wright had treated severe cases of tuberculous peritonitis with success. That method, however, was not suited for every case.

Dr. PUREFOY said he saw tuberculous conditions of the genital tract in two puerperal cases. Both patients died a few weeks after delivery of advanced pulmonary phthisis. One of these had borne several children.

In her case he found projections, like yellow pustules, on the posterior vaginal wall. One case of tuberculous nodules on the uterine end of the Fallopian tube has been reported.

Sir THORNLEY STOKER said that Dr. Coleman seemed to be curing by Wright's method patients that he had failed to benefit by operation. Two years ago a patient came to the Richmond Hospital with a tumour in her right iliac region. He explored it, after incision, and found a hypertrophic tuberculous mass in the ascending colon, which he removed. The patient never got a rise of temperature, and left the hospital well.

Mr. J. M'ARDLE said, in reference to tuberculosis in a hernial sac, that where a hernia had been present for some time the intestinal wall was weakened, and it was this condition that allowed the tubercle bacilli to permeate it. As to the possibilities of the tuberculin treatment, we were now employing no haphazard method. He did not think, however, that we had yet got a panacea for the lesions caused by the tubercle bacillus.

Dr. TRAVERS SMITH said in his clinical experience diarrhoea was not a constant symptom of tuberculous ulceration of the intestine. Dr. Earl made a *post-mortem* examination of a boy, æt. 14, who died from pulmonary tuberculosis, whose large and small intestine were extensively ulcerated. He also expressed surprise at Professor McWeeney's statement that 90 per cent. of acid urines containing pus were tuberculous.

Mr. E. H. TAYLOR mentioned the case of a man who came to hospital about a fortnight ago with pain in the abdomen and swelling in the right side. Opening the abdomen, he found a tumour as big as an orange in the ascending colon, above the cæcum. The muscular coat of the ileum was hypertrophied, and some of the neighbouring glands were caseating. We regarded it as tuberculous. After operation the patient got well.

Dr. MOORHEAD spoke of a case of hypertrophic tuberculosis of the cæcum, which had been remedied by complete excision of the cæcum and ileum.

Dr. LANGFORD SYMES said tuberculous ulceration of the genital tract, even in children, was said to have occurred. There was a variety of tuberculous peritonitis in children in which infection was brought about by means of the umbilical cord. The abdomen was enormously distended by gas, the child wasted considerably, but there was no ulceration of the bowel. Extensive miliary tubercles were present. A foul and fetid discharge from the umbilicus in young children was connected with tuberculous affections.

BRITISH GYNÆCOLOGICAL SOCIETY.

SPECIAL MEETING HELD MARCH 8TH, 1906.

MR. BOWREMAN JESSETT, President, in the Chair.

The resolutions carried at the special meeting of the Society held on February 8th were unanimously confirmed, and the Articles of Association of the Society altered by adding the following resolutions:—“(1) That in the event of any vacancy occurring amongst the officers of the Society or in the Council, by death, resignation, or in any other manner, the Council shall have power to fill such vacancy from amongst the Fellows of the Society. And any Fellow so appointed by the Council shall hold office until the next Annual meeting. (2) That in view of the proposed amalgamation of London Societies recently brought before this Society and approved of, ‘The Examination of Nurses be discontinued.’

The ordinary monthly meeting of the Society followed.

Dr. JELLETT showed specimens (1) Advanced carcinoma of both ovaries, and (2) Double pyosalpinx, associated with the presence of a four months' extra-uterine fetus, which will be found, with illustrations, on page 307.

The PRESIDENT said they were very much indebted to Dr. Jellet for showing these interesting specimens. He considered the operation in the first case was undoubtedly justifiable, and the result proved it to be so. He asked whether there was any glandular mischief present?

Dr. C. H. F. ROUTH said the first case exhibited the finest technique. No man who thoroughly understood his work could have dealt with the case otherwise than had been done. He maintained that the operation was perfectly justifiable. If a patient was certain to die without an operation, he considered one ought to operate as the only hope of saving life. He had seen cases admitted as hopeless, and yet after being operated on complete recovery ensued. He remembered one case at a general hospital, where five members of the staff gave their opinion that it was inoperable, while he advocated operation; the advice was acted on, and the patient recovered.

Dr. SLIMON asked whether a transverse incision was absolutely necessary; also whether ventral suspension in the second case was necessary.

Dr. MACNAUGHTON-JONES, in showing some specimens illustrative of Dr. Jellet's case, said that he had no doubt as to the justification for this operation. In one of his cases (ovaries shown) the patient weighed only five stone before operation—one ovary was converted into the huge carcinomatous mass (shown) the other was a large fibro-adenoma—the patient was in as bad a state as she could be. She grew strong after the operation, but about six months after she died of obstruction of the bowel, which was due to secondary infection of the bowel. In the other case the two large cysts (carcinomatous ovaries, shown) were removed, and the two myomata enucleated, when the patient was in a very hopeless state, but she made an excellent recovery and lived for over a year, the disease, as in the last case, recurring in the bowel. He showed an adeno-sarcoma of the ovary recently removed from a patient æt. 62, who was doing remarkably well. A few practical points in relation to these cases were worth remembering. First, that in bimanual examination under an anæsthetic, if too much force be used the cysts, adenomatous, sarcomatous or carcinomatous, were apt to be ruptured, and if not immediate peritonitis, secondary metastatic infection might follow. He had known this occur rapidly in one case. Secondly, many of these carcinomatous and sarcomatous ovaries caused so little pain that the presence of malignancy, or indeed of anything serious being wrong, was not suspected until a short time before operation, and, in the absence of any constitutional signs, malignancy was not suspected or discovered until operation. In regard to the ectopic gestation, he fancied the salpingeal trouble preceded the gestation.

Mr. RYALL remarked the case was one of double cancer of the ovaries and the after-history would be interesting. As far as peritoneal infection was concerned he did not believe it was so serious to damage a malignant ovary during operation. It was not as serious as breaking into a malignant growth in other organs. A short time ago he operated upon a case of malignant ovary. At first he thought it was a simple cyst. The patient had also a mass in the pylorus, and it was just an ideal case for pylorotomy, but she had many other growths elsewhere, therefore nothing further was done. She died about a month later as the result of abdominal invasion.

Dr. HODGSON said he did not think there could be any doubt about the advisability of operating on a patient who was about to die if there was any chance of benefit resulting.

Mr. H. OVERY said the second case was one of incomplete abortion. The interesting point to him was its etiology. It seemed that the pyosalpinx was probably subsequent to the extra-uterine foetation. He asked whether there was any history of discharge from the vagina during the latter months. There was no doubt that a tumour might subsequently become

malignant. Recently he did a *post-mortem* examination and on opening the abdomen found a large ovarian cyst, apparently a simple one, but one part of it had become malignant and was attached to the bowel. The bowel was invaded and intestinal obstruction had taken place. The carcinoma was probably a primary one of the ovary and not of the bowel. There was no doubt that an ovarian cyst might become malignant later.

The PRESIDENT thought the opinion that operation was not justifiable in these cases to be untenable. He knew several cases in which the patients who were practically dying had been operated upon and lived for years afterwards. He had a case under his care of a large growth of the pylorus, apparently malignant, where the patient would undoubtedly have died in a few hours, upon whom he performed gastro-jejunostomy and she lived for twelve years afterwards, when she died of another disease altogether. He had another case, one of carcinoma of the breast, so bad that it was given up as absolutely hopeless. At the express desire of the patient he removed the whole of her breast, pectoral muscles, and cleaned the axilla. That was sixteen years ago and she was alive and well to-day. He thought it most absurd to say that because a patient is *in extremis* one is not to give her a chance of life by operation. It has been stated that if an erosion bled freely on examination it was malignant, but that was not his experience. He understood the erosion in this case bled very freely, but yet was not malignant. As to the variety of incision which should be made in cases of cysto-carcinoma of the ovary, he thought it should be free, and that the cyst should be removed in its entirety. He had no experience in transverse abdominal incisions, as he always found longitudinal incisions to be sufficient.

Dr. JELLETT, replying to the President, said that in the case of advanced carcinoma of both ovaries, by the time the latter had been removed, the patient's pulse was 160, as she had been bleeding very profusely. There was consequently no time to examine the lumbar glands to ascertain whether they were affected. He did not make a transverse incision at first, because it was exploratory. The transverse incision which he subsequently made was about the only instance in which he had made that class of incision, and in this case it was necessary. He could not retract the abdominal walls sufficiently to get round the tumour, neither could he separate the latter in front or behind, so that he thought a transverse incision was the best to make with the object of getting outside the tumour. The incision healed well in spite of infection from the pus in the pelvis. He was glad there had been a unanimous opinion that the operation was advisable and justifiable. With regard to the case of double pyosalpinx, he granted there might have been a salpingitis previously to pregnancy but not a pyosalpinx. As to the question of bacillus coli infection from the rectum, there was no peritonitis subsequent to the operation. The pus at the time of the operation was apparently sterile as shown by the fact that the patient had no elevated temperature subsequently. The President had asked a question with regard to bleeding of the erosion. The section of the cervix which he removed was examined, and it consisted of an adenomatous growth. It bled because there was probably considerable uterine congestion, and though it suggested malignant disease, nevertheless it proved to be non-malignant.

Notes of cases were subsequently read by Mrs. Scharlieb, and a paper by Dr. Jellet, these with illustrations and discussion will appear in our next.

HARVEIAN SOCIETY OF LONDON.

CLINICAL MEETING HELD ON MARCH 8TH, 1906 (at the Hospital for Epilepsy and Paralysis, Maida Vale).

Dr. LEONARD GUTHRIE showed a case of Congenital Ataxy in a boy, *æt.* 5½. There was inco-ordination and intention tremor of the upper extremities, and the gait was unsteady. The knee-jerks were exaggerated.

Instruments had been used at birth. He attributed the condition to cerebellar meningeal hæmorrhage. He also showed two cases of Infantile Paralysis.

Dr. CAMPBELL THOMSON showed a case of Paralysis Agitans, with a peculiar gait which he termed intermittent claudication.

Dr. J. BROADBENT considered the condition to be functional.

Dr. GUTHRIE also held that the gait was functional. Mr. BARKER (for Dr. Ogilvie) showed a case of Tabes Dorsalis, in which great improvement in co-ordination had resulted from physical exercises.

Mr. MAYOU showed a case of Double Congenital Ptoxis in a child, and also a case of Paralysis Agitans in which rigidity without tremor was present.

Dr. BARKER (for Dr. Wilfred Harris) showed a case of Spasmodic Torticollis in a man, *æt.* 41, in which improvement had resulted from excision of a portion of the spinal accessory nerve, but the spasm was not completely arrested.

LARYNGOLOGICAL SOCIETY OF LONDON.

MEETING HELD FEBRUARY, 1906.

The President, Mr. CHARTERS SYMONDS in the Chair.

CASES were exhibited by the President, Drs. J. Donelan, Dundas Grant, Furniss Potter, Scanes Spicer, W. H. Kelson, and Stuart Low.

The PRESIDENT and Dr. DUNDAS GRANT exhibited cases of Frontal Sinus Suppuration, which had been treated by intranasal methods including dilatation of the infundibulum by means of bougies, and irrigation after removal of a part of the middle turbinal body. Skiagrams were exhibited showing the canula *in situ*.

The PRESIDENT considered that in a certain number of cases where there was pure frontal sinus disease it seemed possible to effect a practical cure.

The PRESIDENT also exhibited a case of Suppuration of the Left Frontal and the Left Maxillary Sinuses, in which irrigation alone had not effected a cure. The frontal sinus was opened externally, the lining membrane was entirely removed; the wound closed and the sinus treated by irrigation. The nasal suppuration was of eight years duration, and no recurrence had followed the operation. He considered the method superior to packing or the use of drainage tubes through the nose.

Dr. DUNDAS GRANT also exhibited a case illustrating the use of injections of cold paraffin for overcoming nasal deformity. The point in its favour was the immense convenience of being able to inject it without heating and without scalding the patient. It was urged on the contrary that the results would not be so permanent.

CORK MEDICAL AND SURGICAL SOCIETY.

MEETING HELD WEDNESDAY, FEB. 28TH, 1906.

The President, Dr. R. P. CROSBIE, in the Chair.

VESICAL CALCULUS IN A GIRL *ÆT.* 9.

Dr. COTTER read notes of this case. Patient did not complain of pain until December last, but the urine was "heavy" for some time previously. The pain was increased by jolting, and blood appeared in the urine, whilst vesical tenesmus and sudden stoppage of the flow occurred. Examination revealed a greatly enlarged clitoris, and per rectum, as well as by using the sound, he found that a large calculus was present. He decided to do suprapubic cystotomy, and in order to raise the bladder as high as possible, put the patient in the Trendelenburg position, which proved more convenient than the rubber bag in the rectum. He had no difficulty in removing the stone, which was as big as a Brazil nut, and, as its section showed, composed of phosphates laid down on a nucleus of uric

acid. The bladder was drained with a rubber tube, and the wound closed in eighteen days.

Dr. CUMMINS, Dr. O'BRIEN, and the CHAIRMAN spoke approvingly of the adoption of the Trendelenburg position in this operation. Dr. O'Brien thought that the use of a rubber catheter, passed into the bladder through the operation, would have ensured more satisfactory drainage, and cited a case of his own in support.

REPEATED EXCISION OF THE KNEE-JOINT.

Dr. CUMMINS showed a girl, *æt.* 16, on whose left knee he had done, four years ago, an excision. He used Allingham's method—*i.e.*, longitudinal section of the patella, and removed all the affected tissues. The patient made a good recovery, and he showed her to the Society at that time. Unfortunately, some time after this she injured the joint in a fall, and presented herself again with the knee flexed at right angles; he again operated, this time adopting the transverse U-shaped incision, with transverse section of the patella, and removing a wedge-shaped piece of bone. The result was that the patient had an excellent limb, which was only 1½ inches short.

Dr. COTTER preferred the U-shaped incision, as it gave better access to the joint, and thought that it was of the utmost importance to fix the joint carefully after operation. He recommended House's splint for that purpose.

Dr. CUMMINS, replying, disagreed with Dr. Cotter about the incision. Having tried both, he found Allingham's method more satisfactory.

Dr. BARRY gave an account of "Secretin: its Preparation and Use in the Treatment of Diabetes Mellitus."

CASE OF ADDISON'S DISEASE.

Dr. CUMMINS showed suprarenal glands of a patient affected with this disease. The patient, a woman, showed the classical signs and symptoms, pigmentation and grave asthenia. There was no deposit of pigment in the buccal mucous membrane. *Post mortem* fibro-caseous disease of the suprarenal glands was discovered, with evidence of considerable inflammation around them, the right organ being adherent to the liver. Emphysema of both lungs existed, and a healed nodule, probably tuberculous, was found in the left lung. He commented on the extraordinary way in which the suprarenals at both sides had alone become affected, the small deposit in the lung excepted, and thought there must be some selective action at work in such cases.

PERFORATED GASTRIC ULCER, WITH RECOVERY UNDER MEDICAL TREATMENT.

Dr. BOOTH read notes of a young lady, with a history of indigestion, who had suddenly been seized with intense pain and collapse followed by vomiting. Examination revealed intense tenderness in the epigastric angle, the seat of the pain, board-like rigidity of the recto muscles, and disappearance of the liver dulness. The temperature was 97° and pulse 115, respiration rapid, shallow, and thoracic, whilst the patient had a very anxious expression of countenance. Recognising the gravity of the case, and suspecting a small perforation of a gastric ulcer, a second opinion was asked for, and Dr. Cummins came and confirmed the diagnosis. The friends refused to put her into hospital, and would not hear of an operation should such prove necessary. Accordingly, morphia was given hypodermically for forty-eight hours, saline enemata, which were well retained, given twice daily, and nothing at all given by the mouth for a week, patient being fed on nutrient enemata, given every four hours. At the end of a week hot water in small quantities was given by the mouth, subsequently albumin water and chicken broth, and finally peptonised milk. The temperature varied between 99·2° and 100·8° for the first week or ten days, the pain and tenderness gradually disappeared, and patient made a good, if tardy, recovery.

ULSTER MEDICAL SOCIETY.

LABORATORY MEETING IN THE ANATOMICAL DEPARTMENT, QUEEN'S COLLEGE, HELD ON THURSDAY, MARCH 15TH.

The President, Dr. Wm. CALWELL, in the Chair.

PROFESSOR SYMINGTON gave a demonstration of the "cerebral hemispheres in apes and man," illustrated by specimens and lantern slides. He traced the development of the brain from its simplest form in the marmoset upwards, paying special attention to the motor and visual areas. The very beautiful figures which he showed, which were all but one from specimens in his own possession, will, it is understood, be used in the forthcoming edition of "Quain's Anatomy."

Dr. W. J. WILSON gave a demonstration of "bacterial pleomorphism," illustrated by micro-photographs. The organisms dealt with were the *B. Coli*, Friedlander's pneumonia bacillus, and the plague bacillus, and the effects on each of these produced by urea in the culture medium was shown.

Dr. KIRKHOPE gave a demonstration of "infarcts of the placenta," illustrated by a series of micro-photographs.

Dr. CECIL SHAW gave a demonstration of the use of Zeiss's new projection microscope with micro-planar lens. Various microscopic sections of the eye were shown on the screen. The apparatus can be used in an ordinary class-room with lime-light, but if the electric arc light can be used it gives a much finer result.

Dr. LOWRY read a paper on "IRREGULAR CONTRACTIONS OF THE STOMACH AND THEIR RELATIONS TO HOUR-GLASS CONTRACTION." During the winter, Dr. Lowry has observed a number of cases in the anatomical rooms which at first sight seemed pathological, but were soon found to be too numerous to be so, in which the stomach had assumed a shape which in life would be considered pathological. These specimens were shown, and Professor Symington also showed a number of casts made by him from similar conditions observed by him.

A lively discussion on these specimens took place. Professors Symington, Lindsay, Symmers, Drs. Mitchell, McKisack, Fullerton, Dempsey and Calwell taking part. Several members considered these appearances due to rigor mortis, while others agreed with Dr. Lowry that they supported the theory of Canon, that the cardiac portion of the stomach acts as a reservoir only and the pyloric portion is the gastric mill where digestion proceeds.

Professor MILROY showed sections illustrating new methods of staining for the study of the central nervous system.

Professor SYMMERS showed a number of pathological preparations.

Professor SINCLAIR showed a series of tumours of the superior maxilla, and an osteo-sarcoma of the thigh.

Mr. A. B. MITCHELL showed (a) a cystic kidney mounted in glycerine; (b) a herniated appendix in a child; (c) an enchondroma of the scapula.

Mr. T. S. KIRK exhibited (a) a thyroid tumour; (b) a huge lipoma; (c) a carcinoma of the rectum; (d) a myxo-sarcoma.

Dr. J. SINGLETON DARLING exhibited (a) a malignant uterus removed by total hysterectomy; (b) a sarcoma involving the inferior maxilla.

Mr. ANDREW FULLERTON exhibited (a) a large kidney tumour; (b) a mixed carcinoma and sarcoma of the breast; (c) a carcinoma of the rectum.

Mr. R. J. JOHNSTON exhibited (a) three uteri removed by Wertheim's method; (b) a simple adenoma and a malignant adenoma; (c) several myomatous tumours.

Dr. BLAKELEY exhibited various microscopic sections.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS. ABROAD.

FRANCE.

Paris, March 17th, 1906.

TREATMENT OF EPILEPSY.

THE treatment of epilepsy consists, according to Prof. Rauzier of Montpellier, in first calming the hyper-excitability of the brain and secondly in avoiding everything that might provoke this hyper-excitability.

The first indication is met by the administration of bromides and particularly of bromide of potassium. The salt should be as pure as possible, that is to say without any mixture of chlorides, iodides, sulphate or carbonate of potash. Bromide of sodium was formerly recommended as a substitute to avoid the toxic action of potash salts; but it is inferior to them and the same may be said of the bromides of ammonium, strontium, lithium, gold, arsenic; bromide of camphor however, in doses of five grains three times a day, appears to possess an elective action on vertigo and loss of memory.

Ball and Charcot came to the conclusion, after repeated experiments, that the association of several bromides gave results superior to those furnished by an equivalent dose of one of them and recommended the use of poly-bromides, a mixture of bromide of potassium, sodium, and ammonium, the former predominating.

In what dose must the bromide be given? The answer depends on both the frequency of the attacks and the age of the patient. For the adult the average dose is one drachm or a drachm and a half a day, in aggravated cases the dose might be carried to two and three drachms. In one instance a daily dose of one ounce was given without causing any inconvenience.

By what sign can one know that the dose of the bromide in a given case is sufficient? Formerly anaesthesia of the pharynx was considered as the criterion, but that fact is not proved. Gilles de la Tourette demonstrated the value of another sign, that of the pupil. When the organism has been saturated with the bromide, the pupils dilate largely and are sluggish to the influence of light; where the dose is weak, on the contrary, the pupils either remain stationary or are but slightly dilated.

To avoid saturation and to prevent the patient from getting accustomed to the prescribed doses, it is the rule to administer the bromide by increasing and decreasing doses alternately.

For that purpose, the month is divided into two or three periods, each of them corresponding to the number of drachms prescribed, the larger doses coinciding with the period of the month in which the attacks generally come on.

The usual means of penetration for the solution of bromides is the mouth, the rectum is reserved for cases of gastric intolerance or during the attack. To mask the taste so disagreeable to some patients, Prof. Rauzier recommends the bromides to be taken in Vichy Water, milk, or beer.

How long should the treatment be continued? Voisin fixes the duration at ten years, but Gilles de la Tourette and M. Rauzier consider that that period should be considerably reduced, though a great deal depends on the intensity of the malady. In any case the treatment should be continued without interruption for a whole year. If the case is not a very severe one, the dose might be decreased progressively during the succeeding six months and finally suspended for a time. If on the other hand the form is grave, if the attacks follow closely on each other and resist the treatment, its duration should be considerably prolonged.

The results of the bromide treatment are generally favourable; with the first doses the number and

intensity of the attacks diminish; frequently they are suppressed for long periods and sometimes radical cures are effected. Unfortunately it is not always so; in a certain number of cases no result is obtained in spite of the most rigorous treatment.

The accidents termed bromism are well-known and with a view of minimising them Prof. Rauzier recommends (a) intestinal antiseptics; (b) arsenical preparations; (c) periodical purgatives; (d) diuretics, and particularly milk. One or two of these agents might be associated with the bromides as follows:

Bromide of potassium, 40 grm.;
Bromide of sodium, 20;
Bromide of ammonium, 10;
Benzoate of soda, 7;
Arsenical of soda, 0.08;
Water, 1 litre.

Three tablespoonfuls a day during the first week, four the second week, and five the third and fourth week.

To be continued without interruption for at least one year.

The second indication that of avoiding all excitability of the nervous system will be fulfilled by a lacto-vegetarian regime, frequent purging, and an absence of salt from the food. Besides, the patient will be enjoined to take physical and mental rest and to avoid any; over-exertion, excesses, or emotions.

GERMANY.

Berlin, March 17th, 1906.

At the Medical Society, Hr. O. Hauser discussed
OVERFEEDING OF INFANTS.

He said that although the feeding of infants had made great advances during the past few years in the better families, so that serious cases of diarrhoea with vomiting were becoming rare occurrences, yet in these same classes cases were frequently seen in which, without question, over-feeding had taken place. This was often begun during intra-uterine life, and huge children were born into the world, the birth of whom was hindered by their colossal size. That this intra-uterine fattening was not desirable, the experience of agriculturists with their cattle had shown.

It was still the end and aim of mothers to increase the weight of their children, and the only criterion of their thriving was the weighing scales. In the dilution of the milk in the first months of life, not enough attention was paid to the amount of fat contained in it; this was subject to the greatest variation in the different samples of such milk; later on foods were used, such as good butter, chocolate, sweets, artificial food preparations, and the like, all substances highly concentrated and containing no ballast. No wonder, therefore, that the digestion became upset and the children lost their appetites, even if these poor creatures had never learned the feeling of hunger. In infancy the child, up to this well nourished, suddenly became restless, began to take its food badly and to cry. Digestion ceased. With the idea that the food had been poor, it was made stronger, and the difficulty of getting it down became greater and greater until the usual growth-rate stood still. If food poor in fats was now given, the condition improved in a short time.

For the so-called exudative diathesis (urticaria strophulus, weeping rashes, &c.) the fatty constituent of the food was of importance. Experience also taught that fat-bodied children with rickets learned to run later than those normally nourished, and they got bow-legged.

General fattiness injured the heart, as we know in adults. Over-feeding threw more work on the bowels, for these did not develop; laxity followed, and finally function ceased; it was therefore a condition that might have the most severe consequences, and should be avoided. In the selection of food for infants, therefore, more attention should be paid than was

done to the calories of the food given, and to the individual constitution of the child.

Hr. Langstein remarked that an earlier work of Gzerny's was on this subject. Over-feeding was observed among children of poor people treated in the out-patient departments of hospitals, where food was given too often. In contrast to Breslau, where over-feeding was mostly from carbohydrates, it took place from milk in Berlin and was therefore accompanied with fat.

At the Laryngological Society, Hr. Grabower showed a youth, æt. 17, suffering from

PARALYSIS OF THE RIGHT RECURRENT NERVE FROM EXTIRPATION OF THE THYROID.

Immediately after the operation the voice was good, but the breath was short. Four days later this shortness of breath disappeared, but hoarseness took its place. On the seventh day the right vocal cord took the position of that of the cadaver; the left, on phonation, reached to the middle line. It was not until two or three weeks after that it passed the middle line, and it now lay alongside the paralysed cord. As in experiments on animals, it must be assumed that the cord was held tense by the crico-thyroid, and that it only assumed the cadaveric position on paralysis of this.

The speaker observed that it was usually the right recurrent nerve that was severed in thyroid operations, and that this occurred through the text-books giving incorrect information that the recurrent on its return passed between the trachea and the œsophagus. This was so as regarded the left nerve, but the right passes into the groove only at the level of the ninth or tenth tracheal ring.

THE SERUM TREATMENT OF SCARLATINA.

The *Deutsche Med. Zeitung*, No. 11, contains a reference on this subject to a paper by Dr. C. Zuppinger. He recommends the use of Moser's scarlatina serum in severe cases of the disease, and reports on thirty-eight cases treated by it during two and a half years. Ten of these were severe cases, of which six recovered and four died; there were further five cases in which the prognosis was almost fatal four of which recovered, and lastly, three cases with an absolutely fatal prognosis, all of which recovered.

It was of the utmost possible importance to inject early, and best during the first three days of the disease, and before general sepsis supervened. The treatment proved most effective in those cases in which the throat symptoms were the most pronounced; its action was less marked on the local processes in the nose and throat, although it did exert influence on these localities.

In most cases a critical fall of temperature took place (1° to 3° C.), with a succeeding sub or afebrile stage, the general condition improved, the pulse and respiration frequency fell.

The autopsies on the fatal cases showed, as regarded the first, purulent peritonitis, pneumonia, pleurisy, nephritis; death seventeen days after the injection. Second, scarlatina intoxication with hæmorrhagic nephritis and purulent cellular infiltration of the injection site on the left thigh. Three and four died of extensive inflammation of the lungs on the eighteenth and thirtieth day respectively.

Five after sixteen days of septicæmia and pericarditis, purulent and hæmorrhagic nephritis.

Nephritis took place in six of the twenty-eight cases; in fifteen a serum exanthem between the fourth and sixteenth day an urticaria-like rash, partly with and partly without fever. As regarded the quantity of serum injected, it was 100 to 300 ccm. in the severe cases. Several times along with diphtheritic serum when there was diphtheria as well. The writer claims that when injected in full dose and at the right time Moser's serum has a powerful specific action on the scarlatina poison, and that in severe cases "it alone has saved life up to the present."

AUSTRIA.

Vienna, March 17th, 1906.

GRIPPE-ENDEMIC.

JEHLE brought the subject of epidemic Grippe before the "Gesellschaft" for internal medicine, which he had investigated at the St. Ann Hospital. This investigation arose in consequence of a repetition of similar cases coming into the institution during the months of October and November last year, and running the same course with similar symptoms, viz. high fever, sneezing and running at the nose without any other clinical symptoms or sequelæ except the rapid fall off in weight. In October the first was admitted as a simple fever which continued ten days and then subsided. Before the defervescence occurred other three were admitted, rapidly succeeded by others in greater number. In November a pause intervened, but the beginning of January brought five new cases, succeeded by another rush of new cases. This occurred three times with the same results. The children in the hospital were isolated and thus escaped the infection which evidently persisted at these periods. The nasal secretion and the presence of the micrococcus catarrhalis regularly present in the discharge confirmed the diagnosis. Cultures of the micrococcus produced the same result.

All treatment at first took little or no effect. On the 13th January, everyone of the little sufferers had 10 minims of Pyocyanase run into the nasal cavity with a douche. Forty-eight hours later not a single micrococcus catarrhalis could be found in the secretion and the children rapidly recovered.

TUBERCLE IN THE NASAL MUCOUS MEMBRANE.

Panzer showed a boy, æt. 13, who came to him complaining of stoppage in his nose which had troubled him since the summer holidays. The organ had a swollen appearance externally as if œdematose, but more accentuated about the point or alae. The bones of the nose were entire and normal in appearance, but the mucous membrane over the cartilage of the septum near the point on the right side was ulcerated exuding a yellow discharge with which it was covered. Around the margin of this ulcer were fine nodules, but the other parts of the mucous membrane were normal. At the angle of the lower jaw the glands were swollen to the size of hazel nuts and tender. Is it a gummosus ulcer? was the first question. The ulceration and yellow nodules in the margin, the site being confined to the point of the nose, while the bones are free and normal, and existing for months without any change were against gumma.

From its local attack the conclusion was tubercle, and that it had been infected by the patient rubbing and scratching the mucous membrane with unclean fingers and infecting himself.

The treatment might be surgical, but he thought this case might undergo Escherich's injections with tuberculin, which he purposed trying.

EMBOLISM IN POST-DIPHTHERIA.

Escherich at this point produced several preparations which he had taken from patients, where injections had been administered for diphtheria, and death resulting in cardiac paralysis which happily was not a common accident.

The first was a female child, æt. 13 months, who died on the sixteenth day. Apart from the morbid changes met with in the pharynx and bronchi, there was a fatty degeneration of the cardiac muscle; the left ventricle distended, and in the apex of the organ was a round mulberry clot, fixed in the trabeculæ, which when cut, had a greyish appearance, while fresh infarcts were found in both kidneys.

Case 2 had œdema of the cellular tissue, peritoneal dropsy; heart enlarged, soft, and valves intact. In the apex of left ventricle a clot about the size and consistence found in the preceding case. In the right ventricle were a few small clots entangled in the trabeculæ in a similar manner.

In all the branches of the pulmonary artery were emboli, while fresh infarcts were found in the kidneys.

The third case had dilatation and fatty degeneration of the cardiac muscle, thrombi in the right auricle, and fresh infarct in kidneys, but besides this there was chronic tuberculosis in the tracheo-bronchial lymphatics.

The fourth case developed cardiac weakness on the eleventh day; on the sixteenth paralysis of uvula; from the 29th to the 36th day, hæmaturia, which soon passed off, leaving the patient much improved and finally without albumen in urine.

In all these cases the thrombi and emboli are the result of post-diphtheritic enfeeblement of the heart, which would reduce the circulation and allow the coagula to form in the vessels. Whether the changes in the cardiac muscle is the cause of the formation of the clot, or the clot the cause of the enfeeblement of the heart is not easy to determine. The most practical point to be borne in mind is the danger attending a post-diphtheritic heart weakened by the poison and liable to give way at any moment. Everything should therefore be done to avoid the impediment of the heart, in our treatment of diphtheria.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

ADMINISTRATIVE CONTROL OF PHTHISIS.

THE Local Government Board issued on March 10th an important circular bearing on the administrative machinery and organisation of special measures for the control of phthisis. The circular is too long to quote in full in this column, and only a short synopsis will be given.

I.—The first section emphasises the infective nature of consumption, and shows that consumptive advanced in the disease are sources of danger to healthy persons. The concluding paragraph runs: "Accordingly, the sections of the Public Health Act applicable to other infectious diseases are equally applicable to pulmonary phthisis, and the obligation resting on the Local Authority to deal with and control infectious disease extends to pulmonary phthisis.

II. DISINFECTION.—All the provisions of the statute with regard to disinfection are available for dealing with phthisis, and should be enforced if necessary. Disinfection should not be left to friends, but should be carried out by experts, especially in the case of rooms which have been occupied by consumption for long periods. Places of public resort—schools, churches, halls, markets, stations, &c., and public conveyances ought to be disinfected periodically. The ordinary precautions should be taken with regard to sputum. The provision of the Act prohibiting the exposure of infected material, and prohibiting infected persons from exposing themselves without taking proper precautions against spreading the disease, should be enforced in the case of tuberculosis. Local authorities should also exercise the powers conveyed by the Act and see that no person living in an infected house shall milk any animal, pick fruit, engage in any occupation connected with food, or carry on any trade likely to spread the disease.

III. ISOLATION AND TREATMENT.—The provisions of the Public Health Act as to hospital treatment for other infectious diseases are equally applicable to phthisis. Hospitals for pulmonary phthisis may be classified as follows:—

(a) *Curative Hospitals for Early Cases (Sanatoria).*—The point insisted on in reference to these is that to obtain good results highly specialised medical supervision is essential, and that therefore local authorities, instead of trying by themselves to provide the trained medical skill and scientific laboratories necessary, should either utilise existing sanatoria or combine with other authorities to erect a thoroughly well-equipped one. The local authority (or its Phthisis

Committee") should aim at keeping in touch with all available sanatoria, either in the locality or at a distance. The circular adds that "sanatoria may be of the simplest and cheapest form."

(b) *All-day Hospitals.*—Where the patient's home is suitable he may attend the sanatorium all day for treatment and return home at night. Thus the resources of the hospital are made more widely available without increased ward accommodation being needed. Extra shelters alone are necessary.

(c) *All-night Hospitals.*—For some patients, whose occupation is out of doors and in every way compatible with the treatment of the disease, but whose homes are unsuitable, arrangements can be made whereby they work during the day and sleep in the sanatorium at night.

(d) *Convalescent Homes, Colonies.*—Work colonies or homes are desirable to complete the cure begun in the sanatorium. If well organised these might be almost self-supporting. Patients would be specially selected and provided with light labour.

(e) *Hospital Wards for Educative Treatment and Control.*—In several towns vacant wards of ordinary fever hospitals have been used for the educative treatment of phthisical patients. The case of Brighton is instanced particularly; there the patients are admitted to full sanatorium treatment for one month and are taught the value of fresh air, &c., and the best means of preventing spread of infection. Meanwhile, their homes are disinfected, and on their return they are visited periodically by the local authorities.

(f) *Hospital Wards for Isolating Advanced Cases.*—Vacant wards of a fever hospital should be utilised. The isolation of such dangerous cases is a primary duty of the local authority.

(g) *Dispensaries for Pulmonary Phthisis.*—The work of these includes (1) medical examination of the patients; (2) inquiry into the economic and social aspects of the cases with reference to the best means of treatment (home or hospital); (3) medical treatment and nursing of patients at home, in suitable cases; (4) dispensing medicine and disinfectants; (5) arranging for periodic disinfection of clothes, &c.; (6) selection of cases for any of the enumerated forms of hospital treatment; this is one of the most important parts of dispensary work; (7) distribution of printed information relative to phthisis; (8) examination of sputum, blood, &c.; (9) arranging for removal of cases to hospital; (10) general medical supervision and control of cases of phthisis not removed to hospital. The district or municipal phthisis dispensary should be a central bureau of information. It should keep a register of sanatoria, hospitals, and other institutions and organisations which can be made available for the inhabitants of the locality.

IV.—NOTIFICATION OF PHTHISIS.—The Board are prepared to sanction the addition by any local authority of phthisis to the list of notifiable diseases, provided the local authority are prepared, and able, to deal effectively with the cases notified. Notification alone is of no administrative value.

V. ORGANISATION.—It has been shown that the Public Health Act applies to phthisis, and the agencies which can be employed in controlling the disease have been indicated. But so highly specialised an organisation demands the services of a sub-committee of the Public Health Committee. This sub-committee—the Phthisis Committee—should have charge of the dispensary, which should be the administrative centre of the whole organisation. The dispensary will normally be under the direct management of the Medical Officer of Health, and will constitute a special department of his work.

VI. CONCLUSION.—The concluding paragraph of the circular reminds local authorities that these direct measures of prevention and cure must be supplemented by indirect measures in the shape of unremitting attention to general sanitation. Altogether, the Circular is a most ably drawn document, and covers the whole field of the administrative treatment of tuberculosis in a

most exhaustive and systematic fashion. To read it, and recollect the state of public and professional opinion as regards phthisis fifteen or even ten years ago, is to become conscious that we have covered much ground since then. Who knows what another ten or fifteen years may see?

EDINBURGH UNIVERSITY STUDENTS AND THE PRINCIPAL.

At a meeting of the Representative Council on March 9th it was unanimously agreed to issue an appeal to the students to mark in some tangible way the respect and appreciation in which they held Sir William Turner, who has now completed fifty years of active official academic service in the University of Edinburgh. Mr. J. Ian Macpherson, in seconding the resolution, said that Sir William Turner took a deep and sincere interest in everything that concerned the welfare of the students. The resolution was carried by acclamation, and a committee appointed to carry it into effect.

BELFAST.

FEVER AND FURNITURE.—A case of considerable interest was heard in the Summons Court last week, when the Belfast Corporation brought a suit against certain furniture dealers, whose names suggested that they were aliens, for having removed a quantity of furniture from a house where there was infectious disease, namely, typhoid fever. The furniture had been obtained on the hire system, and was removed during the illness of a child in the house, though the furniture dealers were informed of the illness. A fine of £3 and costs was imposed.

PUBLIC HEALTH.—The executive sanitary officer is showing a commendable vigilance in the matter of the sale of unwholesome shell-fish in Belfast. There is no doubt that typhoid has been caused by the consumption of shell-fish gathered on the shores of Belfast Lough, where they flourish in the dilute sewage of the city. Arrangements have been made for the bacteriological examination of specimens from different parts of the lough, so that rules may be laid down as to the localities from which they may or may not be gathered for sale.

LETTERS TO THE EDITOR.

THE OPSONIC INDEX.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent "Criticus," has not gathered the gist of my letter of March 7th, if he thinks I condemn Wright's Opsonic Index simply because it is technical. My contention is very different, merely that in its present form it is too complicated, technical and expensive to be used widely either in hospitals or in private practice. "Criticus" tackles me about the cost, which he says in some place he does not mention he places at a guinea and a half, instead of ten guineas, the usual charge in a London laboratory. Does "Criticus" think seriously that tests on hospital and other patients are likely to be used extensively at thirty-one shillings and sixpence apiece, when the general practitioner has often to whistle for his half-crown? If Professor Wright's ingenious index stands the test of time it will have to emerge in a cheap, simple, speedy and practical form. This is the deliberate verdict of not a few well-informed men who have investigated the matter impartially in London. "Criticus" evidently looks at the thing through the rose-coloured glasses of a young enthusiasm. Nothing else could have prompted his remarks that the end of my letter dismisses the subject with "sneers and gibes." With some curiosity I referred to that letter, and mention that the opsonic index of normal blood varies between 0.5 and 1.3, and I call that "a fine standard for a system that aspires to finality in accurate estimation." This may be a sneer, but what I wrote in haste I repeat at leisure, and state my deliberate opinion that it is not only "fine," but in less able hands than those of Professor Wright it would have been final at the outset. The system

is beset with fallacies, as "Criticus" will one day discover if his ardent researches extend over a sufficiently long period.

I am, sir, yours truly,

CUNCTATOR.

Balham, London, S.W.

VACCINATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Bitter complaints have been made to me by practitioners in Dublin who are not on the Poor-law Service on account of the issue of notices for vaccination, such as the enclosed, to their patients. They have stated that the notice contains an illegal threat to their private patients, who, instead of being told that they must have their child vaccinated (by their own doctor, or by any doctor), are unlawfully terrorised into the belief that the child must be brought to the dispensary, and the operation performed there under pain of prosecution. They allege that a triple injustice is done—to the private practitioner, who is deprived of that fee which the patient is willing to pay; to the ratepayer, who is saddled with the charge which the parents of the child are ready to bear, and to the mother, who is alarmed by the threat into taking the child to the dispensary much against her will.

I have been asked to draw the attention of the Local Government Board to the matter, but I should like to have your opinion as to whether the notice, in its present form, is justifiable. So far as I can see from the Act it is not, and, of course, it is a serious thing to procure a fee under threats made by quoting an Act of Parliament which gives no such authority.

I am, sir, yours truly,

Dublin, March 15th.

L.R.C.S.I.

[The wording of the communication to which our correspondent takes exception is as follows:—

"COMPULSORY VACCINATION ACTS, IRELAND (26 & 27 Vict., cap. 52; and 42 & 43 Vic., cap. 70). Dispensary.—I have to acquaint you that if you do not bring or send your child to this dispensary on or before next Thursday morning, at 11 o'clock, for vaccination, your name will be returned as a defaulter for prosecution, after that date.—Signed, Medical Officer."

It would be interesting to know whether this notice is sent only to parents in whose case the legal period within which vaccination must be performed has been greatly exceeded, or whether it is sent as a preliminary notice in all cases. In either case its wording is perhaps not judicious, as it is obvious that if the parents produce a certificate of vaccination from their private medical adviser it will answer equally as well as the production of the child.—Ed.]

THE CENSUS OF THE EMPIRE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Publication of what you rightly style a great and historic blue-book—the census of the entire British Empire—ought to bring to the front discussion of some aspects of the population question which, by your favour, I have been allowed to examine from time to time in your valuable paper. How many Englishmen, even among the best-informed classes, are there to be found who have fully realised the fact that the total of the white population in these islands, our colonies, and India, does not exceed fifty-four millions, a number actually less than Germany possesses at home. Is it to be supposed that in the future such a handful of white men will be able to dominate the peoples you refer to—four hundred million human beings made up of every race, creed, language and cast. The white man's burden will become too great unless his number can be proportionately increased. There is room in our colonies for hundreds of millions, and unless we become prepared to avail ourselves of the limitless fertile lands now our property, they will in the end be overrun by more prolific or more virile races. If the yellow peril do not in time become a

reality it will be only because Germany and Russia, the two nations at present least affected by the most destructive vices of civilisation, shall have conquered and peopled the lands we may have shown ourselves incapable of properly utilising. Within a very few generations the French have gone far enough along the road towards race-suicide to show us what must be the end if we continue to follow their example. The French have, so to say, constructed a social system based upon the hypothesis that no more than two children, on an average, shall be produced by any married couple. This idea is too deep-rooted to be conquerable. The population for thirty years has remained stationary. France has lost for ever her predominant place in Europe, and as soon as Europe ceases to protect her against her virile neighbour, she will surely lose the vast oversea territories which, from the population point of view, are useless to her, whilst virtually essential to her hereditary enemy. At home and in our colonies we are rapidly adopting the French idea. The birth-rate at home during the last quarter of 1905 was the lowest on record. If this goes on it is possible, although by no means certain, that some amelioration in the lot of individuals saved from the care of numerous offspring may be effected, but the British Empire will be doomed to destruction. The Empire for its maintenance must have an exuberant population of an imperial type. The egoism which prevents the procreation of children through hatred of stress and toil, and through love of ease and pleasure will tend to develop a race not only few in numbers, but of a type devoid of the highest manly qualities. Such a race must in the end go down before any people with whom it is in permanent contact, and who, by accident or wise direction, have escaped the effects of those destructive agents which seem always to threaten the vitality of highly-civilised communities.

I am, sir, yours truly,
Mar. 19th, 1906. A STUDENT OF SOCIOLOGY.

REVIEWS OF BOOKS.

WORKS ON NURSING.

A STUDY IN NURSING. (a)

THIS suggestive little manual is not intended to be a technical guide to nursing, but is, as the authoress states, "the retrospect of an old worker which may be of use as a study to her juniors." As the review and admonition of a veteran, these pages will be welcomed by all those who recognise that nursing is not to be followed as a mere profession, but cultivated as a high art, in which sympathy as well as science must prevail. Text-books containing instruction in all nursing matters are numerous, but in the delightful little literary effort before us, we have the human, rather than the mechanical, side of work presented. Miss Pringle, with her unique experience and wide mental outlook, emphasises her convictions that a woman's qualifications for nursing do not lie solely, or even mainly in the direction of mere technical acquirements. These pages would seem to show that though in many respects we have travelled far during the last generation, yet the needs of nurses, and the means best calculated to produce the highest type, are as yet but imperfectly realised and seldom attained. There is no mistaking the high standard and intense seriousness of the work before us, and the holy example of service expected alike of those who direct and those who serve must prove in this utilitarian age an incentive and inspiration. We venture to think that no member of the profession will lay down this little book without feeling that, though "the ministering angel must have her wings tied under her apron," she is called to the dignity and duty of a divinely-appointed mission. Miss Pringle graphically

describes the evolution of nursing, indicates the nature of the many fields of service for nurses, discusses the organisation of a nursing staff, and enumerates the requirements and duties of the various members. Where so much is of the best, we are loth to find fault, but surely the authoress breaks through her own teaching of strict obedience to medical orders, when she suggests that the Sister, in receiving the new patient should, on her own responsibility arrange for him to be "surrounded with hot jars, and *fed with brandy and water*, or hot milk or beef tea." The italics are ours to mark our regret at the perpetuation of an antiquated and unscientific procedure. Miss Pringle advocates the use of nuns as nurses in Irish workhouse infirmaries. We commend this instructive and invigorating little manual, with its motto "Amare et servire," to all matrons, nurses, and those interested in the elevation of nursing in this country.

MCGREGOR'S SURGICAL NURSING. (a)

THIS is more than a mere text-book of nursing. In fact, it is a manual of surgical affections, for the diseases of the various systems are carefully described in a manner well suited to the requirements of nurses. There are also chapters on such subjects as bacteria, antiseptics and anæsthetics. Full details are given of routine work such as bandaging, feeding, massage, and electrical treatment. The preparation of various kinds of dressings, instruments and sutures is minutely described, nothing of importance to the nurse being omitted in their consideration. When we say that the book contains forty-two chapters, and possesses a double-column index extending to fifteen pages, some idea may be formed as to its scope and completeness. In some respects, indeed, the volume appears to us to be somewhat too encyclopædic in character. Nurses seldom care to read large books, and besides, they rarely have the necessary time or opportunity. At the same time we are bound to admit that the writer's teaching is sound, and his book easily read. The last chapter, dealing as it does with the arrangement of nurses' duties, may be read with profit by every hospital nurse, for it contains a vast amount of very helpful and, at the same time, suggestive information. In another edition more space might be devoted to massage, especially as this is now being largely employed in cases of fracture. Otherwise we consider that the writer has been judicious in his allocation of space to the various subjects brought under review. This will long remain a standard work on surgical nursing, as its teaching is authoritative.

DRUMMOND'S SICK NURSING. (b)

THIS is essentially an apron-pocket book, and one which, as the writer himself says, is "quite elementary." It contains a number of useful facts, but some of the directions given are somewhat peculiar. Thus, on page 34, in speaking of how to pour out a medicine, the author instructs the nurse to withdraw the cork "with the little finger of the left hand," not a very easily acquired mode of procedure, we should imagine. Again (p. 17) for cleaning paint, he recommends the use of "warm soap and water." Evidently what the writer means is warm water and soap, but he does not unfortunately say so. Regarding the annoyance caused by too much sunlight in a ward he says: "This may sometimes be remedied by moving the patient's bed slightly." This surely is not to be recommended in hospital nursing. Nurses affected with soreness of the feet are advised to bathe them in cold water several times a day, but we would remind the author that this is not by any means easily carried out by hospital

nurses. The direction given on page 55 to "apply liniments by rubbing them gently with the skin" evidently needs correction. The list of words and phrases given as occurring "frequently" in prescriptions contains one or two which are seldom employed, and therefore would have been better omitted. This little monitor will, however, be found useful by probationers during their period of training; but we can hardly hope as the author does, that even "some at least of the sections may be of service to nurses of greater experience." We doubt very much if even the most experienced medical man is able to write a book of this kind without feeling that he is traversing somewhat untried ground.

VOYSEY'S NURSING. (a)

THIS is a model of what a small handbook on nursing should be. It contains just the sort of information the probationer longs for. Bristling with hints and warnings, this book is sure to prove of great service to the junior nurse, who is often in need of advice. Thus it tells how to make a bed, take a pulse, give an enema, as well as how to use the hypodermic syringe, and to fix up the aspirator. In every case the directions given are short, simple and very explicit. A few pardonable errors, however, have crept into the text such as "inter-uterine," douches (p. 66), but on the whole the book is free from important mistakes. In fact, it is with feelings of pleasure that we have read it, and were also favourably impressed with the boldness of the type, and the well-planned arrangement of the subject matter. We know of no better guide to nursing for beginners than this, and feel certain that it will be appreciated by the probationer who is often at a loss as to what to do when an order has been given her. With this little book at hand she will be able to carry out her instructions with intelligence and even with credit to herself.

DISEASES OF CHILDREN. (b)

IT is with sincere pleasure that we welcome the fifth edition of Dr. Ashby's and Mr. Wright's Diseases of Children, for in the sixteen years that have elapsed since the book first appeared it has established for itself a commanding position in the domain of Pæchatties. And it has done so in virtue of its intrinsic worth. If we were asked in what this worth principally consisted, we should say in its evident sincerity, its fidelity to the clinical observations of two painstaking and thoughtful minds. The authors have founded their work on their own experience at the Manchester Children's Hospital, and in private practice, and the book throughout is redolent of the bedside. It is palpably not a made-up book, brought out to meet a demand, but one that is the outcome of much travail and patient labour. Its fault—if fault it be—is that 900 pages are too few for the adequate presentation of all the medical and surgical diseases to which children are liable, and consequently some of the topics have to be treated hurriedly. This is especially noticeable in the chapters on special subjects, such as the ear and the skin; whilst the eye is not dealt with except incidentally. On the other hand we especially commend the excellent chapters on the diseases of the digestive and nervous systems, by Dr. Ashby, and those on diseases of the bones and joints by Mr. Wright. The authors are evidently thoroughly at home when treating of these subjects, and their descriptions are lucid, informing, and thoroughly sound. It is perhaps unreasonable to expect all the sections to be of the same amplitude as those mentioned, for if they were the book would have to be considerably enlarged, and the authors have

certainly assigned more space to the most important matters. But one cannot help feeling that the book would be well nigh perfect if all the maladies of children were dealt with in the same masterly fashion. Certain points suggest themselves for criticism, such as the use of the word "stoved" on page 293, as a synonym for "disinfected," but they are so few and the work has been so thoroughly revised from time to time that there is no room for serious objection. Besides criticism is disarmed by the authors' method, which is to assert facts observed by themselves—and the conclusions that these facts suggested to their minds; generalisations in the main are avoided, and besides silencing criticism their comparative infrequency invests the writing with a personal air of considerable charm. Besides the text proper, certain useful features will be found—a chapter on "Anæsthetics for Children," by Mr. Alexander Wilson, which is the best thing on the subject we have read for some time; an appendix on nvalid foods for children; and ten pages of capital formulæ for prescriptions. We can say emphatically that no practitioner in any sphere of medicine could invest a guinea to better purpose than in the purchase of this able and fascinating book.

Poisonous Drugs Prescribed by a Herbalist.

AT Cefn yesterday week, Dr. W. R. Jones resumed the inquest on the body of Margaret Thomas, a married woman, of Lower Vaynor Road, who died recently after a miscarriage. At the original inquiry, it was alleged that the woman had purchased medicine containing deleterious drugs from a herbalist named Arthur Roberts, and that there were several packets of herbs found about the house after her death, there being no proof, however, that of these Roberts was the seller.

Dr. Flood said he attributed death to gastric ulcer in the stomach causing peritonitis.

The Coroner: Can you give us any idea how these symptoms were brought about?

Witness: I think they may have been assisted by the irritating medicines which the deceased had periodically taken.

The Coroner said there was a weak solution of a herb in one of the samples. Was that herb used for criminal purposes?—Witness: Yes.

The Coroner said the man Roberts alleged that he sold the medicine for bronchitis, but that was all nonsense.

Roberts was re-called, and he was asked what he meant when he described himself as a herbalist.—"A man that practices by herbs," was the reply. You prescribe chloroform?—Yes.

What herb is that?—Chloroform is a mixture made or sold by the chemist, not by me.

But you prescribe it, don't you?—I prescribe it in the prescription when I write it down.

Answer me definitely. Do you prescribe chloroform?—Yes, in my mixture for bronchitis.

The Coroner in addressing the jury, said that Dr. Flood did the proper thing when he refused to give a certificate of death. These certificates were given by medical men too readily. The doctor showed moral courage, and did his duty to his profession. He thought this inquiry had been productive of some good in exposing a man of the character of Arthur Roberts. The drugs were constantly advertised in the papers as calculated to produce miscarriage, and it was a great shame that such advertisements should be allowed to appear. Roberts had escaped the clutches of the law, but he, nevertheless, thought it would have been well if he had been brought within its claws. Roberts was unable to spell ordinary simple words, and was ignorant in every shape and form, and yet he practised with drugs to deal with which required the experience of a lifetime. He hoped that what had transpired at the inquest would be a lesson to all the people of Cefn not to admit such men inside their doors.

The jury returned a verdict in accordance with the medical testimony, and asked the coroner to administer to Roberts a severe censure.

MEDICAL NEWS IN BRIEF.

The Graduates Association of the Royal University of Ireland.

THE Council of the Royal University Graduates' Association issued last week a series of resolutions which have been unanimously adopted at a meeting held in Belfast. These may be summarised as follows:

(1) We have observed with profound distrust the resolution proposed by the Most Rev. Dr. O'Dwyer, and carried at the meeting of the Royal University Senate on the 7th inst.

(2) Having regard to the facts, we are forced to the conclusion that this latest move of the majority of the Senate is an insidious attempt to have the University re-constructed on denominational lines.

(3) We consider that henceforward full and complete reports shall be issued of all business conducted at the Senate, save the ordinary work of routine administration.

(4) We affirm our determined opposition to any settlement of the University question involving the expenditure of State money upon ecclesiastical or sectarian institutions, and in particular we deprecate the scheme suggested by Sir West Ridgeway.

(5) We demand that any grant in aid of University education in Ireland shall be allocated only after full discussion in Parliament, and we call upon his Majesty's Ministers when dealing with the educational affairs of Ireland to give effect to the principle so emphatically declared by them during the recent election, viz.—that State education must be freed entirely from ecclesiastical and sectarian control.

Central Criminal Court.

CHARLES FOXLEE (on bail) pleaded guilty to publishing a false and defamatory libel concerning Dr. Arthur Robert Waddell, of Potter's Bar. Mr. Leycester said the libel was in a circular in which the defendant accused the prosecutor with being intoxicated and neglecting his duties when attending his wife in January, 1898. He also said the doctor had performed a cruel and unnecessary operation upon his infant child, and had permanently injured the child. As a fact, the doctor was and had been a total abstainer, and on the night of the wife's illness he had been attending two ladies, who would have been witnesses on his behalf had it been necessary. Before the publication of the libel the accused had subjected the doctor to all kinds of annoyance, with the object apparently of compelling him to pay some sort of compensation for what he said was his neglect. On two occasions the doctor had been compelled to eject him from his house. Foxlee had threatened the doctor with personal violence and in an anonymous letter he sent to the doctor the latter was advised to settle the matter with the view of preventing the scandal being made public. These letters culminated in the publication of the libellous circular.

Mr. Percival Hughes said the accused desired to express his deepest regret for his publication of the libel, for which there was no justification whatever. No doubt the accused was misled by the statements of his wife and the nurse, and for a long time he intended to take civil proceedings against the doctor upon those statements, which he then believed. It was while brooding over this fancied grievance, for which he had since found there was no ground whatever, that his mind became temporarily unhinged, and he did that which he now much regretted.

The Recorder said after the defendant's expression of regret and under his promise not to repeat the libel he would accept two sureties in £50 each for his appearance to come up for sentence if called on. The defendant was extremely fortunate in not having been tried upon the indictment charging him with threatening to publish the libel with the view of extorting money, for if he had been convicted of that

he would have been sent to prison. The defendant had admitted that the scandalous, false, and malicious libels were entirely without foundation. He earnestly hoped that these libels would not have any injurious effect upon the doctor professionally.

Irish Medical Schools' Graduates Association.

SOME three hundred ladies and gentlemen assembled at the Hotel Cecil on Saturday, March 17th, on the occasion of the annual festival dinner of the above Association. The presence of the fair sex lent a grateful relief to the rather ponderous appearance which is one of the characteristics of the Grand Hall, and the ladies themselves fully upheld the reputation for beauty generally associated with the daughters of Erin; it must be confessed, however, that even this failed to stimulate the after-dinner oratory to the heights of geniality and wit which the Saxon always expects from the Celt. After the President Dr. E. Terrin Scott, had given the usual loyal toasts, Dr. George Stokes, C.M.G., proposed "Our Defenders" this being responded to by Inspector-General W. H. Lloyd, and by Lieut.-General Sir John French. The next toast, "Our Guests," was entrusted to Sir William Whitla, but this distinguished physician having been called away, Dr. Macnaughton-Jones stepped boldly into the breach and made some very flattering but none the less true remarks about Sir John French, who in his response gave the best speech of the evening, referring in laudatory terms to the medical officers of the army, and paying a graceful tribute to the civil surgeons who went out to the South African war, notably to the late Sir W. MacCormac. Messrs. Mayo Robson and Arbuthnot Lane also responded to the toast, the former drawing particular attention to the fact of the fellowship of the R.C.S. (I.) not being a sufficient qualification for the appointment of surgeon to a London hospital. The last toast, "Ourselves," was proposed by Mr. R. G. Webster, who infused a little more humour into his speech than the former speakers, but here again there was the same absence of a "trifle of the brogue" which we had been longing for all the evening. Some charming Irish songs were efficiently rendered by the Hon. Mrs. Julian Clifford, and Mr. A. Bovett; Mr. Arthur Prince gave his ventriloquial entertainment, and Mr. G. H. Snazelle was funny in his "humorous tales," although one of them was the well-worn "Bill Adams."

The Forthcoming International Congress of Medicine at Lisbon.

A MEETING of the National Committee for Great Britain and Ireland of the Fifteenth International Congress was held at the Medical Society's rooms on March 13th. Dr. Pavy, F.R.S., President was in the chair. The honorary secretaries (Dr. Clive Riviere and Mr. D'Arcy Power) reported that the railway companies had made important concessions to members attending the Congress. The British Association at Oporto invited twenty members of the Congress to dine in the Factory House on April 25th, and they also extended hospitality to the other members. The following communication was read from the German National Committee:—"The German National Committee beg to submit the following proposition:—

"That an International Bureau be established which should continue in activity in the intervals between the meetings, with the headquarters in Paris. Its business should be to maintain the continuity of the Congress, and to co-operate with the organising committee in the arrangement of the programme as far as concerns the division into sections, and the choice of themes, of reporters, honorary presidents, &c.

"2. That in future the International Medical Congress should be held, not as hitherto, every three, but every five years"

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specialty compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT LITERATURE OF PHYSIOLOGY AND PATHOLOGY.

Primary Cancer of the Bronchi.—Nanu-Muscal (*Spitalul*, 1905, No. 7) points out that primary cancer of the bronchi is a rare affection, inasmuch as only thirty-six cases have been recorded. He himself reports a case which he had observed in a man, *æt.* 50, who had suffered from syphilis at the age of twenty years. Six months previous to his coming under observation the patient had been troubled with persistent hæmoptysis and with general weakness. On examination, the patient appeared cachectic, and a small tumour could be felt above the left sterno-clavicular articulation. Percussion dulness was present in both supraspinous fossae, especially the left, and also at the base of the left lung, while a slight tubular note could be made out on auscultation at the right apex. The sputum was yellowish and muco-purulent, and did not contain any tubercle bacilli. Weakness rapidly increased and the case came to autopsy. A large carcinomatous mass was found taking origin from the termination of the left bronchus and extending into the lung, while a similar growth was found involving the lower end of the trachea. M.

Sudden Death in Acute Rheumatic Fever.—Gouget (*Presse Méd.*, 1905, No. 39) distinguishes three clinical varieties of sudden death occurring in acute rheumatism, as follows:—(1) Cerebral congestion, which without warning, suddenly appears at the commencement of the attack, is accompanied by delirium, and leads to death in a few hours. Anatomically one finds in these cases only slight hyperæmia of the meninges, while clinically a history of alcoholism is usually obtained; (2) sudden death from syncope, without previous appearance of heart weakness or heart disease having been present. P. m., dilatation of all the cardiac chambers and diffuse myocarditis are usually met with; (3) death from asphyxia, including cases of acute pulmonary œdema, cases of embolism of the pulmonary arteries, and cases of intracardiac thrombosis. The author describes a case coming under the third heading, in which extensive intra-cardiac thrombosis had taken place, apparently caused by a staphylococcal infection. M.

The Cytorrhyses Luis.—Freund contributes a paper (*Wien. Klin. Woch.*, No. 38) on the subject of the protozoan parasite, which Siegel has described under the term Cytorrhyses Luis, and which the last-named author regards as the causal organism of syphilis. Freund found the protozoan in the blood of ten persons, of whom seven had syphilis without doubt, and three were suspected to be suffering from the disease. He has never found the parasite in the blood of healthy individuals. In some cases a marked effect on the flagellated organisms was noticed during the course of an inunction treatment. They were observed, in fact, to diminish in number and almost to disappear. Freund has also injected the blood of syphilitics into rabbits, and has separated the cytorrhyses from the blood of the infected animals after eight days, and has moreover observed large numbers of the organisms within the blood after the lapse of twenty days. No definite symptoms of sickness were, however, present in any of the animals experimented on. M.

The Blood of Epileptics.—Onuf and Lograsso (*Amer. Journ. Med. Sci.*, Feb., 1906, p. 269) have studied the blood of epileptics with the object of determining (1) The condition of the formed elements of the blood in the intervals between seizures; (2) the behaviour of the formed elements in connection with seizures. The conclusions at which they arrive are as follows:—(1) A leucocytosis may be present

before a seizure, but a seizure is not necessarily preceded or ushered in by a leucocytosis; (2) there is no absolute parallelism between seizure and leucocytosis, in so far as even when a distinct leucocytosis is present, such may reach its height at different periods in different seizures; (3) no notable change in the red cells takes place in connection with the fits. M.

Amputation of the Thigh with Re-plantation.—Carroll and Guthrie (*Amer. Journ. Med. Sci.*, Feb., 1906, p. 297) have performed experiments on dogs with the object of seeing if it were possible to immediately replant an entire limb after amputation. After some preliminary operations with a view to obtaining the necessary skill, amputation of the thigh was performed on an 8-kilometre dog. A few minutes after the amputation the severed limb was replaced in position, the femoral artery and vein were carefully united, and also the various nerves and muscles. Before the dressings were applied, it was noticed that pulsations in the popliteal and posterior tibial arteries could be felt. The next day the replanted limb was much warmer than the other, and there was considerable œdema. Nine hours later the limb was found to be quite cold, and a little dark blood escaped from an incision made in the foot. Fifty hours after operation the animal was chloroformed as gangrene seemed unavoidable. The subsequent examination showed the artery to be quite normal and seemed to point to the gangrene being caused by venous obstruction, the result of constriction by a celloidin dressing. The authors remark on the ease with which arterial circulation was restored and maintained, and believe that with more care replantation would be quite possible and successful. M.

Yellow Fever and Mosquitoes.—Marchaux and Simond of the French Mission to Rio de Janeiro, publish (*Annales de l'Institut Pasteur*, January 25th, 1906) a report on their researches into the causation of yellow fever, preceded by notes on recent advances by other observers. Of the latter two are of importance. (1) Otto and Neumann were able to bring alive to Hamburg from Brazil several specimens of *Stegomyia fasciata*. The race speedily died out when exposed to the open-air in that climate, though in a temperature of 27° it multiplied freely. It is easily killed by cold or by absence of moisture. These observations may abolish all fear of importing infectious insects to Northern Europe in ordinary baggage. (2) It has been shown that while virulent serum is rendered innocuous by passage through a Chamberland B. filter, if the serum be first mixed with an equal quantity of normal saline it retains its virus. Marchaux and Simond's own observations, which contain many new points may be summarised—(1) The virus of yellow fever may be transmitted from adult *stegomyia* to the egg; such infection probably plays but a slight part, if any, in the propagation of the disease; but it may cause the recrudescence of an outbreak all but extinct. (5) The virus of yellow fever may be artificially transmitted from mosquito to mosquito; but such transmission does not take place in nature. (3) The *stegomyia* does not become infected from the hæmorrhagic vomit or dejecta of yellow fever. (4) The larvæ of *st. f.* reared in water containing the fresh bodies of infected mosquitoes do not contract the infection. (5) An infected mosquito kept at a temperature of 20° appears to lose its infectivity. (6) Experiments on the possibility of transmission of infection by other mosquitoes than *Stegomyia fasciata* have given entirely negative results. (7) The female of *st. f.* does not, in this differing from many other

species, die after laying eggs, it is because of the power to lay several sets of eggs that she is able to serve as the intermediary host of yellow fever. It will be observed that search for the actual germ of yellow fever has as yet been entirely negative. R.

Vascular Theory of Epilepsy.—Turner (*Brit. Med. Journ.*, March 3rd, 1906) returns to the view of Hughlings Jackson, that the pathology of epilepsy is vascular, and consists in part of intra-vascular clotting in the cerebrum. Together with the vascular condition, however, there is necessary a defectively developed nervous system. Of the peculiarities which have been noticed in the nerve cells of epileptics, Turner emphasises two (a) the presence of a variety of nerve cells which represents an embryonic form, and is common in imbeciles; (b) the persistence in the brain of sub-cortical nerve cells. With regard to the effect of vascular changes he recalls certain experiments showing that clotting is a *vera cause* of convulsions. (1) Kussmaul and Turner showed that sudden ligation of the left subclavian and innominate arteries of a rabbit produced general convulsions in from three to forty-five seconds; compression of both carotids in six mice produced in two of them epileptiform seizures (2) Leonard Hill by sudden occlusion of one carotid was able to produce in certain cases a march of epileptic spasm preceded by an aura. (3) Introduction of oily substances to the vascular system produces in some cases epileptiform convulsions, the action of the oil being probably mechanical. In every case of epilepsy examined, (4) Turner found small cortical meningeal hæmorrhages, and these he believes to be due to rupture of small vessels consequent on clotting. While intra-vascular clotting is not peculiar to epileptics, Turner has met with it in 90 per cent, of epileptic brains, and in only 35 per cent, of control brains. Further, the maximum amount of clotting in the later series rarely, if ever, surpassed the minimum amount in the former. He regards the tendency to the formation of clots as associated with an increase in blood-platelets, which he has also observed in epileptics. R.

Placental Origin of Eclampsia.—Liepmann (*Münchener Med. Woch.*, Dec. 19th, 1905) makes an important communication on the toxicity of the placenta of eclamptic women. The placenta were minced, dried, and ground up, and a suspension in normal saline prepared, with the addition of a few drops of toluol. Injections were made in the peritoneal cavities of rabbits. The typical result was coma within a few minutes, accompanied by greatly accelerated breathing, widely dilated fixed pupils, and loss of reaction to sensory stimuli. In many cases convulsions ensued. Most of the animals, 113 in all, died within twelve hours. Experiments were then made bearing on the manner in which the toxin exists in the placenta. It was found that whereas the extracted placental juice was innocuous, injection of the placental pulp proved fatal. It was further found that the toxin is very labile and difficult to preserve, a powder which proved fatal one day being innocuous the next. When the relative toxicity of different placenta were studied, a curious result appeared. It was found that in cases where many fits had occurred the placenta was comparatively non-toxic, whereas in cases where only a few fits preceded delivery the placenta was highly toxic. From this it would follow that fits occur as a result of the passage of the toxin to the maternal circulation, and that they are a measure, not of the amount of toxin present, but of the amount which has thus passed over. As the most marked clinical phenomena depend on changes in the brain, Liepmann investigated the relation between brain substances and the toxic placental powder. He found that injection of a mixture of these substances gave rise to no disturbance. He therefore assumes that, as in the case of tetanotoxin, the toxin is fixed by brain cells. Liepmann's experiments will require careful verification. If his conclusions are supported, they constitute the most important

advance, both as regards theory and practice, made in recent years in the pathology of eclampsia. R.

NOTE.—A summary will appear each week in the following sequence:—

- (1) "Recent Medical Literature."
- (2) "Recent Surgical Literature."
- (3) "Recent Gynaecological and Obstetrical Literature."
- (4) "The Recent Literature of Physiology, and Pathology."

OBITUARY

GEORGE HENEAGE PEARCE, M.A.CANTAB.,
M.R.C.S., L.S.A.

WE regret to announce the death of Mr. G. H. Pearce, of the Borough Asylum, Leicester, as the result of an accident. While riding on a motor cycle with a friend on the 17th instant, near Rugby School, he came into collision with a cart. He was knocked off the machine, and the wheel of the cart passed over him. He died shortly afterwards while being conveyed to the Rugby Hospital. Deceased received his medical education at Cambridge and at St. Thomas' Hospital. He took the M.R.C.S. England in 1898.

THOMAS DUDDINGSTON WILSON, M.A., M.D.ED.,
F.R.C.S. ED.

THE death of Dr. Duddingston Wilson, at the age of fifty-five, occurred on March 8th, after a brief attack of pneumonia. Dr. Wilson was the eldest son of the late Dr. David Wilson, who for many years had a large practice in the City. He was educated at Edinburgh Academy, and studied medicine at Edinburgh University and in Paris. In 1875 he received his degree from Edinburgh University, and for a time thereafter he was resident physician in the Leith Hospital. Subsequently he held, for a few years, the post of medical superintendent at Craiglockhart Hydropathic. In 1883 he commenced on his own account, and soon acquired an extensive practice.

HENRY MATTHEWS TUCKWELL, M.D.,
F.R.C.P. OXON.

WE regret to announce the death of Dr. Henry M. Tuckwell, who had long retired from practice, last week in his seventy-second year at Oxford. Educated at Lincoln College, Oxford, and at St. Bartholomew's Hospital, London, he also studied on the continent. Dr. Tuckwell took the M.A. degree at Oxford in 1856, and was admitted a member of the Royal College of Surgeons, England, in 1858, and of the Royal College of Physicians, London, in 1862. He had been elected Radcliffe Travelling Fellow at Oxford, in 1859, and in 1863 took the M.D. degree. Seven years later he was elected a Fellow of the Royal College of Physicians, London.

MR. J. J. VEZEY.

THE death occurred suddenly on Tuesday of Mr. J. J. Vezey, F.R.M.S., chairman of the committee of the Miller Hospital, Greenwich. He was about to administer medical treatment to a patient at the institution, when he became unconscious, and died before aid could be summoned. Although the notices in the public press would suggest the contrary, Mr. Vezey was not a medical man, but interested in X-ray work, and held a lay appointment in the hospital. We believe the letters F.R.M.S. refer to the Microscopical Society.

NOTICES TO CORRESPONDENTS, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

M. O. H. (Ireland).—Special courses in meat and food inspection are arranged by the Royal Sanitary Institute, and examinations held in the same subject. If your authority is seriously contemplating the enforcement of a rigorous civic meat inspection it would be wise to send the special inspector to London for a course of instruction. Nothing in his department wants clearer and sounder knowledge.

MORPHIN.—The light treatment of lupus, so far from replacing ordinary methods, is neglected by many eminent and practical dermatologists. The same may be said of the X-ray treatment. Both methods are tedious and uncertain, while the X-ray is dangerous and the light-ray often followed by recurrence.

TRAINING ON EGGS.

A correspondent has drawn our attention to the fact that the Cambridge crew are training for the Boat Race on a staple diet of eggs. Five eggs a day is not a bad allowance for a man in training, that is to say, if he can take that number day after day without inconvenience or repugnance. There is, in our opinion, a vast deal of nonsense talked about diet in training. A full and varied dietary, without too much sweetstuff and rickshaws, and no alcohol, is about all that is required for the average Phillistine athlete. If he has to diet like a dyspeptic he had better keep away from the lists.

M.C.—If B was aware that C had been attending the case of suspected typhoid, and had given directions regarding its isolation, he should have advised the patient that a consultation with C was necessary before removing the embargo on his milk. If the patient refused to consent to this, then B should have reserved his diagnosis until all element of doubt had disappeared. It is, of course, possible that B was not informed that C had been in attendance, in which case B cannot be blamed for his action. C appears to us to have taken very commendable steps with the object of stamping out the fever.

CORK MEDICAL AND SURGICAL SOCIETY.—A CORRECTION.—It was erroneously stated in the notes of a case of nephrectomy for tuberculous kidney and ureter, published in our issue of Feb. 3rd in the transactions of the Cork Medical and Surgical Society, that clamp for ops were allowed to remain on the renal vessels for forty-eight hours. The actual time was eight hours.

Meetings of the Societies, Lectures, &c.

[WEDNESDAY, MARCH 21st.]

ROYAL MICROSCOPICAL SOCIETY (29 Hanover Square, W.)—8 p.m. Papers:—Mr. C. F. Rousselet: A Contribution to our Knowledge of the Rotifers of South Africa.—Mr. E. M. Nelson: On the Revolving Limbs for the Telescope and the Microscope.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Arris and Gale Lecture:—Mr. J. H. Watson: The Viscosity of the Blood.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chemist Street, W.C.)—4 p.m. Mr. H. L. Barnard: Clinique. (Surgical). 5.15 p.m. Lecture:—Dr. R. Jones: Evolution in the Treatment of Mental Diseases.

THURSDAY, MARCH 22nd.

CHILDHOOD SOCIETY AND THE BRITISH CHILD-STUDY ASSOCIATION (Parkes Museum, Margaret Street, W.)—8 p.m. Lecture:—Mr. J. C. Medd: Proportion in Education. (Arranged by the British Child-Study Association.)

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.)—8.30 p.m. Harveian Lecture:—Dr. J. S. R. Russel: Myelitis (illustrated by lantern slides).

ROYAL COLLEGE OF PHYSICIANS OF LONDON (Pall Mall East).—5 p.m. Lumsden Lecture:—Dr. D. Ferrier: On Tabes Dorsalis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chemist Street, W.C.)—4 p.m. Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m. Lecture:—Dr. C. R. Box: Congenital Diseases of the Heart.

FRIDAY, MARCH 23rd.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.)—8 p.m. Clinical Evening for the Exhibition of Clinical Cases. Patients in attendance from 8 p.m. to 9 p.m.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Arris and Gale Lecture:—Mr. S. W. Curl: The Arterial Pulse, its Physiology and Pathology.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chemist Street, W.C.)—4 p.m. Dr. D. Grant: Clinique. (Ear.)

Vacancies.

Bristolington House Private Asylum, Bristol.—Assistant Medical Officer. Salary £160 per annum. Applications to the Resident Licenses.

London County Asylum, Colney Hatch, New Southgate, N.—Fourth Assistant Medical Officer. Salary £180 per annum, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk to the Asylums' Committee, Asylums' Committee Office, 6 Waterloo Place, S.W.

Metropolitan Borough of Battersea.—Medical Officer of Health. Salary £200 per annum. Applications to W. Marcus Wilkins, Secretary, Town Hall, Battersea, S.W.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-upon-Trent.—Senior House Surgeon, Salary £100 per annum, with furnished apartments, board, and washing. Applications immediately to the Secretary and House Governor.

West Norfolk and Lynn Hospital, King's Lynn.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications immediately to the Chairman of the Hospital.

Valkenberg Asylum, near Cape Town.—Assistant Medical Officer. Salary £250 per annum, with board, washing, and lodging. Applications to the Agent-General for the Cape of Good Hope, 10 Victoria Street, London.

Surrey County Asylum, Brookwood, near Woking.—Third Assistant Medical Officer. Salary £120, with board, lodging, laundry, and attendance. Applications to the Medical Superintendent.

Manchester Royal Infirmary.—Resident Medical Officer at the Infirmary. Salary £150 per annum, with board and residence. Applications to W. L. Saunder, General Superintendent and Secretary, Manchester Royal Infirmary.

Manchester Royal Infirmary.—Resident Medical Officer at the Convalescent Hospital, Cheaseid. Salary £150 per annum, with board and residence. Applications to W. L. Saunder, General Superintendent and Secretary, Manchester Royal Infirmary.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer for the Casualty Department. Salary £100 per annum. Applications to W. M. Wilcox, Secretary.

Appointments.

BLAKISON, ARTHUR ALEXANDER, M.R.O.S., L.S.A., Medical Officer of Health of Glastonbury (Somerset) for three years.

BROWN, R. B., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Howden District of the county of York.

BRUNWIN, ALAN DEED, M.B., B.C.Cantab., House Surgeon at the Denbighshire Infirmary, Denbigh.

DALBY, AUGUSTUS WILLIAM, L.R.C.P., L.R.C.S.Edin., Medical Officer of Health for the Frome (Somerset) Rural District Council.

EDMUNDS, EDGAR, F., M.B., B.S.Durh., House Surgeon at the Chester General Infirmary.

FAIRBANK, H. A. T., M.S.Lond., F.R.C.S.Eng., Assistant Surgeon to the Hospital for Sick Children, Great Ormond Street.

FLITCROFT, THOMAS E., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Medical Officer to the Newcastle-on-Tyne Dispensary.

FOREMAN, BERRY JOSEPH, L.R.C.P. and S.Edin., House Surgeon at the Rawcliffe Hospital and Dispensary, Chorley, Lancs.

LACE, FREDERICK, F.R.C.S.Eng., F.R.C.P.Lond., an Honorary Consulting Surgeon to the Chippendale Cottage Hospital.

MUNRO, W. E., M.B., M.S.Aberd., Certifying Surgeon under the Factory and Workshop Act for the Burghead District of the county of Elgin.

PRICE, D., M.R.O.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Castle Cary District of the county of Somerset.

RANDOLPH, CHARLES, M.R.C.S.Eng., L.R.C.P. and L.M.Edin., Medical Officer of Health for the Wellington (Somerset) Rural District.

SAWYER, JAMES, E. H., M.D.Oxon., M.R.C.P.Lond., Physician to Out-patients at the Birmingham and Midland Free Hospital for Sick Children.

STOLTENFOTH, C. S., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Stokenchurch District of the County of Buckingham.

WALLIS, E. WHISHAW, L.D.S., R.C.S.Eng., Assistant Dental Surgeon to the Italian Hospital, Queen Square, London.

Birth.

COPEMAN.—At 24 Marine Parade, Brighton, the wife of Alfred Heathcote Copeman, M.A., M.D., M.R.C.S., L.R.C.P., D.L., of a son.

Marriage.

MATTHEWS—BELL.—On March 14th, at St. Peter's, Stockton-on-Tees. Craufurd Tait Matthews, M.B., Ch.B., of Huddersfield, son of the Rev. J. H. Dudley Matthews, Rector of Purley, Berks, to Dora, youngest daughter of J. Hyslop Bell, Esq., J.P., St. Fillan's, Stockton-on-Tees.

Deaths.

HEDGES.—On March 13th, at Rutland House, Leighton Buzzard, John Alexander Hodges, M.R.C.S.Eng., L.R.C.P., aged 65 years.

PERKIN.—On March 16th, at Bulawayo, South Africa, Robert Frederick Thornton Perkin, M.R.C.S., L.R.C.P., and L.M., elder son of the late Captain H. Hilton Perkin, aged 45.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXXXII.

WEDNESDAY, MARCH 28, 1906.

No. 13.

NOTES AND COMMENTS.

The International Medical Congress. THE life of the medical profession is strenuous and exacting, and no man better deserves his holiday. Nay, more than that, there is no profession in which the occasional rest of mind and body is more absolutely essential to the long continuance of a high standard of work. Barristers spend three months over their long vacation; solicitors have to take what they can get, and so have medical men. Under these circumstances there is a peculiar value attached to the occasional colonial jaunt of the great medical associations and to the international scientific meetings held in various parts of the world. Lisbon is now a centre of attraction to medical visitors from many countries. Those who can spare the time can have a thoroughly enjoyable yachting cruise. The "Booth" line have control of hotel accommodation at Lisbon, and offer the whole trip of twenty-eight days at an inclusive fare of £22.

Oporto, Lisbon, Cintra. ANOTHER excellent plan is that which takes the visitor to Lisbon and keeps the ship as his headquarters. The last visit of the International Medical Congress found Lisbon sadly lacking in hotel accommodation, a deficiency that will be this year more than remedied by utilising ships. Apart from the scientific aspect of the meeting, the country itself is interesting and picturesque. There is much to see in the old Roman and Moorish city of Oporto, which everyone will do well to linger at for a day or two *en route*. Then, again, there is Cintra, of all places one of the most romantic and beautiful. The official language of these meetings is French. In future it is proposed to hold these great International Congresses at intervals of five years instead of three. As we all know, it is possible to have too much of a good thing.

Life Insurance without Medical Examination. THE "Sun" is one of the oldest of British life insurance offices, and holds a deservedly high reputation. Of late years, however, its policy in offering to insure applicants without medical examination, is hardly consistent with the highest ethical standards. First of all, it is to inflict an injury upon medical men, for it constitutes the life insurance officer into a species of unqualified medical detective. On the other hand, applicants find themselves vastly deluded if they go to the "Sun" with a family or personal history of any of half a dozen maladies—pleurisy, for instance—for they are at once haled off to a medical man for examination. Only those

candidates who look robust and can answer an exhaustive examination paper in a satisfactory way can escape the doctor. So that the "Sun" escapes paying fees for the examination of a certain number of apparently sound lives, while in all cases where the least doubt is suggested they have a medical reference like all other offices. What is the morality of this transaction?

The Nervous Insurance Applicant.

FOR some reason or other, as all medical examiners know, the applicant for insurance in nine cases out of ten gets a "stage fright." There can be no reasonable doubt that a certain percentage of persons never insure at all because of their dread of the medical ordeal. This insurance-phobia—to coin a word—may be foolish, but it is none the less real, and the "Sun" has treated it in a businesslike way, and made capital out of it. If that office can advance sufficiently sound arguments to uphold its position, well and good. Recently the office in question has issued to medical men a pamphlet which appears to us to be simply adding insult to injury, for it not only shows the number of persons attracted by the non-medical examination scheme, but also insinuates that medical men approve both of the *suggestio falsi* proffered to the public and of the injury done to the medical profession. The attitude may be gathered from the following extract from the pamphlet already alluded to, published under the title "More Signs of the Times." It occupies the next paragraph in this column, and needs no comment.

Signs of the Times. "Sun" Edition. "The Society's plan of assurance without medical examination has been in operation for upwards of four years, and I am now authorised

to tell you that it has proved satisfactory to the Society and attractive to the public, upwards of 7,500 policies having been issued. I am also pleased to be able to say that its aims and objects having been recognised, it has commended itself to many members of the medical profession throughout the country, for it has been shown to be not inimical to their interests, but rather calculated to relieve them from the difficulty so often felt of doing justice to all concerned when examining and reporting on the life of a patient or neighbour. The Society's system is novel and framed to meet popular requirements, but, in so far as it relies upon the medical attendant's confidential report of the applicant's medical history it reverts to an old and successful practice."—*Signs of the Times.*

LEADING ARTICLE.

PUBLIC NEWSPAPERS AND QUACK ADVERTISEMENTS.

THE question of the publication of fraudulent quack advertisements in lay newspapers has reached the House of Commons. Last week a question elicited from Mr. Herbert Gladstone an opinion to the effect that the evil results arising from the sale of quack medicines would be better met by the spread of education than by Government prosecutions for fraud. We confess that to us the principle thus laid down is somewhat of an Egyptian mystery. Government does not wait for ideal intellectual and physical developments to protect the community against—let us say—garotters, postage-stamp forgers, and long-firm swindlers. Why, then, put off dealing with the equally pernicious set of quacks and quack medicine vendors, whose roguery inflicts incalculable damage upon the health, happiness, pockets, and even the lives of His Majesty's subjects? Our contemporary, *Truth*, takes a sensible editorial view of the question in the following passage in its issue of March 22nd, 1906:—"It seems to me that if a man commits a fraud by means of a quack medicine, he is as fit a subject for a Government prosecution as the man who commits a fraud by selling adulterated food or shines in bogus companies. I should like to think that the Home Secretary is right in expecting that the spread of education will render people less likely to fall victims to this particular form of fraud, but I am sorry to say that I see no evidence for expecting much in that direction." The underlying sentiment of our contemporary with regard to quack medicines is excellent. Let us see how his theory works out in his own practice. The first objectionable thing that catches our eye in the above-quoted issue, is a notice in a column headed "Girls' Gossip," praising Mrs. John Strange Winter's "Hair Food." Knowing the ways of such writers, we turned to the advertisement columns and there found a carefully-worded notice of the "food," describing it as a "rich stimulant and scurf remedy." As a matter of scientific fact, there is no such thing as a hair food, and any preparation claiming to nourish the hair directly is based on a physiological impossibility. In other words, a "hair food" is worthless, and the Editor of *Truth* is receiving money for helping to push the sale of a self-proclaimed sham. Following the hair food advertisement (page 722) is an advertisement by one "Mrs. Adair," who sells a variety of wares of a transparently fraudulent nature. There is a "Patent Ganesh Forehead Strap," sold at £1 5s. 6d., to cure the deep lines between brows and about eyes; it is "stuffed with powdered herbs most healing and beneficial" (*sic*). Then come "Ganesh Muscle Oil," to fill out hollows and remove lines, at £1 10s. 6d.; the Ganesh Eastern Cream, the greatest skin food and muscle producer in the world, at 10s. 6d.; the "Ganesh Diable Skin Tonic," at £1 1s. 6d., to close the pores and

cure puffiness under the eyes; and, lastly, the "Ganesh Chin Strap," at £1 1s. 6d., made of "a specially prepared silk elastic steeped in a preparation known only to Mrs. Adair, is a certain cure for double chins, and takes away the line running from the mouth to the chin." All this is sheer arrant quackery of the worst and most fraudulent description, which, under any decently framed and decently administered Medical Act or Pharmacy, would not be permitted to exist for a week in any sane civilised community. Surely so accomplished a man of the world as the Editor of *Truth* need not await the spread of a more general education on these matters to learn that nothing short of a radical surgical operation is any cure for double chins and wrinkles and other natural and acquired lines and furrows about a face; that no oil can remove such lines; that no cream can feed the skin and produce muscle; that no tonic can cure puffiness under the eyes; in short, that the whole of the Ganesh remedies are obviously unable to perform what they profess to bring about, in other words, they are fraudulent. But *Truth*, the great *ensor morum* of Society, takes money for advertising Mrs. Adair's worthless nostrums. Without advertisement her nefarious business could not exist. *Truth*, therefore, is, in point of fact, assisting in the creation and the maintenance of a traffic in trade nostrums of an obnoxious nature, and is, moreover, sharing the profits. On the whole, we have pleasure in acknowledging that the columns of *Truth* are remarkably clear from pernicious advertisements. What can we hope for if the mirror of social ethics be itself sullied? Our respect for the journal in question has been frequently expressed, and is sincere enough to lead us to hope that in future a more rigorous attention will be given to the exclusion of objectionable patent medicines from its advertisement columns.

NOTES ON CURRENT TOPICS.

Risks and Uses of Ethyl Chloride as an Anæsthetic.

SINCE ethyl chloride was introduced to the profession in these countries in 1902 by Dr. McCardie and others it has rapidly increased in favour as an anæsthetic for short operations. The reasons for this are not far to seek. It is easy of administration, rapid in its action, portable, and not unpleasant to the patient. The consequence has been that its adoption has taken place a little faster than the growth of the necessary skill in using it. Coming to us with a reputation of entire safety, it has naturally enough been taken up by dentists and others almost to the exclusion of the use of nitrous oxide. The result has been that not a few fatalities have occurred, and at the present moment there is a revulsion of feeling which tends to drive it even from its legitimate uses. There is little doubt that there is no justification for the employment of ethyl chloride where nitrous oxide anæsthesia will suffice, as, for instance, in nearly

all dental operations. In children, however, nitrous oxide is not a trustworthy anæsthetic, and in them ethyl chloride is indicated. On the other hand, it is hardly to be relied on as a substitute for ether in prolonged operations, since changes taking place during its use occur so rapidly as to leave little time to guard against serious conditions. In ordinary "good" subjects, without fatty heart, and in alcoholics, it is a convenient and safe preliminary to ether. Whatever plea may be urged in favour of the administration of nitrous oxide by other than medical men, we entirely agree with Dr. McCardie in his view that ethyl chloride is an anæsthetic which no one should employ who is not prepared to perform immediate tracheotomy or to take such other steps of urgency as serious spasm or rigidity may require.

Chinese Labourers and Sanitation.

WHILE the question of Chinese labour is agitating the public mind so deeply, it is interesting to note that a special report on the sanitary circumstances of the Chinese employed within the Johannesburg municipal area has just been issued by Dr. Charles Porter, the Medical Officer of Health for that city. From this report it appears that certain recommendations of the Transvaal Medical Society with regard to the living space, ventilation, lighting, and treating of the labourers' quarters have been adopted, and that consequently the Chinamen are in clover, enjoying not only the amenities of clean, well-aired rooms, but such hitherto unknown luxuries as hot baths, steam cooking ranges, and expert cooking. The food is excellent in quality and generous in quantity; rice and salt in unlimited amounts, half a pound of fresh meat and bread and twelve ounces of fresh vegetables being supplied daily. Medical attendance, too, is provided, the choice of a Chinese or English doctor being afforded, and well-equipped hospitals are ready to receive all the sick. Dr. Porter, recalling his English experiences, expresses an emphatic opinion that the conditions under which the Chinese live in their compounds are very much superior, as regards housing, food, and payment, to those which the unskilled white labourer at home, either in town or country, can command. It will be satisfactory to those to whom the good name of the Empire is dear to know from the testimony of a competent medical official that the Chinese are so well provided for, but the report cannot but fail to raise the question why the unemployed at home were not given the chance of enjoying these Elysian advantages.

Clinical Pathology in its Relation to Medicine and Surgery.

MR. MAYO ROBSON discussed a subject of some interest to the profession in his recent address to the Bristol Medical Society. The day has passed when each physician or surgeon can himself make the investigations in clinical pathology necessary for the proper diagnosis and treatment of the diseases of his patients. He can neither afford the time required for learning the elaborate technique

of the modern laboratory nor can he, in the course of his practice, even were he possessed of the requisite methods, set aside sufficient time for the conduct of the various investigations as they are required. It is necessary for him, therefore, to have at hand the assistance and advice of a skilled pathologist, and it is a question at the present moment in what way such assistance and advice can best be obtained. Mr. Mayo Robson rightly points out that the system which has held up to the present of obtaining reports from a clinical laboratory at so much a report is lowering to the dignity of the profession and derogatory to the responsibility of the pathologist. He is right, too, in believing that the complete severance between the clinician and the laboratory worker, inherent in this system, is a serious disadvantage to the value of the work done. If a pathologist can give aid to a physician or surgeon by his examination of a morbid specimen, the physician or surgeon can on the other hand give him help in the formation of his opinions by full information as to the clinical aspects of the case. Mr. Robson looks to the springing into being of a new race of consultants—the consulting pathologist, who will be willing not merely to examine a specimen and give a report, but to meet a physician or surgeon at the bedside beforehand, and after examination, not merely of those specimens the clinician may think of submitting, but of all that he himself, on a full consideration, thinks of demanding, furnish his opinion. We believe with Mr. Robson that some such plan as this is required in order to bring together two branches of work, either of which is imperfect without the other.

Liverpool School of Tropical Medicine.

THE completion of seven years' work finds the Liverpool School of Tropical Medicine in a position of which it and its promoters may indeed be proud. The school is an established success. It is well and comfortably housed in the laboratories presented by Mr. William Johnston; it has command of a "Tropical" ward at the Royal Southern Hospital; and it is staffed by a band of brilliant workers. In the short time since it came into being it has equipped and sent out no less than sixteen expeditions to warm climates to investigate disease or to advise the local authorities in preventive measures, and it has issued twenty-one publications on tropical pathology and hygiene. The energy and enthusiasm of the school and its staff seem sufficient to carry them through all difficulties, financial and other, and perhaps it may be accounted as one of their greatest triumphs that they have succeeded in getting £500 a year for five years out of the Government. The Liverpool merchants and citizens, among whom Sir Alfred Jones stands conspicuous, have shown a commendable spirit of local patriotism by the support they have given to the school, but needless to say, although the annual report does not contain more than a reminder that funds are short, the work could be

much extended and developed if more generous donations were forthcoming. It is highly appropriate that a part of the importance of Liverpool, which trades with so many unhealthy regions, should possess its own School of Tropical Medicine, but there is none the less an obligation on all imperially and humanely-minded people to help forward its good work.

Snails, Dietetic and Therapeutic.

ONE of the stock subjects wherewith the journalist stimulates the jaded curiosity of nineteenth century mankind, is that of snails as food. As a deep student of human nature, the penman knows the thrill that runs through the mind and body of the average citizen when he is advised to eat some tabooed food such as snails, horseflesh, or frogs' legs. Now, apart from prejudice those food-stuffs are one and all cheap, nourishing, and toothsome. They are all, for instance, prized by our French neighbours, who know a good eatable when they see it. It would certainly be of service to our rural population were they to adopt snails as an article of ordinary food. Meanwhile the newspaper man is making reams of copy out of the ancient and modern history of the edible snail. Many cures, especially of consumption, are attributed to snails. Their value, as with cod liver oil, is probably due simply to their nourishing qualities. A correspondent to a London journal tells how at six years of age he was "cured" of hopeless consumption by being sent out into the fields every morning, where he had to eat two dozen dew snails. This is clearly a sagacious anticipation of the open-air cure, with its forced exercise and feeding. The writer says he is now between seventy and eighty years of age, and has not drunk a glass of cold water for thirty-five years. He omits to state what the latter method has "cured."

Police Methods at Leeds.

THE Leeds police-court proceedings, arising out of the summons of five medical students, have taken an extraordinary turn. The magistrates dismissed the summons, whereupon a counter-charge of assault was laid against the police. It will be remembered that the original plaintiffs were turned out of the Tivoli, where they had demonstrated against the notorious "Electricity Emperor," "Dr." Walford Bodie. The evidence in the counter-charge alleges official conduct resembling that of Russia rather than of England. It appears that the four students were charged with disorderly conduct in the street half an hour after being ejected from the hall. So far as we can gather, there was no evidence whatever of outside disorderly conduct obtainable from the police, who had secured the names of the men inside the hall. Another extraordinary allegation is that the superintendent refused the names of the constables accused of assault, and referred the prosecuting solicitor to the Chief Constable. So much delay resulted that a summons was taken out by de-

scription. Other extraordinary allegations were made against the police. The Stipendiary has reserved judgment for a fortnight. If the police methods of Leeds even remotely resemble the picture drawn by the prosecution, the citizens may thank "Dr." Bodie for having by accident done them one good act in drawing attention to so intolerable a system.

Prosecution of "Professor" Richard.

THE police prosecution of a "medical electrician" at Wolverhampton, has brought forth a shoal of witnesses and a mass of extraordinary evidence. As the case is still under investigation, comment is not permissible. At the same time, there can be no objection to pointing out that Richard has for years past been relentlessly exposed by *Truth*. Further, the "Professor's" operations have been carried out on a scale truly Napoleonic for last week no less than twenty-two specific charges were preferred against him of obtaining money under false pretences. The charges presumably cover only a portion of the electrical treatment business, and as they involve fees amounting to £270, the total receipts must have represented an income that many a gifted medical specialist would envy. Incurable deafness and blindness were treated at fees ranging from three to thirty guineas. The hopeful fact about this prosecution is that the police are acting on general penal laws apart from the Medical Acts.

Military Hygiene.

Now that real Army reforms are in the air it is a hopeful sign that military officers have been induced to take interest in matters of military hygiene. We are reminded of a lecture on the subject given by Major Davis, R.A.M.C., at the United Service Institution a few months ago, before an audience that included a good array of officers of both branches of the Service. The lecturer did not break much new ground, but pointed out that, in view of the fact that the Japanese lost 57,000 men from wounds in their late war as against 15,000 from disease, whereas our troops in South Africa had 400,000 admissions to hospital from disease to 18,000 in respect of wounds, something radical was wrong. The two chief remedies he proposed were the formation of a special sanitary corps to arrange and supervise all hygienic matters on a campaign, and systematic instruction of military officers and men in the preservation of health on service. Authorities will agree that these two proposals are at the root of all hygienic reform in the Army, and we were correspondingly surprised at the time to find Surgeon-General Keogh, Director-General of the Army Medical Corps, opposing the formation of a special sanitary corps. Possibly he had sound reasons for that attitude, or perhaps he was prepared to advance a sounder alternative plan. From our point of view, however, there is little doubt that each army doctor should be well trained in the prevention of disease, but it is

of the greatest importance to have in addition a corps of experts specially organised for preventive work during a campaign. No doubt military officers are opposed to such a change, but we hope the Director-General will see his way to some such reform.

Medicine in Korea.

If trade follows the flag, as Mr. Rhodes once said, medicine perhaps more than any other single calling welds Empires. At any rate, no civilisation of a modern character can advance far without the aid of scientific medicine, and now that Korea is ceasing to be a stock puzzle at geographical examinations and is now coming to take its place in the comity of nations, the need of medical education is being experienced. From a letter by Dr. Vinton in the *Medical Record*, it appears that Korea has hitherto followed in many respects the practice of China with regard to its medical arrangements. Thus, practitioners are paid by results and not according to the number of visits—a system which may have some advantages from the point of view of the public. Payment is usually moderate even for a complete cure, and it is usually made in kind, the successful physician being rewarded with rice, eggs, poultry, nuts, fruit, and seaweed; occasionally a coin is forthcoming, and a pig or two, or even a bullock, may be added if great gratitude is stirred. The most trustworthy source of income for the physician, however, is the vending of medicines; these he dispenses himself, and as he charges so much per ingredient, one is not surprised to hear that poly-pharmacy is on the ascendant. In Korea, representatives of the pathological school of therapeutic Nihilists are as rare as white black-birds. The old order, however, is changing, and American pioneers are already attempting to establish a native school of medicine. Gray's "Anatomy" has been partly translated into the vernacular for its use, and other standard works are being undertaken. We trust they will be duly appreciated by the local profession.

PERSONAL.

LORD ROTHSCHILD has become President of the Royal Dental Hospital, London, *vice* the late Duke of Cambridge, and Sir Frederick Treves, Bart., has been nominated consulting surgeon to the same Institution, *vice* Mr. Christopher Heath, deceased.

DR. JOHN C. M. M'VAIL, Medical Officer of Health for the Counties of Stirling and Dumbarton, has been appointed "Lane Lecturer" for 1906 in the Cooper Medical College, San Francisco. This lectureship was founded some ten years ago and consists of ten lectures delivered on five consecutive days in August, one in the morning and one in the evening of each day.

WE understand that Lieutenant-Colonel J. M. Irwin, Royal Army Medical Corps, now on the Aldershot Staff, has been nominated for the appointment of Assistant Director-General of the Army Medical Service.

MISS SIDNEY BROWNE, the matron-in-chief of Queen

Alexandra's Imperial Military Nursing Service, retires into private life early next month. She holds many decorations, including the Egyptian medal and clasp and the Khedive Star, and the King's and Queen's medal for South Africa.

IN connection with the next year's forthcoming second International Congress on School Hygiene, to be held in London, a meeting will be held, under the Presidency of the Duke of Northumberland, at the University of London on Friday, March 30th, at 5 p.m.

HIS MAJESTY THE KING has conferred a Knight Commandership of the Royal Victorian Order upon Lieutenant-Colonel H. H. B. Charles, I.M.S., Surgeon to the Prince of Wales in India.

SIR LAUDER BRUNTON will preside over the Second International Congress on School Hygiene, to be held in London from August 5th to 10th, 1907.

DR. A. H. F. BARBOUR has been appointed Lecturer on Gynæcology, both systematic and clinical, to the University of Edinburgh to fill the vacancy caused by the resignation of Dr. Berry Hart.

DR. J. M. STIRLING has been appointed to the vacant chair of Ophthalmology in McGill University. Dr. Stirling graduated in Edinburgh, where he was house surgeon to Dr. Argyll Robertson.

THE name of Mr. W. B. Taylor, M.R.C.S.Eng., has been placed on the Commission of the Peace for the County of London.

LAST week Professor Sims Woodhead was entertained at a banquet given by the Corporation of Glasgow in his honour as President of the Temperance Collegiates' Association.

It is widely stated that Miss Olga Nethersole will retire from the stage in eight years' time or sooner, and devote her life to fighting tuberculosis. She has lately, says a Laffan's New York message, taken up the study of medicine, in which she became interested through Sir Alfred Frupp.

THE distribution of prizes at the close of the winter session of Anderson's College Medical School was made last week to the successful students by the Lord Provost of Glasgow and Mrs. Bilsland.

THE wills of three members of the medical profession have been proved during the past few days, that of Deputy-Surgeon-General Sir Joseph Ewart, of Brighton, under the sum of £33,263, that of Dr. A. B. Paterson, late of Beaumont Street, London, W., under £65,271, and that of Mr. Wm. Moxon, J.P., M.R.C.S., L.S.A., late of Northampton, under £48,042.

PROFESSOR T. C. HAYES, M.D., having resigned the Chair of Obstetric Medicine, in King's College, London, the Council have appointed Dr. John Phillips as his successor. Dr. G. F. Still has been elected Professor of Diseases of Children at the same institution, Dr. W. E. Dixon to the Chair of Materia Medica and Pharmacology, and Dr. Frank E. Taylor Demonstrator of Bacteriology.

FIVE of the Scarborough Board of Guardians' medical officers expressed themselves unreservedly in favour of the inclusion of phthisis in the Compulsory Notification of Diseases Act, 1899. The board, which consists of seventy-two members, decided almost unanimously to support a petition to the Local Government Board in favour of the recommendation.

A CLINICAL LECTURE

ON

ACQUIRED FLAT-FOOT—TALIPES VALGUS.

Delivered at the Royal Victoria Hospital, Belfast, February 16th, 1906.

By A. B. MITCHELL, M.B., F.R.C.S.I.

GENTLEMEN.—When a young person, æt. between 14 and 20 (though I do not mean to exclude other years) complains of pain in one or both feet, which gets worse towards evening and is relieved by rest, be sure to examine carefully for flat-foot. This condition is very common, and is very frequently overlooked, especially in the early stages, when, though pain may be very intense, deformity in the sense of flattening of the arch, may be slight or even absent.

The pain from which these patients suffer is often hastily regarded as rheumatic, and with some justice, for this deformity is frequently the direct result of acute rheumatism. So common is this association that when you meet with a case of flat-foot you must never neglect to examine the heart for evidence of that disease.

A young man, a striking example of this combination, was a patient in one of our medical wards about a month ago. He was admitted for heart disease, and his feet were markedly flattened.

Omitting all reference to the paralytic variety, I shall confine my remarks to what is known as static flat-foot. It occurs most commonly in young people whose muscular tone is below par, whose vitality has been lowered by improper nourishment, whose work has not uncommonly involved prolonged standing, it may be, in over-heated, imperfectly ventilated rooms. Sometimes they have a rickety diathesis, at others the starting point of the trouble is a direct injury—Traumatic flat-foot; whilst one of the most severe cases I have seen was due to Gonorrhœal Rheumatism. These young people, as the result of prolonged standing in faulty positions, exhibit signs of muscular exhaustion. The muscles which support the ligaments on the sole of the foot relax their vigour, the most important in this respect being the tibialis posticus, which, as you know, has a very extensive attachment to the bones of the foot. Soon the inferior calcaneo-scapoid and other ligaments, deprived of their normal support, begin to yield and stretch. A curious rotation takes place at Chopart's joint; the head of the astragalus comes downwards and inwards, projecting on the inner border of the foot, the scaphoid is pushed forward and rotated so that its tuberosity also projects. In this rotation the anterior part of the foot partakes, so that the sole is everted, its outer border raised, and the peronei tendons become prominent.

If you examine this bony specimen, which, through the kindness of Professor Symington I am enabled to submit for your inspection, you will observe how the bones become affected in advanced cases. Note especially—

1. The astragalus is rotated so that its head is directed too much inwards and that its trochlear surface looks upwards and inwards instead of directly upwards.

2. The os calcis is rotated so that only its inner tuberosity rests on the table, its outer surface looks obliquely upward and has come into contact with the tip of the outer malleolus, and a new articular facet has been formed on each of these bones.

3. The position of the scaphoid and the rotation at Chopart's joint.

If you now examine this patient you will observe that she walks badly, with a characteristic stiffness and want of spring. She states that towards evening she gets worse, and that she gets some puffiness about her ankles, especially the right. For the past two months walking or standing has become more and

more painful, till she has been compelled to give up work. Her right foot is everted and rigid, the outer border is raised, the inner malleolus is very prominent, the outer much less prominent than in the sound foot. On the inner side the head of the astragalus projects, but the arch is only slightly flattened. Her chief complaint is of pain. The foot is so stiff that you cannot invert the sole nor completely extend the ankle.

The case is an example of spastic flat-foot, a very troublesome form. Three other points are to be noted :

1. If we smear the sole of her foot with ink and ask her to stand on a sheet of clean paper we get a foot-print which shows that too much of the sole touches the ground; but hers is not a very striking print, and, indeed, this test so commonly employed is of little value in the early stages of the disease.

2. If we draw a triangle on the sole of her foot by joining the centre of the heel with the head of the first and fifth metatarsal bones and a transverse line between these latter points—Von Meyer's triangle—you will see that a perpendicular through the centre of articular surface of the astragalus would fall almost half an inch inside of the inner border of this triangle, whereas in the normal foot it falls on the line or just outside it.

3. Mr. Golding Bird has pointed out that the joint between the first metatarsal and internal cuneiform bones corresponds exactly to the middle of the inner border of the foot; that in cases of flat-foot the inner border is increased in length, and that this increase is entirely in the posterior half of this border the anterior half remaining normal. You will note that in our patient this cannot be demonstrated. It is, I think, only applicable to advanced cases, but I have more than once found over half-inch increase in the posterior half.

Time only permits a very brief reference to the question of treatment.

1. It is very desirable to arrange if possible for a change of occupation which will involve less standing.

2. Attention must be paid to the general health; correction of anæmia or similar condition.

3. Pain and spasm is to be relieved by complete rest, preferably in bed.

4. If, as is the case in the patient I have just shown you, pain and spasm persist in spite of rest, an anæsthetic must be administered, the foot freely manipulated, and encased in plaster of Paris in the *varus* position for two or three weeks.

5. The next thing is to provide some artificial support for the weakened arch. The simplest and most efficient is to have the boot made without an instep, the inner border of the sole running straight to the heel; at the same time the inner side of the sole and heel is made thicker than the outer, so that patient must walk on the outer border of the foot.

Any of the special pads or supports I now exhibit—of which Whitman's brace, though uncomfortable at first, is decidedly the most efficient—may be ordered.

6. Systematic exercises calculated to strengthen the calf muscle should be vigorously carried out, *e.g.*, the feet being slightly adducted, the patient standing erect should slowly raise the heel till the weight of the body is supported on the balls of the toes, maintain this position for a moment, and then slowly come back to the original position; the exercise to be repeated till a slight sense of fatigue is experienced. This

should be done several times daily. Massage is very beneficial where it can be obtained.

For the more severe cases operation may be considered; but I advise you not hastily to recommend active interference. The results even in the hands of the best surgeons are often disappointing, convalescence is slow, and three to four months must elapse before the full weight can safely be borne on the foot. Several procedures are in vogue, a fact which shows that none is entirely satisfactory. I shall merely indicate a few:—

1. Stokes removes a wedge from the neck of the astragalus.

2. Ogston excises the astragalo-scapoid joint, and secures permanent ankylosis.

3. Many surgeons remove a wedge from the inner border of the foot without special regard to the bones removed.

4. Where the valgus has followed fracture of the tibia and fibula, Trendelenburg performs osteotomy on these bones.

5. A very ingenious suggestion has recently been made by Wilson and Patterson ("American Medicine," Vol. IX., May 6th, 1905). Having excised the astragalo-scapoid joint, they divide the tendon of the extensor proprius pollicis, the proximal end of which is brought down over the inner border of the foot, carried through a hole specially drilled in the tuberosity of the scaphoid, and secured by sutures; the tension on the tendon being sufficient to ensure its acting as an additional support to the newly-formed arch. They claim that the results are satisfactory and permanent. The method certainly seems worthy of a trial.

None of these operations is very simple. All of them involve a compound fracture. The foot is difficult to sterilise, and suppuration is, I fear, more frequent after operation than is generally acknowledged. Therefore, I advise you only to fall back on them when simple measures have failed, and when your patient is seriously inconvenienced by the deformity.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of the journal. The lecture in next week's will be by William Alexander, M.D., F.R.C.S., Surgeon to the Royal Southern Hospital, Lecturer on Clinical Surgery in the University of Liverpool, "On Cancer of the Uterus."

ORIGINAL PAPERS.

NOTES ON TWO RARE CONDITIONS MET WITH IN THE PELVIS DURING OPERATION.*

By HENRY JELLETT, M.D., F.R.C.P.,
Gynaecologist and Obstetric Physician to Dr. Stevens' Hospital,
Dublin.

I DESIRE to bring to your notice two abnormal conditions which occurred in my practice at Dr. Stevens' Hospital, Dublin, that are of sufficient rarity to be of interest.

The first case is one of anatomical, rather than of clinical, value. M. S., æt. 26, was admitted to Dr. Stevens' Hospital on October 19th, 1905. She stated that she had been married five years and had had two children. The second of these was born three years ago, and her illness dated from that time. Apparently, she suffered after her confinement from an attack of pelvic infection, as a result of which a pelvic abscess had been opened and drained in another hospital. After this, her health improved for a time, but the symptoms had gradually returned until they became so serious as to require further advice.

On bi-manual examination, the uterus was found to occupy an almost vertical position in the pelvis, and was slightly displaced to the right side. Douglas's pouch was occupied by two swellings, each the size of a small orange. The right swelling appeared to contain some fluid. A diagnosis of double salpingo-oophoritis was made.

On September 22nd, I opened the abdomen, and found the condition of the pelvic organs to be very much as described. The steps of the operation were of no great interest, and I may sum them up by saying that the appendages were freed from their adhesions with considerable difficulty; that between them lay a cavity containing pus, which escaped during the operation; that the pelvic tissues were extensively infiltrated on the right side between the uterus and the pelvic wall; and that, under the belief that I was dealing with a tuberculous case, I removed this infiltrated tissue as well as some enlarged pelvic glands; and that, then, in consequence of the diseased condition of the uterus, my belief in the tuberculous nature of the case, and the necessity for obtaining free drainage, I removed the uterus by Doyen's method, opening the anterior cul-de-sac first. The pelvis was then plugged with iodoform gauze and drained into the vagina.

FIG. 1.—Diverticulum coming from Pelvic Colon.

I now come to the interesting feature of the case. When I opened the abdomen in the first instance, I noticed the presence of a tube running from the large intestine into and between the enlarged appendages in Douglas's pouch. I assumed this tube to be the appendix, and, as I could not free it from the appendages, I ligatured it and cut it across, intending to return to it subsequently, and, if necessary, remove it entirely. To my surprise, however, on looking for the supposed appendix, at the close of the operation, I found the real appendix and cæcum in its normal place, and in no way involved in the pelvic inflammation. I then looked for the remainder of the tube which I had divided and found that, instead of coming from the cæcum as I had at first assumed, it came from the pelvic colon, which

* Paper read before British Gynaecological Society, March 8th, 1906

crossed the pelvis from left to right. The accompanying drawing, which was made from my description, gives a good idea of its nature. The tube was some two and a half to three inches in length, and about a quarter of an inch in diameter. It possessed a lumen which I presume communicated with the lumen of the pelvic colon, and its walls were structurally continuous with the walls of the latter. I was at the time under the impression that the lower end of the tube was still attached to the uterine appendages, and that it would be available for microscopical examination; but I regret to say that, on subsequent examination of the specimen, it could not be found, and had apparently been rubbed off during the course of the operation.

I have been unable to obtain any explanation or information regarding this rectal diverticulum, either with regard to its origin or to a previous description of a similar condition.

Kelly, (1) in describing Meckel's diverticulum says that it may be found "outside the classic region, either high up (jejunum, duodenum) or low down (cæcum, colon)," but he does not say anything that could be taken as expressing his belief that it occurs so low as the pelvic colon. I may add that the patient made an uninterrupted recovery, and that, on microscopical examination of the removed appendages, no evidence of tuberculous disease could be found.

FIG. 2.—Absence of Left Appendages in Association with Cystic Right Ovary.

The second case which I wish to bring to your notice is of clinical, and, I think I may say, of medico-legal, interest. M. B., æt. 32, but seemed to be æt. 45 at least, was transferred to me by my colleague, Mr. Haughton, on March 21st, 1905. She stated that she had been married for five years, and had had one child fifteen months before in the Rotunda Hospital. She left the hospital in three weeks, but in eight or ten days afterwards was again admitted, complaining of pain and swelling in her left side, her leg, and her thigh. A few days after admission one of the deep veins of the neck

became thrombosed, and apparently there was also a suspicion of thrombosis of a pelvic vein. In addition to these symptoms, her abdomen became distended, owing to the presence of a very large quantity of free fluid, which was found to be due to cirrhosis of the liver. The Master of the Rotunda sent her to Steevens' Hospital to my colleague, Mr. Haughton, who performed a Talma-Morrison operation for the ascites. Previous to the operation, he had tapped the abdomen on five occasions, removing each time about 150 ounces of fluid, and at the operation a further quantity escaped. The patient's condition improved in a marvellous manner, and no further accumulation of fluid occurred, nor has occurred up to the present date (February, 1906). However, in May, 1904, she began to complain of pain in the lower part of the abdomen, and of irregular and profuse menstruation. On examination, the uterus was found to be slightly enlarged, and, on the right side, a firm, rounded swelling corresponding to the right ovary was felt, about the size of a small orange.

On March 29th, 1905, I opened the abdomen and found the right ovary enlarged to some four or five times its normal size, and cystic. I removed it, leaving the tube. On the left side, there were some small and soft adhesions between the intestines and the back of the uterus. I separated these with the object of examining the appendages, but to my surprise I found that the only structure representing them was the stump of a Fallopian tube some half an inch in length. The end of this stump was adherent to part of the small intestine. There was no trace of an ovary and the peritoneum of the broad ligament was absent, save for a small fold corresponding in length to the tubal stump, and adherent to the surrounding structures. On freeing the adhesions, no scarring of the peritoneum could be found. I assumed that the patient had had a previous operation of which I knew nothing, and closed the abdomen. There was no free fluid in the peritoneal cavity. The condition of the pelvis is well shown in the accompanying drawing.

As soon as the patient had recovered from the operation, I made careful inquiries to elicit any history of a previous operation. There was no abdominal or vaginal scar, but still I thought that perhaps a vaginal operation had been performed, the scar of which had disappeared. The patient however, stated in the most definite manner that, save for the operation performed by my colleague, Mr. Haughton, and of a slight operation on her neck at the Rotunda Hospital, she had never been operated upon, and as this statement is substantiated by the absence of all trace of an incision I think it must be regarded as correct.

Excluding, as I do, the removal of the appendages by operation, two explanations of their absence suggest themselves:—either the left appendages were congenitally absent or they were removed by absorption after some form of strangulation had deprived them of vitality. I think the former of these explanations may be dismissed, as it is impossible, in view of what we know of the development of the tube and uterus, to understand a congenital defect which would leave a conical stump of tube half an inch in length projecting from its normal position on a normally developed uterus. With regard to the second explanation, we know that torsion of the pedicle of an ovarian

tumour is of relatively common occurrence, and Veit, (2) Freund, (3) and Breisky (4) have recorded cases of consequent complete disappearance of the tumour. Further, Hirst, (5) in his work on the "Diseases of Women," has a drawing of a specimen, preserved in University Hospital, Philadelphia, which very closely resembles the condition I found in my case, and Ballantyne and Williams (6) have described a case of absence of the outer two-thirds of the tube in association with genital tuberculosis.

In my case, the right tube was considerably elongated, as also were the ovarian attachments, with the result that the enlarged ovary and ampulla of the tube lay in approximation with the cæcum. They were thus in a most favourable state for the occurrence of torsion, and if we assume the missing left tube and ovary to have been in a similar condition we can account for the predisposition to torsion, while the comparatively small size of the ovarian tumour would facilitate its complete absorption. This is, of course, all surmise, but the fact remains that the left appendages have completely disappeared, that the patient had a history of an attack of pain in her left side, and of circulatory disturbance, and that the remaining appendages were at the time of operation in a condition calculated to facilitate torsion.

Martin, of Berlin, (7) endeavours to account for the separation of ovary and tube by a different mechanism to that of torsion. Braun (8) recorded a case which was very similar to mine, and in which all trace of the adnexa on one side had disappeared save the interstitial portion of the tube; and Martin suggests that this result was brought about by the fixation of ovary and tube by adhesions to an intestine or a piece of omentum in such a way that the ligaments were kept on a continuous stretch, and their blood supply gradually compressed and lost. Martin, however, admits that it is difficult to understand how this could occur in such a way as to lead to the occlusion, not only of the uterine blood supply to the broad ligament, but also of the blood supply coming through the infundibulo-pelvic ligament. Klob, (9) in his work on the pathological anatomy of the sexual organs, says that such a condition can occur when, after pregnancy, the ovary and tube become fixed high up in the abdomen, while the uterus gradually descends into the pelvis. I have myself seen a case which fulfilled these conditions. A patient, confined for some weeks, died with symptoms of septic peritonitis. At the autopsy, the uterus was found in the pelvic cavity, with the tubes and broad ligaments running straight up towards the kidneys. On tracing them upwards, the ampullæ of the tubes were firmly fixed in the region of the lower margin of the kidneys, and were surrounded by inflammatory tissue and pus. On further examination the case turned out to be one of tubercular infection. The tubes and broad ligaments were elongated, and it is possible that, had the patient lived, the continual tension on the supplying blood-vessels might have led to the obliteration of the latter. It is, of course, both possible and probable that, in such a case, some remains of ovary would be found at the spot where it had been adherent, and that therefore we should speak of such cases, not as absence of the tube and ovary, but rather as one of *apparent absence*

Whether, to revert to the case before us, such a process as that described by Martin and Klob is compatible with the slight amount of pelvic scarring and of intestinal adhesion that were present in this case is a point on which it is difficult to give an answer. I incline to the view that it is not compatible, and that the more likely explanation is to be found in torsion of the elongated pedicle of an enlarged ovary.

It will probably suggest itself to some of you that, if my explanation is right, it also accounts for the presence of free fluid in the abdominal cavity, and that the disappearance of this fluid is to be attributed to the completion of the process of absorption and not to a successful Talma-Morrison operation. Mr. Haughton's evidence is, however, very clear on this point. Prior to the operation the patient had been tapped some five times, and large quantities of fluid were withdrawn. At the time of operation, the liver was found to be paler in colour than normal, of a fibrous consistence, and slightly reduced in size. Subsequent to operation, she improved with great rapidity, and no further accumulation of fluid occurred.

THE ROLE PLAYED BY THE TONSILS IN ORGANISATIONAL DISEASES.

By STEPHEN J. ROSS, M.D., Ch.B.,
 Surgeon to Out-patients, Bedford County Hospital.

It has often appeared to me that we general practitioners are often apt to overlook the important part played by the tonsils as the points of entrance of organisms in specific diseases.

A child, æt. 14, developed a slight nasal catarrh and tonsillitis. The mother regarded the case as one of "cold," and no further notice was taken of the case, until three weeks afterwards, when weakness of the legs was noticed, I then saw the child, which was suffering from post-diphtheritic paralysis. The knee-jerks were absent.

This points to the absolute necessity of never treating as trivial a case of tonsillitis, however slight. A more instructive case is that of a woman, æt. 49, the subject of heart disease in the form of mitral regurgitation. She developed a tonsillitis. I made cultures from a throat sweep and discovered streptococci and staphylococci, the former largely predominating four days afterwards, when the throat symptoms had subsided and she had a rigor. Her spleen enlarged, and she passed through a typical attack of infective endocarditis. From her blood I cultivated streptococci. Had I not seen the case when suffering from this apparently slight attack of tonsillitis the source of the infection would have remained obscure.

Take again the case of scarlet fever.

I have frequently cultivated streptococci from the tonsils of patients suffering from scarlet fever, also from the nasal discharges and from otitic discharges. Frequently have I attempted cultivation from the scales of a desquamating case and have invariably failed. Is this to be wondered at, as these scales are more or less dead epithelium, the result of hyperæmia, which we see in cases of urticaria, measles, or any other hyperæmic condition? I am convinced that scarlet fever is spread by the tonsils and nasal or ear discharges. There is far more danger in allowing a patient with a discharging ear, to mix with the community at large than a patient who has not quite completed desquamation.

A youth, æt. 16, had a chill, and complained of "sore throat." Forty-eight hours afterwards he had a rigor, temperature 104°. He passed through a sharp attack of pneumonia. Crisis occurred upon the tenth day. Diplococci were present in his sputum. Repeatedly have I seen a very painful form of tonsillitis associated with high fever, which in three or four days' time has been followed by an attack of rheumatic fever. Here, again, the tonsils were clearly the site of entrance of the organisms.

Lately I have had a case of acute pulmonary tuberculosis in a youth, æt. 21. Notwithstanding frequent mouth cleansing he developed a temperature of 106°. I felt sure it was a case of "mixed infection," from mouth sepsis. I made a tonsillar sweep and discovered streptococci, staphylococci, micrococci and bacteria. I determined to try the effect of anti-streptococcic serum. I injected 10 c.c. After the injection he fell into a sound refreshing sleep. His morning temperature was 99°. The following evening his temperature was 101°. It, never rose above this up to the time of death, which occurred ten days after his attack of hyperpyrexia. Many more similar cases could I cite, and I am sure that many of your readers could amplify my notes.

In most cases of infectious diseases tonsillitis forms a prominent symptom. So also it is from the tonsils that we have to fear the spread of infection. Your whole energies must be concentrated upon disinfecting the tonsils by the naso-pharynx. We can leave such problematical causes of the spread of the disease by scales to look after themselves.

I have omitted to refer to the tonsillitis which precedes an attack of influenza. Often the only complaint for twenty-four hours is that of a sore throat, then surely follows the aching of limbs, and too often the tedious recovery with which we are all too well familiar.

THE INTRA-VENOUS INJECTION OF FOR- MIC ALDEHYDE FOR PULMONARY TUBERCULOSIS.*

By F. W. BAKER YOUNG, M.B., CH.B.,
Resident Surgeon to the Hospital for Children and Women, Leeds.

IN this paper the author referred to the lecture delivered by Dr. Robert Maguire before the Harveian Society and published in the medical journals

(* Abstract of paper read before the Liverpool Medical Institution, March 15th., 1906.

during November, 1900, wherein Dr. Maguire's method of injecting hæmasepsin, a solution of formic aldehyde in normal saline, and the strength of the solutions used might be found. The treatment of an advanced case took about six months; at the end of six weeks, if the treatment was going to be of any service, the patient showed a marked improvement both in physical signs and symptoms. The immediate results of injection were (1) pain over the vein, which, if severe, could be relieved by firm pressure; (2) increase of moist sounds in the chest for a short time; (3) suffocative cough of a few seconds duration; (4) taste of formaldehyde; (5) odour of formaldehyde in the breath; (6) rigors, which occurred in every case, but not after every injection, varied considerably in their severity, and were to be treated by hot-water bottles, hot drinks, &c. Formaldehyde could be recognised in the urine and sputum by the following test:—If .05 grms. of resorcin, 5 c.c. of a 50 per cent. solution of carbonate of soda, and 5 c.c. of the solution of formaldehyde were well boiled, a permanent red colour was formed distinguishing formaldehyde from all other aldehydes. This reaction would take place in a dilution of 1 in 10 millions (*Journal of the Chemical Society*). Formaldehyde could be detected in the urine one week after, and in the sputum two days after, an injection of the 1 in 500 solution.

If it were objected that formaldehyde would be rendered inactive by reacting with other substances, he would reply that, since the velocity of any reaction was proportional to the concentration of the reacting substances, and that with injections of the strength of 1 in 500 the dilution would be, in the pulmonary circulation, 1 in 25,000, and in the systemic circulation still greater, reaction with other substances in the blood, if any, must be extremely slow; that very little reaction did actually take place was proved by the appearance of formaldehyde in the urine a week after the injection. Dr. Baker Young then read notes of a case of phthisis of nine years' duration, which he had treated by this method for seven months. The chronic course of the case had been interrupted by three acute attacks marked by high temperatures and hæmorrhages (in 1896, 1900, and the fall of 1904). Injections were begun February 26th, 1905. At that time the physical signs were well marked and bacilli were abundant in the sputum. A steady improvement took place until, in August, no bacilli could be found in the sputum. The injections were continued until October, when examination revealed no signs of active tuberculosis, though a small area of dulness existed where formerly a pleuritic rub could be heard. The urine had never contained albumen, and the Diazo reaction, tried twice towards the end of the illness, was negative. The patient was now sheep-farming in Punta Arenas, and reported himself free from recurrence.

THE annual meeting of the Medical Graduates' College and Polyclinic was held on the 23rd inst. at 22, Chenies Street, Gower Street, Dr. C. Theodore Williams in the chair. The report for 1905, which was read, stated that 1,224 cases of disease, many of extreme rarity and interest, were shown at the clinics, and the attendance of medical practitioners at these clinics and the lectures numbered 14,891 for the year.

CLINICAL RECORDS.

CASE OF ENDOTHELIOMA OF THE UTERUS.*

By MRS. SCHARLIEB, M.D.LOND., M.S.,
Senior Physician for Diseases of Women to the Royal Free Hospital,
London.

Mrs. S., æt. 50, November 3rd, 1905. Nine children, youngest 16. Periods regular to the end of 1904, since then much discharge, which lately has been thick and blood-stained. Three months ago noticed a lump in abdomen. Complains of feeling weak. There is much urgency of micturition, with scalding; the bowels are badly constipated.

On examination a very large, hard tumour was felt in the abdomen; it was markedly irregular and suggested papillomatous growths. On vaginal examination the cervix uteri was irregular, the os uteri partly dilated, there protruded through it a papillomatous mass.

Nov. 10th, 1905.—*Operation*.—The parts removed consisted of the uterus and appendages.

The Pathologist's report was as follows:—"The specimen consists of an enlarged uterus with its appendages, and weighs 31 ozs. The uterus is the size of a 4½ months' pregnancy; it measures after fixation from the fundus to the external os, 6½ inches. The transverse measurement across the widest part of the fundus equals 4½ inches. The antero-posterior diameter at the same level equals 4½ inches. The outer surface of the body of the uterus is smooth and covered with peritoneum. The surface shows a few dilated venules, but is apparently healthy, except over the posterior surface, where it is roughened by the attachment of numerous short, fibrous tags. The growth does not involve the surface at any place in the body of the uterus. The cervix is much enlarged from the internal os to within ½ inch of the external os. The enlargement involves the whole circumference of the cervix. In front it is more marked and forms a rounded swelling covered by a smooth surface, the remnant of the uterine wall. On the left side, the growth has perforated the left wall of the uterus, and forms an irregular mass projecting from the surface into the left broad ligament. The growth has been cut through during the removal of the uterus. The external os is dilated and measures ½-inch across. Several ragged pieces of growth project through it. The anterior lip of the cervix is thickened and invaded with growth, the posterior lip is of normal size.

On Section the uterus is found occupied by a large mass of solid growth filling the body of the uterus and extending downwards, and involving the cervix. The main mass of the growth is attached to the anterior wall of the uterus and measures 3 inches in its antero-posterior direction. There is also a mass of growth involving the anterior wall of the cervix continuous with the former and measuring 1 inch from before backward. The posterior uterine wall is lined by a much thinner, but very irregular layer of growth. The growth is firm and uniformly yellowish white in colour. The cavity of the uterus is 9 inches long, and is situated near the posterior surface. At the upper end it turns forward over the upper surface of the growth. It is lined throughout by growth, the surface of which is very irregular and ragged. On the posterior side the uterine wall it is ½ inch thick; at the fundus it measures ½ inch, at the anterior surface the growth has almost reached the outer aspect of the uterus, and was only separated from it by a thin layer of muscular tissue.

The uterine appendages are healthy.

Microscopical Examination.—Sections were taken from several parts of the body of the uterus and from the cervix. Microscopically the growth is an endothelioma. The sections taken from different parts vary

considerably in appearance. In the most typical places, the growths consist of columns of cells embedded in interstitial tissue. The cells are arranged in the manner of the tumours described by Dr. Lazarus-Barlow as peritheliomata. There is a central cavity containing blood and lined by endothelium. This is bounded by a vascular wall of varying thickness, which is again surrounded by a thick layer of cells of the neoplasm, giving the appearance of a growth composed of a collection of vascular tubes, the outermost walls of which are formed by masses of the cells of the new growth. The cells have a fairly large amount of clear protoplasm. They have round, deeply staining nuclei, in which a nucleolus can usually be made out. The interstitial tissue varies much in amount in different parts of the growth. In places it is large in amount, and consists of well-formed fibrous tissue. In parts also it is very scanty, and the cells of the growth have no very definite arrangement, giving here the appearance of an alveolar sarcoma.

Course.—Wound healed by primary union, and no trouble occurred with the bladder. Mr. Berry examined patient on November 29th, but thought that no removal of rectum was feasible on account of the extent of the growth involving it. He advised colotomy should signs of obstruction supervene.

CASE OF PERITHELIOMA OF THE UTERUS.

Miss W., æt. 44, November 16th, 1905. Three years ago had a flooding when in Edinburgh, for which she was curetted. For the last six months every period has become more profuse, but not painful.

On November 3rd, was suddenly taken ill with a flooding which subsided after a few days, but as soon as she got up moderate hæmorrhage recommenced and persisted. On examination the uterus was not very large, was slightly irregular, the irregularity being apparently due to small fibroids which were best felt per rectum.

The Pathologist's report was:—

"The slide prepared from one of the blocks shows nothing of importance, there is fibro-myxomatous tissue overlaid by a slight amount of hypertrophied mucosa. The second slide is important on account of the changes in the endometrium. The tubules are actively proliferating, and their epithelium in one particular area has burst its basement membrane, and forms irregular masses of malignant looking cells; the latter are seen lying amidst fragments of tubules, the whole presenting a very complex and irregular appearance. It is noteworthy that the uterine muscle is not invaded by gland tissue, either malignant or benign. The above signs of early malignancy apply to a more or less circumscribed area of the mucous membrane. The bulk of the mucosa shows a benign hypertrophy of glands."

THE OUT-PATIENTS' ROOM.

WESTERN OPHTHALMIC HOSPITAL.

Fascicular Keratitis.

By G. W. THOMPSON, M.B., F.R.C.S.

AMONGST the out-patients was a boy, æt. 4, who was suffering from one of the rarer forms of phlyctenular ulcer of the cornea, "so-called Fascicular Keratitis." Mr. Thompson said that this condition generally commenced at the limbus of the cornea as a small, greyish yellow ulcer; this ulcer extends in a radial direction towards the centre of the cornea, and as it extends it heals at the periphery, carrying with it a leash of vessels. This condition may continue until the ulcer has reached the centre of the cornea, and even beyond towards the opposite side. The final condition, when the progressive course of the ulcer has been arrested by natural or therapeutical means, is a narrow, greyish white superficial snail-like track across the cornea, considerably impairing visual acuity when the track has invaded the pupillary area of the cornea, a condition which is very much to be regretted. When an

* Read at meeting of British Gynecological Society, March 8th, 1906.

ulcer of this type has to be dealt with in addition to the usual local treatment, which in his opinion should consist of a simple cleansing lotion and rarely, if ever, atropine (as it only increases the photophobia), the general treatment, which in these cases is of far greater importance than the local, consists of cod liver oil and maltine, and iron and arsenic. The great point is, if within a week or a fortnight the ulcer is seen to be making progress (this can only be judged by always carefully marking the usual corneal chart each visit) to put the child under an anæsthetic, scrape the ulcer, and carefully apply two drops of pure carbolic acid, taking care, by the use of a small piece of blotting paper, that the acid does not touch healthy tissues. By these means the progress of the ulcer is certainly arrested and a permanent scar, which is so often seen encroaching on the pupillary area of the cornea, is avoided. A fairly recent drug, dianine, in a 3 to 5 per cent. solution, frequently instilled, Mr. Thompson pointed out, often relieves photophobia and blepharospasm. If atropine is employed it rarely ought to be used more than two or three days.

The treatment mentioned was carried out on this patient; the local application of dianine, &c., and the general treatment having proved inefficient to entirely arrest the progress of the ulcer within seven days, the ulcer was scraped and touched with carbolic acid. This proved quite effectual, the ulcer healing rapidly, leaving only a very small scar in the outer third of the cornea which will not in any way impair vision.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

INGUINAL COLOSTOMY.—Mr. T. P. LEGG operated on a woman, æt. about 50, who had been admitted for chronic constipation; she stated she had had increasing difficulty in getting the bowels to act for several months, and had been in the habit of taking purgatives regularly; these now had ceased to be effective. She had not vomited, and there had been no discharge of blood or mucus per anum. During the last few weeks she had had an intermittent colicky pain most marked on the left side of the abdomen. She did not think she had lost much flesh. On examination, the abdomen was distended, especially in the left iliac and lumbar regions; the amount of distension varied, and from time to time the peristaltic wave was readily observed to pass from above downwards in these regions. During this time, the distension increased, and the patient suffered from the colicky pains above mentioned. On palpation the sigmoid was easily felt to be distended and thickened. On making a rectal examination, a hard nodular fixed mass was felt high up on the left side of Douglas's pouch. There was nothing else abnormal to be detected, the right side of Douglas's pouch being quite normal. A diagnosis of malignant disease of the sigmoid flexure was made. An incision as for left inguinal colotomy was made; the hypertrophied sigmoid presented in the wound and was at once drawn out so as to expose the growth; this was found to be situated in the lower part of this portion of the gut, to involve about an inch and a half of its length, and to have produced a very tight stricture as if a piece of string had been tied round the intestine, there being a distinct furrow visible on the peritoneal aspect. At one part a coil of small intestine had become adherent to the growth, and in the wall of this piece of small bowel a nodule of growth the size of a small nut was found directly continuous with that in the sigmoid. The upper part of the sigmoid was fixed to the margin of the incision in such a way that a U-shaped loop of bowel projected on the surface; this loop was fixed to the margin of the incision by three

stitches, a middle one transfixing the meso-sigmoid, and the two edges of the incision; the upper and lower limbs of the loop were fastened to the incision by stitches passed through the muscular and peritoneal coats of the bowel, and the whole thickness of the parietes. This completed the first stage of the operation, the bowel not being opened as there were no urgent symptoms. Mr. Legg said this was a fairly typical case of its kind, namely, of carcinoma of the upper part of the sigmoid flexure. This form of carcinoma was comparatively mild in its malignancy, and not infrequently the patient comes under observation when obstruction, very often complete, has set in, but a careful inquiry into the previous history will generally elicit such symptoms as those this patient complained of. In all these cases of chronic constipation occurring in people advancing in years a rectal examination should never be omitted, and this was specially important on account of the absence of rectal symptoms. The present case, he thought, was a good example of the treatment to be adopted in the first instance, namely, a colotomy which should always be done to relieve the obstruction, and if the local conditions are favourable for removal of the growth this latter can be undertaken two or three weeks later. Excision of the growth should never be done whilst the patient is suffering from obstruction. If removal can be carried out, the prognosis is very good. In this particular instance removal would not be undertaken, first, because intestinal obstruction was present, and, secondly, because a double resection of the intestine would have been necessary on account of the involvement of the small intestine, and Mr. Legg did not think that the growth in the small intestine would give rise to any severe symptoms. As to the method of doing the colostomy, the most essential point, he thought, was to obtain a good spur, which was accomplished by placing a large U-shaped loop of intestine in the wound as he had done. When the projecting portion of bowel was removed, the upper opening would be entirely separated from the lower opening by the intervening portion of meso-sigmoid, and this first opening would be completely surrounded by the muscular coats of the bowel, the circular muscle developing into a sort of sphincter. The patient very often gains some amount of control, the bowels acting only twice or thrice in the twenty-four hours. It was considered unnecessary to open the bowel at the time of operation because the abdomen was not generally distended, and the patient was not vomiting; in the absence of either or both of these symptoms the bowel, he remarked, would not be opened for four or five days; during this time adhesions would have formed between the intestine and the wound, thus shutting off the general peritoneal cavity. It was, he considered, best to make only a small opening at first and to tie a Paul's tube into the lumen, the contents of the bowel being thus carried away into a receptacle at the side of the bed and risk of infection would be diminished. At the end of a week or ten days the whole of the projecting loop would be removed. There was one other point, Mr. Legg said, to be considered in the after treatment of these cases; in the piece of intestine in which the growth is situated a certain amount of intestinal mucus and secretion accumulates above and below the disease, and if this is allowed to go on accumulating it causes considerable discomfort. This can be entirely obviated by regularly irrigating this part of the bowel from the lower opening of the colotomy wound and from the anus.

The patient made a satisfactory recovery; the bowel was opened on the fifth day and she left the hospital at the end of the month.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, MARCH 23RD, 1906,
MR. CLINTON DENT in the Chair.

REMOVAL OF MEDIASTINAL SARCOMA BY THE X-RAYS.

DR. J. T. ZUM BUSCH showed a mediastinal sarcoma which disappeared after treatment by the Röntgen rays. The patient, a man *æt.* 37, suffered from syphilis in 1896 and had been almost continually under mercurial treatment for years. Altogether he used 4800 grms. of grey ointment for inunction, and took a large number of mercurial pills; he also had thirty-five intra-muscular injections of hydrarg. salicyl. In spite of this vigorous treatment psoriasis palmaris recurred in September, 1904, when he came under my treatment. The patient at that time was very anæmic and looked ill; his breath was very short. The face and neck were very swollen and cyanosed; the superficial veins of the whole body, and especially the right epigastric veins, were enormously enlarged. He complained of pains in the right half of the thorax, which had for the first time occurred about four years ago. The pains came in attacks, always at night-time, and lasted for two or three hours. At first the intervals between the attacks had been very long; gradually, however, they had become shorter and shorter. Two years ago he began to complain of giddiness and pain in the left half of the head and pressure in the left eye. About this time the veins commenced to swell; the swallowing became difficult. During the winter 1903-1904 the condition became worse; the attacks occurred almost every night. The spring and early summer brought a slight improvement. In August, 1905, he had a very severe attack of pain, which lasted five hours and left a swelling in the region of the second and third sternocostal joints. The swelling increased in size and became painful. About four weeks later a large lump was noticed in the right supra-clavicular space. There were frequent rises of temperature and patient lost weight rapidly. When seen in September, 1904, his condition was as above described; there was a large mediastinal tumour, which pushed the second and third rib on the right side of the sternum forward; this tumour could easily be made out by percussion, and was seen by examination with the Röntgen rays. The breathing was very short and the swallowing difficult; distinct sound could be heard when the patient tried to force some food down. There were some hard, irregular glands to be felt above the clavicle, and a deep resistance on pressure over the jugulum. An examination of the blood gave a normal count. The present state seemed to warrant the diagnosis of a malignant tumour of the mediastinum. In view, however, of the co-existence of a typical syphilitic eruption, and of the nocturnal attacks of pain, the possibility of a large gumma was thought of and the patient treated accordingly by intra-muscular injections of hydrarg. salicyl. and by the internal administration of 1.0 gm. potassium iodide three times daily. The skin eruption disappeared rapidly; the tumour, however, remained quite stationary. In January, 1905, the patient caught a slight cold, which was followed by an unusually severe attack of pain, by coughing, hoarseness, still greater difficulty in swallowing, and paræsthesia over the left half of the body. The pulse rose to 120 and has remained more frequent since that time. At the beginning of the Röntgen ray treatment (February 10th) the condition was as follows: Area of dullness extending to both sides of manubrium sterni (more to the right) 14.5 cm. broad; at the level of the third rib it is only 11 cm. broad. Second and third costal cartilages on the right side very prominent. Hard,

irregular glands in supra-clavicular space on right side. Veins greatly dilated. Pupils of equal widths and normal reaction. Heart sounds normal. pulse frequent. The blood count was normal. The skiagraphic examination confirmed the diagnosis of a large mediastinal tumour. A gelatine capsule filled with bismuth, which the patient tried to swallow during the examination, did not pass further than to the level of the jugulum, where it stuck. In view of the syphilitic history an inunction treatment (2.0 *per diem*) was begun, and the tumour was exposed to the Röntgen rays in the following way: From February 11th to 18th the prominent part of the tumour was treated daily from five to six minutes. After the first two sittings the patient felt greatly improved; the pain had disappeared and the difficulties in breathing and swallowing were much less. After the sixth sitting the prominence had disappeared. From February 10th to 25th the intra-scapular space was treated in the same way. From February 27th to March 2nd the lateral parts of the thorax were treated. From March 18th to 28th and again from April 2nd to 14th the anterior wall of the thorax was exposed. The patient came back to London and was seen on April 20th. His condition was greatly improved; the dullness over the sternum was only 8.5 cm. broad, the prominence of the ribs and the enlarged glands had entirely disappeared, the veins were normal in size. The patient had gained 3 klg. in weight, slept well, was entirely free from pain, and had no difficulty in breathing or swallowing. On May 10th he again came to be seen, and complained of some giddiness. It was found that the glands in the supra-clavicular space had become again enlarged and hard. As one of the glands felt fairly movable, it was removed for diagnostic purposes. The gland was slightly adherent to its surroundings, looked homogeneous and glassy on section, and showed no trace of caseation. Microscopically it proved to be a sarcoma, which showed in some parts an alveolar structure. The patient was advised to return to Vienna for further treatment. He had five further exposures between May 22nd and 26th, after which the glands had almost disappeared. Since that time the patient had remained in very good health; he is quite able to do all his work as an engineer, he has gained in weight, and is quite free from pain.

A very similar case has been published by A. Cloppatt in the *Deut. Med. Woch.*, No. 29, 1905.

MR. LUNN asked whether there were any sections to be seen of any secondary deposit.

MR. W. G. SPENCER thought that the difficulty lay in distinguishing between sarcoma and lymphadenoma. Undoubtedly many cases that would be termed the latter in England were called sarcomatous in Germany. He referred to the danger of treating operable cases of malignant disease with the X-rays.

DR. ZUM BUSCH showed sections of the gland.

DR. H. G. TURNEY showed a case of bony tumour of skull. The patient was a man, *æt.* 42. He had noticed the swelling on the top of his head for seven or eight years. For the last eighteen months he had had headache, which is getting more severe. The headache was worse during the day; in fact, he slept well at night. He had had three "fits," at intervals of about two years, during the last six years, and four or five years ago he had right-sided facial paralysis of infra-nuclear type. *On examination.*—A large smooth bony growth occupying the right and anterior portion of the calvarium and extending across the mid-line for some distance. No optic neuritis; no signs of nerve involvement. No vomiting nor slowness of pulse. The tumour was probably a simple osteoma.

Dr. BERTRAM ABRAHAMS showed a case of sudden paralysis of the third cranial nerve. The patient was a married woman, *æt.* 47. Exhibited at the last clinical evening of the Society, January 26th. Paralysis of the left nerve was then total. It was suspected that the lesion was of specific origin. She was accordingly treated with potassium iodide for between two and three weeks without the slightest obvious effect. She was then put, instead, upon mercurial inunctions, and soon began to show improvement, which is now steadily progressing. The original attack occurred suddenly on January 20th. Visible improvement had begun by the middle of February, and by the middle of March the ptosis had virtually disappeared. *Present condition of left eye.*—Ptosis very slight. Pupil moderately dilated; inactive to light and accommodation; backward deviation has decreased. There is some recovery of action of internal and inferior recti, less of superior rectus. The diplopia is now as follows: Crossed diplopia to right of mid-line, with increasing separation of images with movement to right. Diplopia above level of centre of eyeball, with false image below line, and distance between images increasing with movement upward. No diplopia below level of centre of eyeball.

Dr. BERTRAM ABRAHAMS showed a case of adipositas dolorosa. The patient was a married woman, *æt.* 40. Rheumatic fever at 20; in hospital three months. No menstrual disturbance. Two sisters and one daughter stout; remainder of family slight. No history of syphilis. Patient was slight until her last child was born, three years ago. Since then has become steadily stouter and has had constant aching pain in the lower part of the back on left side. As the stoutness progressed tender places have gradually developed about the body. She is clothed universally with a thick adipose layer. Over certain areas—(1) back of right arm, (2) outer aspect of right arm just below shoulder, (3) outer aspect of left forearm, (4) right hypochondriac region, (5) inner aspect of left thigh just above knee. The patient complains of tenderness, and some additional thickening of the subcutaneous tissues can be felt. On the outer side of the left leg there is tenderness, but no such thickening can be felt: here there are varicose veins. There is no disturbance of sensation. Heart sounds distant and feeble. Thyroid natural; mental activity good; skin healthy.

Dr. TURNER recalled a similar case in which the pain appeared only late.

Dr. JOHN J. DOUGLAS showed a case of dislocation of the metatarsus. The patient, a man *æt.* 24, was thrown from a cart on January 19th, 1906, the wheel going over his right foot. When first seen the foot was much swollen, but there was no very striking deformity. As the swelling subsided, the internal cuneiform bone was seen to be unduly prominent. On February 6th, a skiagram showed the whole metatarsus dislocated outwards, the first metatarsal being in apposition to the middle cuneiform and the fifth almost off the cuboid. Reduction under the anæsthetic was attempted, but failed, on February 8th. On February 12th an incision was made along the inner margin of the foot, and the joint between the first metatarsal and internal cuneiform exposed. It was then found that the portion of the tibialis anticus internal tendon inserted into the base of the first metatarsal had got between that bone and the internal cuneiform, and was seemingly the obstacle to reduction. This being pulled out and replaced, the metatarsus was pushed into position with comparative ease.

Mr. NITCH described a similar case he had seen under Mr. Clutton's care, and showed a cast of the foot.

Mr. W. B. SPENCER showed a case four years after fixation of omentum for ascites. The patient was a woman, *æt.* 54. In hospital four years ago with alcoholic hypertrophic cirrhosis and ascites; pigmentation of legs; no other signs of syphilis. Tapped

and refilled, drained and refilled, drained and omentum fixed in epigastrium. Liver found enlarged, nodular. Has continued to take alcohol as before, but no fluid has collected since. No œdema. No albuminuria. Re-admitted for complete removal of fungating cancer of left breast, including pectoral and axillary glands. Right supra-clavicular gland enlarged. Liver felt as much below ribs as at first.

Dr. STONE described an autopsy he had carried out on a successful case of this operation.

Mr. J. G. GIBB showed a sporadic case of Friedreich's disease. Boy, *æt.* 13, school standard II. No history of any nervous or mental disorder in the family. Father and mother healthy, but are first cousins; one sister strong and well, *æt.* 14. Nothing unusual noticed till he was five years old. Then in walking up hill and after walking rather far he complained of pain in the small of the back; in walking he rolled from one side of the path to the other. He is bright and intelligent, although the expression is a little vacant. Muscular development is poor. He stands with a forward inclination of the trunk, neck bent to the right, arms forward, hands supinated, and feet apart. There is some static ataxia. His walk is swaying, staggering and irregular. There is a slight stamping, but rather of the ball of the foot than the heel. He turns with difficulty. Speech is slow, and sometimes blurred. The spine shows slight curvature, with convexity to the right in the mid-dorsal and to the left in the lower cervical regions. There is pes cavus when feet are off the ground. Romberg's sign with tendon movement is marked. Knee, ankle, supinator and biceps jerks are absent. There is some inco-ordination of the upper extremities and slight lateral nystagmus, more to right than to the left. Sensory functions are not disturbed.

Mr. W. G. SPENCER recalled a case of Friedreich's disease due to parental consanguinity.

Dr. ARTHUR VOELCKER showed a case of splenomedullary leukæmia (myelæmia) in a boy. The patient, a boy, *æt.* 10½, had been admitted to the Hospital for Sick Children. *Present illness.*—Patient was quite well till four months ago, when he began to lose weight and became pale. The abdomen had been enlarging for two months. No abdominal pain. Several attacks of epistaxis lately. *Previous history.*—Unimportant. *Present state.*—Rather pale, but lips and beds of nails of very fair colour. Spleen very large, extends down to pelvis. Liver extends ¼ inch below costal margin. Glands in groins and axilla slightly enlarged. No tenderness about the bones. Urine contains a trace of albumen. Soft hæmic murmur at pulmonary cartilage. No retinal hæmorrhages. *Blood.*—Report by Dr. J. Graham Forbes. Hæmoglobin, 70 per cent.; colour index, 1.06; erythrocytes, 3,302,000 per c.m.m.; leucocytes, 400,000 per c.m.m. *Differential count.*—Polymorphonuclear, 36.8; large mononuclear, 3.6; small lymphocytes, 9.6; large lymphocytes, 8.4; eosinophiles, 7.6; basophiles, 13.6; myelocytes, [(1) finely granular eosinophilic, 14; (2) coarsely granular eosinophilic, 6; (3) basophilic, 0.4 = 20.4].

Dr. ARTHUR VOELCKER showed a case of functional hemiplegia in a boy. The patient, a boy *æt.* 9 yrs. 8 mos., two and a half years ago suddenly lost power in his legs. He was admitted as an in-patient at Great Ormond Street, where it was noted that he could not sit up; he had very little power in his legs, less in the right than in the left. Slight tremor in the upper limbs. Some nystagmus on extreme outward movement of the eyes. Knee-jerks exaggerated. Ankle clonus present on both sides. Plantar reflex extensor on both sides. Occasional incontinence of urine. A provisional diagnosis of disseminated sclerosis was made. The boy contracted scarlet fever, was sent to the Fever Hospital, from which he returned quite well, and has continued so till March 9th, 1906. Present illness began suddenly, with weakness of the left arm and leg. He could not sit up when brought up to the hospital; there was left hemiplegia. Face not affected. The

forearm muscles were most affected. Grip very weak on left side. Knee-jerks exaggerated. No ankle clonus. Extensor reflex on both sides, but next day on left side only. Sensation natural. Lateral nystagmus on looking to the right. Speech natural. No optic neuritis or atrophy. No incontinence of urine.

Mr. T. H. OPENSHAW showed a case of congenital absence of the fibula and malformation of the head of the femur (congenital coxa vara) simulating congenital dislocation of the hip. The patient was a girl, *æt.* 6. Mother and father healthy; no deformity in the family; seven other children, all perfectly formed. Liquor amnii abundant; good time when carrying; no fright or injury; natural birth; normal labour; vertex presentation. Child walked first when two years old. Now walks very well, but drops down on to the left foot. Right leg, 19½ ins.; left leg, 13½ ins. The left foot is valgus at the ankle. The internal malleolus is prominent. The tibia presents at the middle of the shaft a slight linear dimpling, situated exactly over and parallel with the anterior border of the tibia. The fibula is absent, except for a small portion at the lower end an inch to an inch and a half in length. The left knee-joint is normal, except that the internal condyle is a little prolonged. The patella is present and in normal position. The left femur is much shortened; it measures 6½ ins. from the great trochanter to the external condyle, the right femur measuring 10½ ins. There is marked thickening of the bone at the great trochanter. The whole lower extremity is rotated out through an angle of 35°, but there is no flexion, adduction, or abduction contraction at the hip-joint. Of the movements, reflexion is a little limited; abduction is only possible through a range of 10°; adduction is increased, the left knee crossing the upper third of the opposite femur in full adduction; rotation out is increased 20°, and rotation in is normal as compared with the right leg. When the leg is fully adducted the great trochanter and what appears to be the head of the bone are distinctly felt beneath the glutei muscles. The X-ray, however, shows the head of the femur situated in the acetabular cavity. The acetabulum appears to be well formed. The upper end of the femur consists of no less than seven pieces. The head of the bone is normal in shape, but is small. The neck of the femur is in a position of acute coxa vara, and is represented by two pieces of bone, as if there had been a fracture of the neck. On the under surface of the neck there is a thin plate of bone, and on the top of what is in all probability the great trochanter there are two other fragments. The X-ray showed a faint trace of ossification in the lower end of the fibula. The child stands with the right knee flexed almost to a right angle. There is drooping of the pelvis on the left side, and a little lordosis and left convex lateral curvature.

Mr. T. H. OPENSHAW showed a case of double coxa vara (rickety). The patient was a boy, *æt.* 12. There is no family history of any similar condition—no history of accident or injury. As a child, the legs were rotated out and abducted. Marked genu varum and curved tibiae were noticed at the age of eighteen months, with enlarged wrists and fontanelles late in closing. Except the coxa vara, there is no evidence of rickets at the present time. Lordosis was first noticed about the age of five years. *Present condition.*—There is extreme lordosis. The great trochanters are elevated and prominent. The legs are equal in length. The legs are markedly adducted and cannot be abducted. The right leg measures 28 ins. The upper border of the great trochanter is on the same level as the anterior superior spine. Flexion is only possible 40°. The leg is adducted to an angle of 45°, abduction impossible, rotation out through an angle of 25° and rotation in for 10° only. There is flexion of the right knee and valgus of the right ankle. The left leg measures 28 ins. The upper border of the great trochanter is slightly above the level of the anterior superior spine. Flexion only to an angle of 90° is possible, adduction to 45°, abduction impossible. Rotation out through an angle

of 25°. The thigh cannot be rotated in beyond the position in which the patella looks directly forward. The left knee is in a position of varus, with prominence of the head of the fibula, and the left ankle of valgus. An X-ray picture of the femur on each side showed the head of the bone situated in the acetabulum, and well formed. The upper edge would appear to be an inch and a half below the upper border of the great trochanter. The neck of the femur seems altogether wanting. There is a flattened surface at the root of the head which would appear to rest against the inner surface of the great trochanter. The upper border of the great trochanter is prolonged upwards and inwards, and impinges against the outer surface of the ileum, even when the femur is perpendicular, thus rendering abduction impossible. The angle made between the shaft of the femur and a line passing up long the upper border of the head and neck would appear to be about 60°, and is equal on the two sides. Another X-ray picture was exhibited, which was taken three years ago. In this condition the head of the bone is not nearly so much depressed, being only half an inch below the top of the great trochanter on either side, and there would appear to be a short thick neck to the femur. The angle made by the neck with the centre of the shaft of the femur would appear to have been 82° three years ago. The boy walks with extreme waddling gait, the lumbar vertebral column being flexed laterally with each step.

Mr. T. H. OPENSHAW showed a case of left traumatic coxa vara due to an extra-capsular fracture of the neck of the femur. The patient was a boy, *æt.* 12. On Christmas night he slipped on a stone and fell upon the great trochanter. He felt acute pain and was unable to stand. He was carried home and stayed in bed more or less for a fortnight. He then limped about for a week and came up to the hospital, where he was radiographed. The X-ray showed a fracture of the femur, so he was admitted into the London Hospital, under my care, on January 15th, 1906. On admission the left leg was shortened one inch, and the left great trochanter was half an inch above Nelaton's line. Bryant's triangle was half an inch shorter than on the other side. There was some thickening about the great trochanter, but there was no evidence of old bruising. From January 15th to March 7th, a splint was applied to the leg adducted at an angle of 45°. Since March 7th the leg has been in plaster-of-Paris. The X-ray showed a fracture at the outer extremity of the neck of the femur. There appears to have been no marked impaction. The upper edge of the head is level with the top of the great trochanter, and the angle formed by the neck with the shaft of the femur is 95°. The head of the bone is well shaped and normal as regards its epiphysial surface.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD MARCH 7TH, 1906.

Dr. J. O. AFFLECK, President, in the Chair.

DR. MACKENZIE showed a case suggestive of General Paralysis. The patient was a lad, *æt.* 19, who had always been somewhat backward, and only walked when *æt.* 5. He was the seventh of eleven children, and in none of his brothers or sisters, nor in his parents, was there any evidence of syphilis. As a boy of eight or ten, he had "fainting attacks," which were followed by increased mental impairment, and which suggested congestive injuries. For the last few months he had deteriorated mentally so much that he was unfit to perform his usual work as an errand boy. Memory was much impaired, but there were fairly well-marked grandiose delusions. Physically, the pupils were unequal, the speech slurred, Romberg's symptom was slightly present, and the muscular power was poor. The case was probably one of juvenile general paralysis.

Dr. EDWIN BRAMWELL showed (1) two cases of

Hemiplegia due to intra-cranial lesion, and (2) a case of Syringomyelia, which had come under observation on account of a painless whitlow with necrosis of the terminal phalanx. On examination evidences of similar occurrences previously were found in the shape of scars from burns, &c. The position of the hands was characteristic, and there was dissociated anæsthesia over the arms and part of the trunk. In addition, there was an arthropathy of the left shoulder, the joint being disorganised, much swollen, and causing loud grating on movement.

Dr. R. A. LUNDIE read a paper on

TRANSITORY BLINDNESS DUE TO SPASM OF THE RETINAL ARTERY.

Although such cases were in all probability not very rare, only a few had been reported in which the fundus had been examined ophthalmoscopically during an attack. His patient was a man, æt. 88, in whom the circulation was extremely feeble, and the arteries atheromatous. One evening he noticed that his sight had become defective, and then discovered that the vision of one eye was completely lost. Dr. Lundie saw him within half an hour of the onset of the symptoms, and already by that time vision had to some extent been regained in the upper half of the visual field. On ophthalmoscopic examination, the fundus and vessels were normal except the upper main branch of the retinal artery, the course of which was interrupted for a distance equal to a little more than half the diameter of the optic disc. While examining the vessel a fine thread of blood was seen gradually to appear in the portion of the artery which was previously empty. Within an hour of the first symptoms the vessel had returned to the normal size and complete vision was regained. The only feasible explanation was that a localized spasm of the artery had occurred. No thrombus or embolism could have disappeared so suddenly and completely. There had been no recurrence of the blindness. Dr. Lundie also described another case occurring in a lady, æt. 22, who had had numerous transient attacks of amblyopia. After one of these a contraction of the visual field remained, the corresponding part of the retina being œdematous, while on examination some years later a branch of the retinal artery was much contracted. From the transient nature of most of the attacks, it was inferred that vascular spasm was the cause; the spasm, however, had once lasted so long as to permanently impair the function of the retina. Each attack was preceded by vertical diplopia, also transient, and probably due to associated spasm of the artery supplying the extrinsic ocular muscles. There were not many records of cases showing this condition. The only other case (except that described by Raynaud) in which there was a localised transient arterial spasm verified by the ophthalmoscope, was one described by Benson in 1894. During each of three attacks of blindness the branch of the retinal artery corresponding with the insensitive area of the retina was found, as in Dr. Lundie's case, to be empty of blood. In Benson's case the small empty portion of the artery passed along by a sort of peristaltic movement and suddenly refilled. The importance of these cases was the light they threw on what was commonly called "embolism of the central artery of the retina." Probably many such cases were due to spasm, and if this were relieved, as by amyl nitrite or some other vaso dilator, before permanent injury was done to the retina, sight might be completely restored.

Drs. Sym, Ritchie, Church, and Affleck briefly discussed the communication.

Drs. H. M. GRAY and G. M. DUNCAN (Aberdeen) read a paper on

VACCINE TREATMENT IN SURGERY.

The communication consisted of a detailed account of the results obtained from the use of tuberculin (T. R.) as an adjunct to the operative treatment of various forms of tubercle—glands, bones, tendon sheaths, joints, &c. The observers found that it was

necessary to estimate the opsonic index of each individual case in order to determine the exact period of the negative phase. It was sufficient to administer the injections at intervals of ten days or a fortnight. Dr. Gray had also used streptococcal and staphylococcal vaccine with great benefit as a prophylactic against sepsis, particularly in cancerous affections of the mouth as a preliminary to extensive operations, which were otherwise so liable to be followed by pneumonia. The cases described by Dr. Gray were of a highly encouraging nature, and he strongly advocated a more extensive trial of T. R. and similar vaccines as an adjuvant to operative measures.

Mr. STILES was less sanguine than Dr. Gray as to the value of tuberculin; experience had taught him never to be surprised at what Nature could do in the way of curing extensive tubercle, and he recalled cases dismissed from his wards in the Sick Children's Hospital as hopeless which, after a year or two, had returned to hospital again practically healed so far as active disease went. He deprecated any treatment which tended to postpone operation from a favourable to an unfavourable period in the case.

Dr. LAWSON doubted whether clinical symptoms could be relied on to indicate the correct dosage of T. R. The negative phase was of very variable duration and could only be determined by accurate laboratory work.

Dr. J. F. DUNLOP read a paper on

OCCUPATION MORTALITIES IN SCOTLAND.

Having explained the statistical methods employed, Dr. Dunlop divided occupations into six classes, according to whether the death-rates in the two periods—25 to 45, and 45 to 65—exceeded, equalled, or were less than the corresponding death-rates of all males. Class I., low death-rate in both periods includes clergymen, farmers, graziers, agricultural labourers and farm servants. Class II., low death-rate in one period, approximately equal death-rate in the other. Class III., approximately equal death-rate in both periods. Doctors and dentists were among the occupations included in this class. Class IV., high death-rate in one period, low in the other. Class V., high death-rate in one period, approximately equal in the other. Class VI., high death-rate in both age periods, includes coachmen, chemists, tailors, masons, boilermakers, labourers, hotel keepers, publicans, &c. The paper was based on a recent study of the occupation mortalities in Scotland published in the decennial supplement to the forty-eighth detailed Annual Report of the Registrar-General for Scotland.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, MARCH 2ND, 1906.

Dr. FINNY in the Chair.

CIRRHOSIS OF THE LIVER.

Dr. DRURY, with Dr. TAYLOR, brought forward a case of the above, in which operation was performed for the relief of ascites. Patient developed acute ascites, apparently within a week, with great œdema of the legs and suppression of urine to three ounces. The abdomen was tapped, but no great increase of secretion of urine resulted, and it began rapidly to diminish as the ascites again collected. Talma-Morrison operation was then done; patient made a good recovery, and now is daily at work.

ANÆMIA SPLENICA INFANTUM.

Dr. T. GILLMAN MOORHEAD read a paper on the above subject and exhibited the organs from a case of the disease. The patient was a child, æt. 3, with a good family history, who had developed symptoms of anæmia, with abdominal distension, after an attack of measles a year previously. On admission to hospital the spleen was found to be enormously enlarged, extending down as far as Poupart's ligament, and

forward as far as the umbilicus. There were slight rickety signs, and the blood was in every way typical of von Jaksch's disease, except that there was no increase of white cells. Normoblasts were very abundant, and there was marked polychromatophilia. Iron, arsenic, and bone marrow were given at first, and the child was carefully dieted, but without any signs of improvement taking place. Later X-ray treatment was adopted, the rays being directed upon the spleen, but without any apparent effect, and the child died six weeks after coming under observation. At the autopsy the spleen was found to be extremely fibrosed; the liver showed slight fatty degeneration; most of the abdominal and thoracic lymph glands were enlarged, and light red in appearance, and showed fibrosis, plus congestion; the bone-marrow of both femur and tibia was normal, and there was no alteration in the thymus gland or other viscera.

Drs. Langford Symes, Travers Smith, and Peacocke discussed the case. The latter mentioned a similar case under his care which had got well.

UNRESOLVED PNEUMONIA TREATED BY PNEUMOCOCCUS VACCINE.

Dr. J. B. COLEMAN, C.M.G., read the notes of a case of unresolved pneumonia in which the inoculation of pneumococcus vaccine, according to Professor Wright's method, was followed by a satisfactory result. The patient, a labourer, æt. 50, was admitted to the Whitworth Hospital, on December 20th, 1905, suffering from a very severe attack of acute croupous pneumonia, the onset of which had occurred six days previously. On admission to hospital he was in a low typhoid state, his pulse ranging from 126 to 138; respirations, 44 to 48; and temperature, 102.6°. There was consolidation of upper and middle lobes of right lung. On December 23rd, the consolidation had involved the lower lobe of the right lung, and on December 26th, the lower lobe of the left lung was similarly affected. There was no critical fall of temperature, and though the patient's condition somewhat improved, convalescence was very slow. On January 4th, a painful inflammatory swelling developed in the left supraclavicular region; this subsided in three or four days. On January 20th, there was dulness and tubular breathing over the entire right lung, with, in addition, crepitus over the lower lobe; the left lower lobe was dull on percussion. At this date, thirty-seven days after the onset of the disease, the patient's general condition was very unsatisfactory, and there was no sign of resolution in the lungs.

On January 21st, the pneumococcus opsonic index was .60, and on 23rd it was .62, whilst the tubercle opsonic index was 1.

On January 24th, he was inoculated with 46½ millions pneumococci.

On January 25th pneumococcus opsonic index was .69. The inoculation was followed by no local nor constitutional disturbance. Physical signs in patient's lungs were such as might be present in pneumonia of five or six days' standing.

January 30th.—Pneumococcus opsonic index 1.17.

January 31st.—Patient looks and feels better. There is marked improvement in physical signs in both lungs.

February 3rd.—Pneumococcus opsonic index .89.

February 6th.—Pneumococcus opsonic index .91.

February 8th.—Left lung has cleared up. The only physical signs in right lung are dulness and tubular breathing at the apex, and diminished resonance over lower lobe.

February 9th.—46½ millions pneumococci injected.

February 12th.—Pneumococcus opsonic index 1.13.

February 20th.—Patient is in excellent health. He has increased in weight 8½ lbs. since February 1st. Physical signs in lungs as on February 8th.

February 22nd.—Pneumococcus opsonic index 1.09.

February 23rd.—Pneumococcus opsonic index 1.06.

March 2nd.—Pneumococcus opsonic index 1.07.

Dr. Coleman remarked that this was only a single case, and that it would not be fair to deduce too much from it; but the facts pointed to the favourable

result being due to the injection of pneumococcus vaccine administered by Professor Wright's method. In conclusion, he expressed his great indebtedness to Professor A. C. O'Sullivan for having made and supplied him with the pneumococcus vaccine used.

The CHAIRMAN expressed confidence in Dr. Wright's inoculation treatment.

Sir JOHN MOORE deprecated the treatment of pneumonic fever by antipyretics. He believed high fever, if not of too long duration, was followed by rapid resolution.

Drs. O'Carroll, Travers Smith, Moorhead and Stokes also discussed the case, and Dr. Coleman replied.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD MARCH 8TH, 1906.

MR. BOWREMAN JESSETT, President, in the Chair.

DR. JELLETT showed specimens (1) Advanced carcinoma of both ovaries, and (2) Double pyosalpinx, associated with the presence of a four months' extra-uterine foetus, which, with illustrations and the discussion thereon, appeared in our last issue.

Mrs. SCHARLIEB (M.D. Lond., M.S.) read notes of two cases (1) Endothelioma of the uterus; (2) Perithelioma of the uterus, which will be found on page 335 of present issue under the heading "Clinical Records."

In reply to Dr. Heywood Smith, Mrs. SCHARLIEB said that in the second case the uterus was removed by the abdominal route.

DR. SLIMON asked whether in such cases, Mrs Scharlieb had found phenol stop the hæmorrhage?

The PRESIDENT inquired whether the growth had been examined microscopically previous to operation?

DR. MACNAUGHTON-JONES remarked that early removal of the uterus when malignancy was determined by curettage or otherwise was the only course to adopt. Mrs. Scharlieb was to be congratulated on the most interesting and rare case of endothelioma of the uterus which she had brought before the Society. Mr. Maunsell, of Dublin, had shown a similar specimen last session. This disease had only been described of recent years so far as the uterus was concerned, though for the last twelve years or more it has been observed in the ovary.

The PRESIDENT said he thought it was very doubtful how far they could depend on examination of the tissues removed by the curette. On one occasion he submitted tissue removed in this way to a pathologist, who pronounced it to be non-malignant, but the subsequent history proved the case to be malignant, and he had to remove the uterus later. Another case was recorded which was stated to be malignant, but it turned out to be innocent. The President went on to say that in the case of perithelioma he would certainly have removed the uterus by the vaginal and not by the abdominal route. It would have come out very easily by the vagina.

Mrs. SCHARLIEB, in reply, said she had used carbolic acid for cases in which there was considerable hæmorrhage, but in which there was no distinct evidence of malignancy, and had found it useful. But in a case like that shown, where the uterus was certainly malignant, she was very glad it had been removed. The uterus could have been removed by the vagina, but she felt uneasy lest there should be some deposits in the broad ligament, and therefore she thought it best to get as wide a field as possible for the operation. There was no glandular affection in this case.

DR. JELLETT then read

NOTES ON TWO RARE CONDITIONS MET WITH IN THE PELVIS DURING OPERATION.

This paper will be found fully reported and illustrated on page 331.

The PRESIDENT stated that it was laid down by the late Lawson Tait that if a tumour in the abdomen was accompanied by ascites, it was certain to be malignant. There had often been cases of malignant

tumour where the abdomen had been opened and then closed again as the operator was unable to remove the growth, but where subsequently the tumour had ruptured. Possibly that might have happened in the case brought before them.

Dr. MACNAUGHTON-JONES said that the only case he remembered which resembled the one brought before them by Dr. Jellett was a case of ovarian tumour, where, after removal of the cyst, he found a long diverticulum of the colon extremely low down. About one and a half years ago he showed a fibroma of the ovary to the Society, which occurred in a patient with ascites. He tapped the abdomen, and noticed a small mass in the pelvis, which proved to be a fibroma about the size of a tangerine orange. He removed the fibroma and there had been no recurrence of the ascites. He thought that the deformity described was congenital.

Mr. RYALL asked if the diverticulum of the colon had been examined microscopically?

Mr. OVERY asked the same question, as he recently came across a cyst of the intestine much higher up, just below the duodenum. Three months later he found a diverticulum of the intestine with a short pedicle which was lined with typical intestinal mucous membrane and two muscular layers.

Dr. JELLETT said he thought the evidence was strongly in favour of the ascites having been of hepatic origin. It had been going on for a considerable time and it disappeared from the day of the operation and had not recurred. Moreover, it seemed to him impossible to account for the presence of a stump of tube in a case of congenital disease.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT LIVERPOOL, MARCH 16TH, 1906.

The President, Mr. R. FAVELL (Sheffield), in the Chair.

Mr. LLOYD ROBERTS (Manchester), showed a myomatous uterus removed by supravaginal hysterectomy after preliminary enucleation of four intramural fibroids. The patient, æt. 42, was anæmic after four years of menorrhagia, but was admitted for retention of urine; 40 ounces being withdrawn by catheter. Enucleation, as a preliminary step to hysterectomy, was recommended in certain cases as not only reducing the bulk, but also greatly increasing the mobility of the uterus and so facilitating its removal.

Sir W. J. SINCLAIR and Dr. FOTHERGILL (Manchester) showed a specimen with sections and drawing before removal of a sarcomatous growth of the labium majus in a girl, æt. 17. There was a large congenital pigmented mole over the labium and the right buttock. The growth was of two years' growth. It was not itself pigmented, and was composed of connective tissue continuous with that of the cutis vera, and very cellular in parts.

Dr. WALTER (Manchester) gave particulars of a case of abdominal hysterectomy for cancer of the body of uterus. The patient, æt. 58, was unmarried, and passed the menopause at 52. Although from the history the disease apparently extended over four years, no lymphatic infection was found in the pelvis during the operation.

Dr. WALTER also showed a specimen of intramural fibroid growing from the entire front wall of uterus and complicated by pregnancy at 3½ months. The patient's condition being serious on account of anæmia and increasing pain, abdominal hysterectomy had been performed. He did not advocate introduction of abortion in such cases, believing that abdominal section with enucleation or hysterectomy to be preferable, and less likely to be followed by septic infection.

Dr. A. W. W. LEA (Manchester) read a paper on the appendix vermiformis as a cause of pelvic inflammation, dealing with the literature of the subject

and analysing ten cases operated on by himself. He advised that the appendix should always be examined during gynæcological operations, and should be removed if "pelvic" in position, if pathological or adherent, or if near the stump of any removed organ. He had removed the appendix 35 times under such circumstances with no deleterious effect on the progress of the patients to recovery.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, MARCH 15TH, 1906.

FRANK T. PAUL, F.R.C.S., President in the Chair.

THE NEW LIVERPOOL CITY INFECTIOUS HOSPITAL, FAZAKERLY.

Dr. E. W. HOPE gave a short description, illustrated by numerous lime-light views, of the New City Hospital for infectious diseases at Fazakerly.

The hospital area was amply large, consisting of 118 acres, and had upon it two establishments, one for small-pox, containing 160 beds, another for the ordinary forms of infectious disease, containing 350 beds. The plan, construction, and arrangement were of the most modern type, and much advantage had been derived by visiting other hospitals designed with a similar object in other parts of the United Kingdom. The architect was Mr. Shelmerdine, the Corporation's surveyor. The institution would be officially opened in a few weeks, and would be under the supervision of Mr. C. Rundle, the Medical Superintendent.

THE TREATMENT OF CHOREA.

Dr. CHARLES MACALISTER read a note on chorea, in which he expressed the opinion that just as the rheumatoid fevers, which so closely resembled acute rheumatism, were due to an entirely different toxin, so chorea, which presented features associated with the rheumatoid diathesis, was probably due to a toxin different in its constitution, as well as in the effects it produced, from that of rheumatic fever. He discussed the various types of chorea, especially those which tended to be associated with endocarditis and joint pains as distinct from those which did not, and suggested that the conditions, although presenting symptoms in common, might be due to essentially distinct toxins. He referred to his view that the explanation of the long course of chorea depended on the poisons being neutral, as stimuli, to the organs of elimination, and that success in treatment would probably depend on the addition to the blood of some substance which would alter the constitution of the toxin and convert it into a stimulus for the skin or kidneys, which would then be able to remove it. Dr. Macalister had tried giving peroxide of hydrogen, especially in cases of chorea presenting skin eruptions (peliosis rheumatica), and he thought some benefit had followed its use.

CONGENITAL UMBILICAL HERNIA.

Mr. R. C. DUN read notes of a case of congenital umbilical hernia. The protrusion was large, being rather more than half the size of a child's head. It was covered, partly with true skin, partly by a thin membrane in which necrotic changes were taking place. The cord was attached to this thinned portion of the covering. The contents were irreducible, but not strangulated. Percussion gave a tympanic note. Operation was not attempted owing to the weakly condition of the infant, and he died of septicæmia on the sixteenth day after birth. An autopsy could not be obtained; the nature of the contents and coverings of the hernia was therefore not definitely ascertained. The large size of the hernia, its thinned coverings, and the wide separation of the recti muscles made it probable that the case in question was an example of the embryonal type of umbilical hernia, i.e., a persistency of the developmental condition which was normally present during the first three months of intra-uterine life.

Dr. F. W. BAKER YOUNG read a paper on the

INTRA-VENOUS INJECTION OF FORMIC ALDEHYDE FOR PULMONARY TUBERCULOSIS,

An abstract of which will be found on page 34. In the discussion that followed, Dr. ROBERT MAGUIRE, who was present as a visitor, in the course of an interesting speech, replied to his numerous critics, and stated that the method was entirely free from danger. It was not claimed that formaldehyde could cure all cases, but the results obtained were often very remarkable.

Dr. J. TORREY (formerly Professor of Chemistry in the University of Harvard), also a visitor, stated that in such dilute solutions any of the ordinary chemical reactions peculiar to formaldehyde would be extremely slow, and pointed out that it had been shown that condensation products of formaldehyde with more complex bodies were usually antiseptic; such reactions at least would not render formaldehyde inert toward bacilli.

Dr. A. G. GULLAN testified to the simplicity of this method. He thought the apparatus would be most useful in administering any kind of intra-venous injection. He had employed formalin in this way in three cases, and had never seen any harm follow, though about half the injections were followed shortly by rigors lasting about two hours. His first case was one of advanced acute miliary tuberculosis of the lungs which, after a slight temporary improvement, rapidly advanced and ended fatally. The other two cases were favourable ones in young men, in which beyond a diminution of moist râles, no improvement took place, and he doubted whether the same result could not have been got by other methods of treatment.

Dr. G. S. STANSFIELD said that he had welcomed Dr. Maguire's plan as a substitute for that of impregnating the air with formaldehyde. In January and February, 1901, he had treated six cases by this method, but was disappointed with the result. He quite agreed, however, with Dr. Maguire that there was no danger in the method, nor any great difficulty if the directions were closely followed. He thought hæmasepsin ought to be put on the market at a more reasonable price, considering the inexpensiveness of its constituents.

Dr. John Hay, Dr. R. J. M. Buchanan, Dr. C. Macalister, Dr. T. F. Young, Dr. J. Hill Abram, and Mr. W. Thelwall Thomas continued the discussion.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS. ABROAD. FRANCE.

Paris, March 24th, 1906.

TREATMENT OF CRUSHED LIMBS.

In cases of crushed limbs, amputation, according to Professor Reclus, should never be thought of; the treatment will simply consist in arresting hæmorrhage by tying any bleeding vessels or the placing of a few hæmostatic forceps.

After having immersed the wounded limb in a long bath of hot oxygen water (130°), the lesions should be irrigated with the same liquid and at the same temperature. The jet should be sufficiently strong to penetrate and clean out all the parts. Those which may seem to be almost destroyed could be removed by the scissors, but even here the greatest moderation should be exercised.

The chief point in the first part of the treatment is the employment of very hot oxygen water, which acts both as an hæmostatic and an antiseptic.

The second part consists in filling the wound with gauze coated with the following ointment:—

Antipyrine, 1½ drachms;
Salve, 1 drachm;
Boric acid, 1 drachm;
Iodoform, 20;
Phenic acid, 20;
Cor. sublimate, 2; Vaseline, 8 ounces;

and finally by a compressive dressing of absorbent wool. This first dressing should not be disturbed for several days, but as soon as the temperature rises or the dressing begins to smell the wound should be uncovered and immersed again in a bath of hot oxygen water.

If this mode of treatment did not appear sufficient to arrest infection, oxygen spray should be applied by means of the apparatus of Lucas Championnière, and be repeated frequently.

When the period of septic complications has passed attention should be turned to the process of elimination by nature, with a view of aiding it. For this purpose any parts that have lost sensibility should be removed as well as those which cannot be preserved.

Such is the treatment recommended by Professor Reclus, who for a long time back refused to practise amputation in traumatisms. It may be added that at present the majority of surgeons follow the example of the celebrated professor.

DYSPNOEA.

A new agent, termed "Oxafor," produced from the oxydation of camphor, gives excellent results in dyspnoea of every kind and from any cause. It is a white powder, little soluble in cold water, but more so in warm water; it may be given at the dose of one drachm daily. The following is a good formula:—

Oxafor, 2 drachms;
Proof spirit, 1 oz.;
Syrup of bitter oranges, 2 ozs.;
Water, 4 ozs.

The half to be taken during the day, or a tablespoonful every two hours.

Oxafor seems to diminish the irritability of the respiratory centres and regulates the respiration.

TREATMENT OF SCIATICA.

Who would not welcome an efficient and simple treatment for that affection, as frequent as it is troublesome, known as neuralgia of the sacro-lumbar plexus? Professor Launois, of the Tenon Hospital, furnishes the remedy which he now employs almost exclusively in his hospital practice. It consists in subcutaneous injections of a saline solution, approaching in its constitution physiological serum. It is as follows:—

Sulphate of soda, 10 grms.;
Chloride of sodium, 5 grms.;
Water, 1,000 grms. (1 litre).

Five grammes of this solution, slightly warmed, are injected over the painful points which Valleix has classified as follows: Lumbar, sacro-iliac, iliac, rotulian, femoral, retro-trochanterian, ischiatic, peroneal dorsal of the foot, malleolar.

It is in the neighbourhood of one or more of these points, where the painful sensations attain their maximum intensity, that the saline injections should be made.

Four, five, or six injections at different points may be made at the one sitting, while their depth varies naturally with the anatomical constitution of the regions and the situation of the nerve; while some are necessarily subcutaneous as near the ankle, others may be interstitial and deep as in the gluteal region. The injections may be renewed daily or every two or three days. They cause no pain.

Other forms of neuralgia, such as facial, intercostal, scapular, and lumbago can be relieved by the same simple treatment.

GERMANY.

Berlin, March 24th, 1906.

THE *Klin. Monatsch f. Augenhk* contains a report of a case of Extremely Acute Suppuration of the Nasal Sinuses, which affected the eyes also, by Dr. Cramer.

The patient, who had never had any trouble of the kind before, was suddenly attacked with severe frontal headache fever and reddening of the right half of the face. A fortnight later the right eye was so much chemosed that two sausage-like swellings, each the size of the thumb, protruded between the eye lids. The

projection of the bulb, however, was not great, nor was its motility much diminished. Near the inner corneal margin was a fistulous opening, from which offensive pus was freely excreted, the sound passed deeply into the orbit. Although percussion over the frontal sinus evoked no pains, empyema was more than suspected. Resection of the anterior wall of the sinus revealed an unusually large cavity; it contained no pus, but the mucous surface was raised by numerous vesicles. After curetting free opening and drainage through the nose were provided. In spite of this, free suppuration continued through the fistulous opening and the visual power steadily diminished. At a second operation the floor of the orbit was removed, on which the bulb burst, and the vitreous body escaped. The cribriform cells were full of pus and foul pus escaped from the antrum. In complete removal of the necrotic mucous membrane, chiselling of the anterior wall of the antrum was necessary. The enormous cavity was tamponaded from the *cavum fossæ* and also from the orbit. The case then went on well. The wound healed readily under frequent washings out. The conjunctival chemosis persisted a long time and was only overcome by temporary suture of the eyelids. The resulting disfigurement was now only slight. It was possible that the disease originated in a carious tooth, that was removed later.

PARAFFIN AND LIVING HUMAN TISSUES.

This subject is treated of by Dr. Eschweiler in the *Arch. f. Laryng. in Rhin.* Bd. 17. It had been reported by some observers that paraffin was not absorbed into the tissues, but that like other aseptic foreign bodies it became encapsuled by connective tissue. This was considered to be true as regarded hard paraffin, but as regarded soft paraffin connective tissues grew into it.

From microscopical examination of a saddle nose that had been "over corrected" by injection of paraffin and from which a piece had been removed for the correction of the "over correction," it appeared that the paraffin was completely absorbed and replaced by connective tissue, but that a long time was required for the process. The taking up of the paraffin was due to giant cells which "melted together from reactive proliferated fixed connective tissue cells." After the disappearance of the paraffin a backward transformation took place of the giant cells into epithelioid connective tissue, which on its part formed connective tissue fibres. Leucocytes and lymphocytes only played a subordinate role in the process.

The writer concludes from his observations that the definitive substitution of paraffin by connective tissue, and thereby the best surgical result, is brought about in the quickest and safest manner by making use of many small deposits of paraffin in place of larger ones.

At the *Verein f. Innere Medizin*, Herr A. Wassermann and C. Bruck gave

DEMONSTRATIONS OF THE ACTION OF TUBERCLE BACILLUS PREPARATIONS ON THE TUBERCULOUS ORGANISM.

They said that the cause of the specific reaction of tuberculous tissues after the injection of tuberculine was still shrouded in complete darkness. At present there were only hypotheses as to why the smallest dose of tuberculine reacted specifically on tuberculosis, how it rendered the tissues hyperemic and dissolved or melted them. They had now by the help of a new process succeeded in proving the presence of anti-bodies (antituberculine) in the human subject, in cattle and guinea pigs. These anti-bodies did not usually appear in serum, and never in healthy and non-tuberculous organs. This process was based on the phenomenon of complementary union on the coming together of "antigen" and anti-bodies, this being proved by an acceptor as indicator.

The appearance of anti-bodies gives easy conclusions as to the specific action of tuberculous preparations. By the "avidity" existing between tuberculine and anti-tuberculine, the tuberculine injected is drawn into the tuberculous organism which already harbours the antituberculine. The complementary combination

now taking place between tuberculine and anti-tuberculine explains further the specific reaction on the tuberculous tissues. By this combination the albumen-dissolving and digesting powers of the organism are concentrated on the tuberculous organ.

By the specific treatment of tuberculous individuals with tubercle-bacillus preparations, anti-tuberculine appeared in the blood circulation. If the anti-tuberculine in the blood is of sufficient amount the reacting power of the individual becomes extinguished, because the tuberculine injected is taken possession of by the anti-tuberculine and can no longer reach the tuberculous organ. In this point lay the limit of our present-day specific therapeutics with tubercle-bacillus preparations and further investigations, keeping these newly discovered relations in view, were necessary in order to carry our treatment a stage farther.

Hr. L. Michalis said he had made use of the same method in bringing anti-bodies into view after injection of organ cells. In association with Hr. Fleischmann he had injected an emulsion of guinea-pig's liver and he had obtained thereby a serum which, although it had no visible action on the liver cells of the guinea pig, neither *in vitro* nor *in vivo*, yet it was different from normal serum in that, brought into contact with the liver cells of the guinea-pig, it imparted to them the power of complementary combination. The method could therefore be made use of in many ways.

AUSTRIA.

Vienna, March 24th, 1906.

DUCTUS BOTALLI AND STENOSIS IN PULMONARY ARTERY.

At the *Gesellschaft für Innere Medizin*, Singer showed an anatomical preparation from a patient, æt. 26, who from childhood was white and bloodless, but never had palpitation till received into hospital. Five days before reception she was taken ill with fever pain over the region of the heart and difficulty in breathing. On reception she was pale, high temperature, frequency increased, but tension low.

There was pulsation in jugular with slight *voussure* or vaulting over the cardiac region; at the sternal ends of the second and third ribs on the left side were visible pulsations with a distinct systolic whirr. Percussion gave cardiac dulness two fingers breadth beyond the mamilla to the left, to the right, beyond the sternum below the fourth and fifth ribs.

Auscultation gave a systolic murmur at apex while the base gave murmurs with both systolic and diastolic. Both these murmurs were well marked in the right side as well as over the pulsating tumour in the second intercostal space on the left, where the systolic sound was louder, of a rushing, blowing character.

No sound was communicated to the carotid. In the left interscapular space both sounds were distinctly heard.

Shortly after her reception, dulness commenced in the left pulmonary apex, accompanied with all the symptoms of consumption. Fever, sweating, and hæmoptysis and subsequent infiltration with cavities.

Six weeks before death the vaulted swelling between the ribs subsided and the previous murmur could not be heard.

On opening the heart at the *post mortem* the ductus botalli was found persisting; the pulmonary valve was soft, but entire; but in the left side of the conus pulmonalis a firm, hard thrombus was closely adherent to the arterial wall. This clot extended down to the ductus botalli, which it closed. The origin being of recent date the presumption is that it coincided with the sudden disappearance of the tumour and murmur.

CONTENTS OF ERYTHROCYTES.

Schur exhibited preparations of blood with round, well defined bodies contained in the red blood corpuscle. These round bodies are of different sizes, but whose contents are of no definite structure. Their refractive properties make the peculiar bodies more prominent. They can be coloured with nuclear dyes such as

hæmatoxylin, methyl blue, gentian violet, pyronin, but not with methyl green or Erlich's tri acid. These bodies are found individually, scarcely ever duplicated. They are rarely central and usually found eccentrically. Beyond the discovery of this rare body the red cell corpuscle is quite normal and healthy.

Schur would hazard no hypothesis on the discovery. Nowhere in literature had such bodies been described nor apparently met with.

It might be well to mention the nature of the disease the patient suffered from, although he had examined many others suffering from the same disease but never met with the same phenomena. The preparations were taken from a patient suffering from morbus basedowii with well-marked exophthalmus and struma, but otherwise healthy. The large glands on the right side, and increased hepatic dulness were undeniable remnants of the disease, that had apparently much improved. Here and there a lymph cell could be seen in the blood, but these were rare.

He showed the blood of other four basedowii cases where their bodies were absent.

Sternberg thought the bodies were interesting to the profession, but attached very little importance to them, as they will be finally proved to be allied to the blood plates already found in the corpuscle.

Turk put a higher value on these round bodies than Sternberg, and assured him that they were not in any way associated with the blood plates.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

MUNICIPAL TREATMENT OF CONSUMPTION IN EDINBURGH.—The question of checking the spread of phthisis by the isolation of advanced cases in a special pavilion of the fever hospital is under the consideration of the public health authorities. In a statement on the subject, Councillor Gilson, Convener of the Public Health committee, remarks that the question is not one of philanthropy, nor is it one for the Parish Council. By far the greater number of those who die of phthisis are hard-working people, who pay their rates to the last. The town is justified, not on benevolent, but upon economic grounds, in protecting the lives of the citizens from the great danger of a powerful infection. If the dangerous cases which had got beyond the range of cure were provided for the prospect of a diminution of the disease in the city would be greatly improved. It is suggested that provision be made (in a disused scarlet fever pavilion) for 50 cases in the last stage of phthisis. The cost, upon the experience of the last five years, would not exceed one thousand pounds annually. The result would be the immediate abstraction of 50 sources of dangerous infection. In a similar institution under the municipality of Paris the experience is that the average duration of life of patients of this class is about 3 months, and thus some 200 cases would be received in a year. No expenditure of public money is more likely to yield an ample and immediate return. It is not unreasonable to suppose that in this way the mortality from consumption in Edinburgh would be reduced by 200 a year within the next ten years. Even taking it at half that, the average age at which we lose our people through consumption being 33, we may reckon that each life saved represents ten years of Labour. There is good authority for taking the wage earning power of each citizen at £35, and £35 capitalised at 10 years purchase means £350 for each saved life. A reduction of mortality, then, of only 100 lives per annum is cheaply bought by the expenditure named. In the report of the medical officer of health it is shown that the mortality rate from phthisis is 1.51 per mille—about 500 deaths per annum. A very considerable number are cases of respectable workmen and small tradespeople, and it is this class particularly who would be treated by the Council scheme.

ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH. The annual general meeting of contributors was held in the Hospital on March 14th, when the usual financial and statistical statements were submitted. The principal resolution, expressing the duty of the community to support the hospital, was proposed by Lord Dunedin, the Lord Justice General. In his speech, moving the adoption of the report, Mr. Hall Blyth, Chairman of the Board of Directors, spoke of the need for a convalescent home in connection with the hospital. The institution has recently had bequeathed to it a very suitable house in the country, and it is hoped that the public liberality will enable the directors to convert this into a convalescent home.

WOMEN GRADUATES OF EDINBURGH AND ST. ANDREWS AND THE FRANCHISE.—The action brought against the Universities by representatives of the women graduates for nominal damages on account of their refusal to issue voting papers to women was before the court of session the other day. The case was sent to the Procedure Roll, and will be debated after the vacation, on the resumption of the Court, in May. The feeling among the women graduates is unanimously in favour of proceeding with the action and having their legal position defined. The contention of the Universities is that women, like peers, are under legal disabilities as regards the franchise.

LIBERTON COTTAGE HOSPITAL FOR INCURABLES.—In connection with the Longmore Hospital for Incurables there has just been opened in one of the southern suburbs of Edinburgh the above Cottage Hospital. The Longmore Hospital was itself opened in 1875 with 22 beds, extended in 1883 to 50 beds, and again in 1886 and 1898 until now it accommodates 150 patients. For various reasons it was inadvisable again to enlarge the Longmore Hospital itself, and the managers resolved on having a separate building outside the city. Funds were provided by a bequest by Miss Martha Brown of £20,000, of which £6,000 was to be employed for building a cottage home for incurables suffering from consumption. The managers accordingly procured a site which would give room not only for such a building as could be erected out of Miss Brown's bequest, but for additional accommodation. The present Hospital, which was opened on the 19th by the Earl of Dalkeith, is thoroughly up to date in construction and equipment. It will accommodate 42 patients in all, 18 of these being consumptives, the remainder suffering from other incurable diseases. The cost has been about £500 per bed.

SCOTTISH ASSOCIATION OF REGISTERED MEDICAL WOMEN.—This association, which numbers among its members most of the women practising in Scotland, came definitely into existence a few days ago, when the constitution which had been under consideration for some time, was finally adjusted and agreed to, and the office bearers elected. The objects of the association are in general to safeguard the interests of medical women, and to consider educational questions which may from time to time arise.

BELFAST.

CASE OF ACONITE POISONING.—An inquest was held at Larne last week on the body of a man who had died after a few hours' illness with symptoms of irritant poisoning. It appeared that he had stewed something in a saucepan which he told his sister was bog bean, and took it to his bedroom with him in a mug. In little over an hour the sister heard a noise in the room, and on going in found him very ill. She got help and sent for the doctor, who arrived soon, but found the man dead. Dr. Wilson said that the roots, some of which he found in the house, were those of aconite. The jury found that the death was due to aconite poisoning, probably taken in mistake for bog bean.

TUGHAN v. DARNELL.—THE BELLADONNA POISONING CASE.—This action, at its third trial, has resulted in a verdict for the plaintiff, with £65 damages. The case was one of belladonna poisoning from the use of soap and belladonna liniment in a boy suffering from

orchitis after mumps, and Dr. Darnell was charged by the plaintiff with negligence. At the first trial the jury disagreed, at the second they found for Dr. Darnell, but this verdict was set aside on the ground of misdirection by the Judge, and a new trial ordered. As it is not yet settled whether an appeal will be lodged, no comment is possible at present. The trial has excited the keenest interest in medical circles here, and the court was crowded with medical men and students. Evidence was given by Professor Sinclair, Drs. O'Neill, John Campbell, McKisack, Kirk, McQuitty, Mitchell and Dr. Darnell himself.

QUEEN'S COLLEGE, DINNER.—The annual dinner of the Queen's College was held in the College Hall on St. Patrick's night, and passed off most successfully. The chair was occupied by Professor Lindsay, and among the guests was Professor Lorrain Smith, of Manchester, who received a very hearty greeting from his old colleagues.

PREVENTION OF CONSUMPTION.—At a meeting of the Ulster Branch of the National Association for the Prevention of Consumption held last week in Belfast under the presidency of the Lord Mayor, an address was delivered by Professor Caton, of Liverpool. He dealt particularly with the methods which are in use in that city, and gave a very hopeful account of their results. Ireland lags far behind the rest of the United Kingdom in this matter, and Professor Caton attributed this mainly to the want of proper education on the subject of tuberculosis, and rested his chief hopes of future improvement on the education of the young in simple rules of hygiene. Several medical men spoke at the meeting, and agreed in the main with Professor Caton's views.

LETTERS TO THE EDITOR.

"CONTRACT PRACTICE" AND THE BRITISH MEDICAL ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In common with many others of the profession I have received a painful confession from your contemporary *The British Medical Journal*, that we should all form a public medical service, or in other words, a dispensary, in connection with our practice. A penny a week for adults, and half this amount for children may be a profitable adjunct, but it is surely anything but ennobling for a profession. With Private Dispensaries, Public Medical Service, and Hospitals the profession surely does not require to be told so late in the day that the "British Medical Association is a company," which endorses this practice, though it does not recommend it. This is a nice distinction and quite worthy of any quack remedy. The company has fallen to a very low level when this form of advertising has to be resorted to. If the company were of any use to the profession that body would soon discover its merits and the efficacy of "contract practice." We have too much of it already and long for the "company" that would save us from such depraved deterioration.

I am, Sir, yours truly,
WM. MACVIE, M.D.

Booth, Liverpool, March 25th, 1906.

PROFESSIONAL ADVERTISING IN THE NEWS-PAPERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I cut the enclosed advertisement from *The Times* of Monday. Although I cannot hope that you will reproduce it in the very large type in which it appears, I trust you will give it publicity in your columns. It seems a pity that a book of such importance should not be brought to the notice of the President, Censors, and Fellows of the Royal College, which has the honour to claim the author as a diplomat, but this may be made certain by reproduction of the advertisement in THE MEDICAL PRESS. I have not noticed any announcement of any of the numerous editions of the work or reviews of it in the medical

papers; and this is a little astonishing in view of the fact that the book has been reviewed in terms of commendation by that great authority on science—and especially medical science—*The Queen*.

I am, sir, yours truly,

IGNORAMCS.

March 26th, 1906.

[The following is the advertisement to which our correspondent alludes, necessarily shortened to suit our space.—ED.]

New Edition (17th). Cloth, 1s. 6d. Boards 1s.
THE DIETETIC CURE OF OBESITY.

("Foods for the Fat.")

By DR. YORKE-DAVIES,
Roy. College Phys., London, &c.

Illustrates the dangers of Obesity, &c., &c.

OPINION OF THE PRESS.

The Queen says:—"The advice contained in this book will be invaluable."

REVIEWS OF BOOKS.

GILES ON GYNÆCOLOGICAL DIAGNOSIS. (a)

DR. GILES' work on gynæcological subjects is so well-known that a book from his pen on the subject of gynæcological diagnosis is sure to be received with approval on *a priori* grounds, and when the book has been studied it will be seen how deservedly the approval has been given.

The book consists of two parts. Part I. is entitled "General Considerations," and deals with case-taking, methods of examination, diagnostic instruments, and the interpretation of clinical signs. Part II. is entitled the "Diagnosis of Individual Cases." In it each chapter is devoted to a special "leading symptom"—amenorrhœa, pain hæmorrhage, discharge, pruritus, and so forth, and from this symptom the reader is carried back through the different conditions which can cause this leading symptom to the special condition from which the patient is suffering. Each chapter closes with a tabular synopsis of the causes of the particular leading symptom to which the chapter is devoted. There are thirty-five excellent illustrations, the work of the author. These serve their purpose admirably, and are worthy of special praise.

Dr. Giles has written this short work in a clear manner and in logical sequence, with the result that it is more valuable than we could have believed a work of the kind could be. Although it is short, almost all the essentials of diagnosis are included, the only omission of consequence which we have detected being the want of reference to the supreme importance of examination under an anæsthetic in doubtful cases. Personally, we never operate upon a doubtful case without first making such an examination, unless the condition of the patient forbids it, and therefore we should like Dr. Giles to make more pointed reference to its value in a second edition.

We strongly recommend the book to general practitioners and students who are desirous of obtaining a firm grasp of the principles of gynæcological diagnosis.

DISEASES OF INFANCY. (b)

THERE are few medical works which have given us greater pleasure or from which we have derived greater profit than we have received from the first edit on of the book before us, and it is therefore with sincere pleasure that we take the opportunity of reviewing its third edition. The most important changes which

(a) "Gynæcological Diagnosis: a Manual for Students and Practitioners." By Arthur E. Giles, M.D., B.Sc., F.R.C.S., Ed., Gynæcologist to the Tottenham Hospital; Surgeon to Out-Patients, Chelsea Hospital for Women. With thirty-five original illustrations. Pp. x. and 212. London: Baillière, Tindall and Cox. 1906. Price 7s. 6d.

(b) "The Diseases of Infancy and Childhood." By I. Emmett Holt, M.D., Sc.D., LL.D., Professor of Diseases of Children in the College of Physicians and Surgeons (Columbia University), New York. Third Edition, revised and enlarged. Pp. xix. and 1,174. With 241 illustrations, including eight coloured plates. London: Sidney Appleton. 1905.

have been made in this edition are to be found in the articles upon the following subjects:—Examination of the Sick Child, Hypertrophic Stenosis of the Pylorus, Diarrhoeal Diseases and Dysentery, Vaginitis, Cerebro-Spinal Meningitis, Mental Defects, Chondro-Dystrophy, Status Lymphaticus, and Diphtheria. Most of these chapters have been entirely re-written, and some of them appear for the first time. The author has also wisely added to and otherwise improved the illustrations, and altogether has added twenty-five new ones.

The book itself is divided into ten parts, which deal respectively with General Conditions; Diseases of the Newly-Born, Nutrition, Diseases of the Digestive, the Respiratory, the Circulatory, the Uro-genital, and the Nervous Systems; Diseases of the Blood, Lymph Nodes, Bones, &c.; Specific Infectious Diseases; and other general diseases. Perhaps one of the most interesting parts is that dealing with nutrition. In spite of the fact that it is just a little over-weighted with statistics, it furnishes most interesting reading, and at the same time is valuable to anyone who desires to look up a special point, so full is the information which it contains.

In the chapter on the care of premature and delicate infants, we are glad to see that Dr. Holt ascribes the incubator he depicts to its correct origin, inasmuch as an attempt has been made by an ingenious American to credit himself with its invention.

Space forbids us to review Dr. Holt's work at great length; suffice it to say that in style, arrangement, and subject matter it leaves little to be desired, and is, indeed, a model of what a text-book of the kind should be.

CONGENITAL MALFORMATION. (a)

THIS short monograph on congenital abnormalities of the limbs is an interesting account of a series of cases illustrating the rarer forms of mal-development of the arms and legs. The author's reason for publication is a desire to throw light upon the etiology of such conditions by adding to the number of recorded cases and by giving a full account of each. Most of the variations which he describes have been observed previously, but this pamphlet is none the less of value to readers of the German language, and for the sake of the illustrations alone is pretty certain to attract the attention of students of embryology and teratology. Most of the figures are excellent, but it is a pity that the author was so sparing in his reproductions of skiagraphs. Those that are figured are for the most part taken from the less rare abnormalities, while some of the most interesting cases of his collection are only illustrated by ordinary photographs. Examples of polydactylism and syndactylism are described, and also many cases of congenital absence of various bones, and cases of gigantism or dwarfism of limb or portions of limbs. A very good description and figure is given of an abnormality to which we think sufficient attention has not been directed, namely, tapering of the arm from the elbow down to a pointed extremity consisting of a single finger. Another rare defect is that described on page 3, and consisting of a club-shaped hand with a well-developed thumb and little finger situated in the lateral aspects of the tumour-like extremity.

THE BACTERIOLOGY OF PERITONITIS. (b)

THE work before us has been built up on the basis of the Erasmus Wilson Lectures of 1905, and is an attempt to place the bacteriology of acute peritonitis upon a sound basis. The authors in the course of their work have made systematic examinations of the peritoneum in 270 cases operated upon at St. Thomas's

Hospital during a period extending over some sixteen months. The subject which the authors have selected is, so far as British writers are concerned, an almost unbroken field. That they have made the best use of their opportunities will, we think, be obvious to anyone who carefully reads their valuable addition to medical knowledge before us.

The first chapter deals with the functions of the peritoneum, and it is perhaps one of the most important, as it gives the clue to the writers' ideas generally on the subject of peritoneal infection. It commences by referring to the power of absorption of the peritoneal cavity—a power which the writers are careful to point out is due not as was formerly held to be the fact that the entire peritoneal cavity is a huge lymph sac (which it is not), but to the extraordinary rapidity with which fluids can be taken up through the inter-tendinous pits of the diaphragmatic peritoneum. Any further absorption which occurs, occurs through the blood-stream, to which the fluid gains access through rents or stripped spots in the peritoneal endothelium. On the latter account, the writers deprecate the pulling off of fibrinous plaques at an operation, as opening thereby an additional route by which infection can reach the blood stream.

The virulence of micro-organisms is next mentioned, and the writers refer to the well-known fact that in some cases large quantities of pus make their way into the abdominal cavity without causing serious after-consequences. This is explained by the low vitality of the invading organism in such cases, an explanation which fits in well with the experience of clinical surgeons. The consideration of the relative virulence of the different organisms met with in acute peritonitis follows, and occupies some pages. The streptococcus is regarded as at once the most unusual and the most deadly invading organism. Next to it, in point of virulence, though of very much more common occurrence, comes the bacillus coli, and the authors definitely register their opinion that it plays by far the largest part in hurrying patients from the wards to the *post-mortem* room. The staphylococcus albus, on the other hand, receives a very different character. It is held to be the organism which is the first to make its appearance in the peritoneal cavity after the occurrence of a lesion; it is of very low virulence. It is found at the spreading edge of more acute infections, and so it is believed to exercise a protective action by determining the advent of phagocytes and the setting-up of limiting adhesions.

From the results of their experiments, the writers believe that it is possible to make a prognosis from the microscopical examination of films taken from a remote region of the peritoneum in cases of infection. If phagocytes are abundant and staphylococci are present, the prognosis should be favourable. If bacilli are also present, but cells and cocci abundant, the prognosis is more grave, but is still not hopeless. But if cells are scanty and disintegrated, and bacilli are alone present, or, if streptococci are found, the case may be regarded as hopeless.

We have dealt shortly with this opening chapter of the book before us. Chapters II. to XIV. are devoted to the different forms of infection and the different infecting organisms, but want of space forbids our entering into a similar discussion in their case. The last chapter deals with the treatment of acute peritonitis based upon its bacteriology. Stated in a few words, the authors consider that, in acute streptococcus infection, if there is any prospect of success, it must lie in the most thorough washing possible. In colon infection, on the other hand, they believe that limited operations should be the rule, because of the mechanical impossibility of cleansing the peritoneum, the risk of washing away the phagocytes in the limiting exudation, and the danger of spreading infection. Their view on drainage we must leave to our readers to ascertain for themselves, save to quote their aphorism that "the cases which it is most advisable to drain are the very ones where drainage is impossible, whilst in

(a) "Upon Congenital Malformation of the Extremities." By Prof. F. Klausner, Munich. With thirty-two illustrations in the text. Wiesbaden: J. F. Bergmann. 1905.

(b) "The Bacteriology of Peritonitis." By Leonard Dudgeon, M.R.C.P., Bacteriologist to St. Thomas's Hospital, London, and Percy Sargent, M.A. M.B. (Cantab), F.R.C.S., Surgeon to Out-Patients, Victoria Hospital for Children, Chelsea, &c. Pp. xii. and 243. London: Archibald Constable and Co., Ltd. 1905.

those where it is possible it is also unnecessary." On the subject of drug treatment, they are very definite—"It is obvious that the teachings of bacteriology harmonise with those of clinical experience, in pointing to purgatives, and not to opiates, as the right drugs to be given in peritonitis."

HANDBOOK OF PHYSIOLOGY. (a)

FLINT'S "Textbook of Human Physiology" appeared in America in 1875, and held sway in the land of its birth for well-nigh thirty years. In this country it also had, for several years, "a local habitation and a name" as a useful and reliable text-book of physiology.

The "Handbook" before us takes the place of the text-book of thirty years ago, and the author tells us that it contains little of the former text, except parts relative to descriptive anatomy and established views that have become classic.

It might be fairly asked at the outset, What has a present-day text-book of physiology to do with descriptive anatomy? It is, of course, true that without a knowledge of structure a proper knowledge of function is impossible to acquire. But the day is past when a text-book of physiology can assign more than one-third of its space to physiological anatomy and histology, notwithstanding the author's appeal to experience as his justification.

It is always difficult to put "new wine into old bottles" with satisfactory results, and while every one respects the venerable and distinguished author of the text-book, it must be confessed that his attempt to rejuvenate his work constitutes no exception to the rule. Reference is undoubtedly made to recent advances in the science of physiology, but the old Adam is revealed on every page. A few examples will suffice. Carbon dioxide is said either to diffuse from the venous blood into the lungs or to pass out by a process "known as dissociation." Along with deficiency of oxygen, "animal emanations" account for the distress and fatal results of breathing in a confined space. "No particular part of the body is endowed with the special office of calorification." "All physiologists are agreed that the quantity of heat produced by oxidation is the same, whether the combustion be rapid or slow." Urea is synthesised by combining ammonium sulphate with potassium without further detail, and the proposition that the amount of this substance excreted in the urine depends largely on the nature of the food it is supposed to require, and is given serious defence. Many similar "quaint conceits" appear throughout the work, but it is unnecessary to multiply instances.

The book is, however, by no means devoid of merit. Chapter XI., which deals with "Secretion," contains a goodly store of useful information not found at such length in recent physiological text-books. Many of the illustrations also are beautiful, particularly the frontispiece, and the four illustrations borrowed from Dalton's "Topographical Anatomy of the Brain." A useful atlas of histology and embryology, containing sixteen plates with over sixty figures in colours, is given at the end. Those borrowed from Sobotta's "Hand Atlas of Histology" have lost none of their beauty in reproduction; so much can hardly be said for those taken from Wilson's well-known atlas of Karyokinesis, &c.

The most serious defects of the book are that it seemingly evades the true inwardness of things, and does not reveal the trend of modern physiology to its readers. It awakens no interest in the problems that still remain unsolved—the living vital aims of physiology—many of which engage the thoughts and activities, not alone of physiologists, but of all medical men imbued with an interest in the advance of their sciences. In these respects it stands in marked contrast to some other recent American works on the subject to which the author possibly refers when, prior

(a) "Handbook of Physiology." By Austin Flint, M.D., LL.D. New York: The Macmillan Co.

to the appearance of the present Handbook, he felt obliged to use more modern works for class recitations, instead of his old "Text-Book" which had got out of date.

OBITUARY

SURGEON-GENERAL JOHN LUMSDAINE.

SURGEON-GENERAL JOHN LUMSDAINE, of the Indian Medical Service, retired, died on March 11th at Weston-super-Mare, aged 79. He served in a boat expedition against El Khatiff in the Persian Gulf. Later he served in the Bombay Horse Artillery during the campaign in Central India in 1857-58-59, under Sir Hugh Rose, was present at the capture of Ratghur, the action of Baroda, the relief of Saugor. He was specially mentioned in despatches, and received the medal and clasp. For the Abyssinian expedition of 1867-68 he received the medal, and was specially promoted to substantive rank of surgeon-major for "valuable services" in the field. He retired in 1883.

DR. J. M. H. MARTIN, OF BLACKBURN.

We regret to announce that Dr. Martin, of Blackburn, died suddenly at his residence on March 20th. Deceased, who was a Borough Justice, recently occupied the post of President of the Lancashire and Cheshire branch of the British Medical Association, and he had for many years been the leading surgeon of Blackburn. He was medically educated at Edinburgh University, and took the qualification of M.D. Vict. in 1892.

Conferring of Degrees at Leeds University.

A CONGREGATION of Leeds University was recently held, at the School of Medicine, for the purpose of conferring degrees. The vice-chancellor (Dr. N. Bodington) presided. Professor Grant (Dean of the Faculty of Arts) presented Mr. T. P. Sykes, of Bradford, for the degree of M.A., *Honoris Causa*. Mr. Sykes is this year the President of the National Union of Teachers, and he has a long and honourable record as a teacher and as an organiser of teaching in the city of Bradford. Professor A. Smithells (Dean of the Faculty of Science) presented for the degree of M.Sc., Mr. Charles Bothamley, Mr. Aldred Farrer Barker, and Mr. Walter Myers Gardner, former students of the Yorkshire College. Mr. Barker and Mr. Gardner are professors of the technical college at Bradford, and Mr. Bothamley is engaged in educational work (primary and secondary) in the county of Somerset. Dr. De Burgh Birch (Dean of the Faculty of Medicine) presented Mr. James Stirling Crawford, Mr. Roland Brooke Radcliffe, and Mr. Albert Latimer Walker for the degrees of M.B. and Ch.B.

The Survival of the Unfit.

THE Ulverston Guardians have referred to the Local Government Board the case of a family where the father died in an asylum, the mother was feeble-minded, there were seven daughters and about a dozen illegitimate children. Several were chargeable to the Union, and one of the daughters is now in the workhouse awaiting her confinement. The family have cost the ratepayers an enormous sum, and the guardians are of opinion that drastic measures should be taken to cope with such an evil.

The Government Vaccine Lymph.

IN reply to a question in the House of Commons last week, the President of the Local Government Board said:—The lymph supplied from the National Vaccine Establishment is, in all cases, derived direct from the calf, has been passed through a series of calves, and is in no instance directly derived from the artificial inoculation of calves with human small-pox. The usual method of renewing lymph for supply from the establishment is by vaccinating calves with vaccine lymph obtained from children, but it cannot be stated that this is always so.

MEDICAL NEWS IN BRIEF.

Honour to Professor G. Sims Woodhead.

DR. SIMS WOODHEAD, the distinguished Professor of Pathology in the University of Cambridge, was entertained to breakfast by the Temperance Collegiate Association on the 20th inst., in the rooms of the Christian Institute, Glasgow, where he delivered a stirring address on the evils of alcohol on the human body. Later in the day, he was entertained to dinner by the Corporation of Glasgow, where many of the leading medical teachers were present. He subsequently paid a round of visits to several of the hospitals and institutions.

A Hospital for Gentlewomen.

ON Thursday last, at a meeting held in London to consider a scheme for providing a hospital for gentlewomen, Sir Roper Lethbridge (Chairman) said that such a hospital was a necessity for ladies whose pride naturally prevented them from going to the ordinary hospital, where the environment was often distasteful. And even if they were able to afford three guineas a week as paying inmates, the accommodation was very limited, and they could not have their own medical men, as they would under the new scheme. The sum of £20,000 would make the hostel self-supporting, and they appealed to the public for that amount. Already £600 had been obtained, and with £5,000 the work would be begun.

University College Hospital.

At the annual meeting of the Council and subscribers of this institution on Thursday last, the chairman, Lord Monkswell, said that the number of out-patients treated had increased very considerably during the past year, partly owing to the temporary closing of two neighbouring hospitals, leaving them with a total indebtedness of £11,234 7s. 1d. The balance available to meet this large debt was £3,261 8s. 4d. The committee viewed the financial state of the hospital with much alarm, and feared that, unless liberal support was forthcoming very shortly, they would be compelled to resort to the sale of a further portion of the small remaining investments available for general purposes. The only alternative would be to close a portion of the hospital, and thus curtail the immense benefit which Sir Blundell Maple had conferred on the poor of the district and of London generally by his splendid gift.

Bequests to Medical Charities.

UNDER the will of Mr. Vyall Edward Walker, D.L., J.P., of Southgate, and a member of the well-known brewing firm of Messrs. Taylor, Walker and Co., the following bequests, all free of duty, go to the following medical charities:—£2,000 to the London Hospital, £2,000 to the Cancer Hospital, Brompton, £1,000 to the Middlesex Hospital, £1,000 to the City of London Hospital for Diseases of the Chest, £1,000 to the Royal Hospital for Incurables, Putney, £1,000 to the Poplar Hospital for Accidents, £1,000 to the Idiot Asylum, Earlswood, £1,000 to the Hospital for Consumption at Brompton, £1,000 to the Victoria Hospital for Children at Chelsea.

Commission on "Sleeping Sickness."

HIS EXCELLENCY the Governor-General of the Sudan has directed that a Commission be appointed to investigate the possibility of the extension of "Sleeping Sickness" into Sudan Territory. The Commission to be as follows:—Lieutenant-Colonel G. D. Hunter, D.S.O., P.M.O.E.A., Dr. Andrew Balfour, Director Wellcome Research Laboratories, Khartoum, a British medical officer, Egyptian Army, or medical inspector, Sudan Medical Department, or such members as may be hereafter appointed. Points to be investigated:—(1) To ascertain the distribution of various species of tse-tse flies or other biting flies in the Sudan; (2) to

ascertain if the disease at present exists in Sudan territory; if so, to determine the exact areas, and to what extent the distribution of the disease coincides with the presence of the tse-tse or other flies in these areas; (3) a systematic investigation of the blood of a population in an infected district; (4) a thorough and complete research into the character of the disease, specially as regards its origin and spread.

Hospital Sunday Fund.

THE question of applying for the incorporation of the Metropolitan Hospital Sunday Fund by Royal Charter or otherwise was considered at the Mansion House meeting. The Lord Mayor presided. The Rev. Canon Fleming said that at present the fund was without power to make by-laws, and generous contributors like Mr. George Herring (who gave something like £1,200 annually) had no vote. The Rev. Hardy Harwood pointed out the effect of the incorporation in safeguarding the continuity of the fund. There was no desire on the part of the council to close the door against frank and friendly discussion of the methods and the hospitals with which they were concerned. Dr. Adler, Chief Rabbi of the Jewish congregation in London, supported the resolution proposing incorporation, which was carried unanimously.

Trinity College, Dublin.

At the Hilary Term, 1906, the following passed the Preliminary Scientific Examination:—

Physics and Chemistry.—James H. Crane, George Halpin, Richard H. Mathews, William P. H. Smiley, Benjamin A. Molyneux, Beatrice M. Hamilton and Henry H. James (equal), Herbert V. Stanley, John T. M'Donnell, James Beckett.

Botany and Zoology.—John A. W. Ponton, Albert V. J. Richardson, and Desmond Drew (passed on High marks); Duncan F. Hunter, William H. Hart, James P. S. Dunn, Walter E. Adam, Brindly H. Moore, Hans Fleming, Charles O'Brien, Edward H. Murphy, Patk. F. Nunan, Samuel R. Richardson, and Bethel A. H. Solomons (equal); Edward Garland, Victor B. Kyle, and Hugh S. Metcalfe (equal); Gervase Scroope and William H. Sutcliffe (equal); John W. Flood and Frank R. Seymour (equal).

Intermediate Medical, Part I.—Samuel F. A. Charles, William E. Hopkins, Gerald G. Mcreedy, Norman P. Jewell, Dixie P. Clement, Alfred H. Smith; Charles W. Laird and Frank R. Seymour (equal); Ernest C. Lambkin, Henry H. Ormsby, and Robert de C. Wheeler (equal); James F. Clarke, Alexander S. M. Winder, Frederick A. Anderson, William H. McCarthy, Henry R. Kenny, John H. Morton, William E. M. Armstrong, Frank Smartt, Julian B. Jones.

At present, there are three vacancies on the surgical side and two vacancies on the medical side of the dispensary of the Glasgow Royal Infirmary. We hear there is a keen contest for the posts.

A COMMERCIAL traveller and eight medical students were summoned at Leeds last week for taking part in a disturbance at the Tivoli Music Hall on the 14th inst., arising out of a performance conducted by "Doctor" Walford Bodie, who operates upon persons suffering from paralysis. During the disturbance the police were called in, and the rioters, numbering nearly a hundred, were ejected after a severe struggle. Several of the officers received blows from the rioters, most of whom were armed with sticks, which they used freely, and considerable damage was done to the internal arrangements of the building. It was alleged that the police had used their batons, but this was denied, although it was admitted they protected themselves with sticks and other weapons, which they wrested from the rioters.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

Lymphatism as a Family Disease.—Hedinger (*Deut. Arch. f. Klin. Med.*, 1905) calls attention to the fact that the condition known as lymphatism may occur as a family disease. He mentions a case of a family of nine children, five of whom died suddenly during infancy. In some instances the child simply became cyanotic, lost consciousness, and died in a few minutes. In other cases the picture was that described as thymic asthma. Hedinger cites reports of a number of other observers recording the death under similar circumstances of from two to nine children in single families. The lesions found in such cases are constant, though varying in degree, and consist of enlargement of the thymus and of the lymphatic apparatus, the latter sometimes affecting single groups of glands, but more often involving also the lymphatic tissue of the spleen and the intestines. The microscopic lesions resemble in many ways those of an infection, though bacteriologic examination is negative. The pathogenesis is very obscure. The possibility of an auto-toxæmia has been suggested, but merely on the ground of the histologic resemblance of the lesions to those of a bacterial infection. D.

Sudden Death in the Course of Eczema.—Bernheim-Karrer (*Jahrbuch f. Kinderheilkunde*) discusses the mystery of sudden deaths in children with eczema of the scalp and face. In one such case the autopsy revealed an unsuspected streptococcal focus in one lung, the secondary action of these germs having induced slight endocarditis and pleural effusion. In another case an infant with eczema exhibited attacks of heart weakness, possibly from a similar action of the germs on the heart muscle. Another child of eleven months was under his care for recurring eczema of the scalp and face. The child was brought to him, after two months absence, on account of a new patch on the cheek, and he was impressed with the dull look in its eyes, but nothing abnormal could be detected in lungs or heart. The cervical glands were swollen. The child seemed unusually quiet, and was found dead the second morning. Staphylococci were discovered in the cutaneous lesions and in the internal organs. Their numbers were not arge, but it is possible that the eczema may have generated toxins, similarly to extensive burns, which may have induced an actual toxic form of staphylococcus mycosis. This assumption was confirmed by a number of experiments on animals. Infection with the staphylococcus alone did not cause, by any means such severe symptoms as when the staphylococcus infection was supplemented by a cutaneous lesion, such as a croton oil blister. The heart seemed to suffer particularly in these cases. The researches reported emphasise the importance of careful observation of the heart's action in cases of extensive eczema. Possibly the blood-pressure might afford useful information. D.

Treatment of Exophthalmic Goitre by a Specific Serum.—Rogers (*Journal of the American Med. Assoc.*, Feb., 1906) records ten cases of exophthalmic goitre treated by a specially prepared serum. He obtained two large soft cellular thyroids from cases of exophthalmic goitre. The glands were ground to a pulp, extracted with normal salt solution, and the coarse fibres strained off. After adding acetic acid, the supernatant fluid was syphoned off and the remaining nucleo-proteids and globulins, including thyroglobulin, were thrown down by half saturation with ammonium sulphate. These precipitates were combined and injected into rabbits. The rabbits showed a severe reaction and some died. After five weeks of this

treatment the rabbits were bled from the carotid, and the serum collected. Other rabbits were treated with the nucleo-proteids and globulins after the precipitates had been dried for some months. The dose of the serum used in treating the patients was about 1 cc., and two or three injections were sufficient. In every case benefit resulted, complete cure occurring in seven cases in the course of three or four months. Three of the cases thus cured were exceedingly bad. Both local and constitutional reactions followed the injections, but not of an alarming nature. Rogers points out that the utmost care in attention to detail in preparation of the serum is necessary. Owing to the difficulty in procuring diseased thyroids, this serum can hardly be put on the market. D.

Value of Lumbar Puncture in Diagnosis.—Gerhardt (*Grensgab d. Med. u. Chirurg.*, Bd. 13), as a result of his investigations, comes to the conclusion that lumbar puncture is of the greatest value in the diagnosis of tuberculous and purulent meningitis, since, by an examination of the fluid obtained, with reference to its bacteriological contents, its cytology, and its albuminous contents, one can not only determine whether meningitis is present or not, but also the form of meningitis. In acute febrile diseases lumbar puncture frequently enables one to distinguish the symptoms of severe toxæmia from those of actual inflammation of the meninges. The presence of blood in the fluid may confirm a diagnosis of hæmorrhage into the lateral ventricle of the brain, or fracture of the base of the cranium, or, more rarely, of spinal injury. In cases when doubtful brain symptoms are present, an excess of lymphocytes in the fluid may suggest syphilitic brain disease, but the author expresses doubt as to whether any information of value can be obtained in cases of suspected tabes. He lays stress also on the therapeutic value of the procedure, maintaining that in cases of cerebral tumour, headache and giddiness are often much relieved owing to the lessening of pressure produced. M.

Stokes-Adams Syndrome.—Lichtheim (*Deut. Arch. f. Klin. Med.*, Bd. 85, Heft. 3) reports a case of this rare disease. The patient presented very marked tachycardia (there being twenty-five pulse beats per minute in the radial artery as compared with eighty-five jugular pulsations), and he also suffered from giddiness and syncopal attacks. The cardiac dulness was increased in every direction, and a systolic bruit was audible all over the heart, but most intense at the base. The second sound was quite pure. Sphygmographic tracings showed that the jugular pulse was not a mere multiple of the arterial pulse, and that the rhythm of the auricular contraction was quite independent of that of the ventricles. Its independence was shown later in the pulse counts, namely, thirty radial pulsations to seventy-one jugular pulsations. Lichtheim regards the case as one of heart block, and believes that it is produced by a destruction of the connecting muscular band between the auricle and the ventricle, which extends into the ventricular septum from the posterior auricular wall. This was most probably brought about by arterio-sclerosis. Belski (*Zeitschrift f. Klin. Med.*, Bd. 57, Heft. 5) also reports a case, and expresses the opinion that the condition is a result of auricle-ventricle arrhythmia leading to independent action of the cardiac chambers. M.

The Use of Isoform in Dermatology.—Isoform is a non-poisonous, insoluble substance occurring in crystalline form and possessing strong antiseptic properties. It can be used as a powder mixed with an

equal part of calcium phosphate, and can be made up into a paste with glycerine. Necker (*Deut. Med. Woch.*, No. 38, 1905) reports that he has used it extensively in his surgical clinic, and especially in sixty cases of venereal ulcers. In most cases he used at first the 50 per cent. powder, and then later a 10 per cent. powder made up with the calcium phosphate, and he speaks well of the results. The ulcers healed up very quickly, and the tissue destruction soon came to an end. He has also employed it as a paste for the treatment of balanitis, but finds that it tends to irritate mucous surfaces. In one patient a scarlatiniform eruption followed by a pustular eruption followed the packing of an abscess with gauze impregnated with 5 per cent. isoform, and in five other cases he also saw unpleasant sequelæ to its use. On the other hand, when patients possess a good resisting power, the drug is most valuable as an antiseptic, and is especially good for mycotic skin affections, such as tinea versicolor and ringworm. In gonorrhœa also he has employed it as a $\frac{1}{4}$ per cent. emulsion, and has found it especially useful in treating post-gonorrhœal urethritis. M.

Treatment of Cancer of the Oesophagus by Radium.—

Max Einhorn contributes a paper on this subject to the Carl Ewald Fest-Number of the *Berliner Klin. Woch.* He points out that the nature of the affection naturally leads the physician to attempt its cure by experimenting upon it with every new remedy that seems at all likely to prove of use. Accordingly X-rays were largely employed soon after their discovery, but unfortunately proved of little value. The discovery of radium and of its wonderful properties suggested that it might be more successful, especially as from its nature it would be possible to bring the radium into close apposition to the growth. Einhorn then describes his apparatus, which consists of an œsophageal bougie provided with a hollow metal cap. Into this cap the radium is mounted and the bougie is then passed down as far as the stricture and is left *in situ* for from a half to one hour. Since a previous paper on the same subject in January, 1904, the writer has treated in all seven cases. In each of these the diagnosis was undoubted. One of them was a private patient, æt. 75, suffering from a very tight stricture. He was treated every second day during a period of two and a half months, the time of exposure to the action of the radium being half an hour on each occasion. His condition improved very much under treatment, and he soon became able to take fluids with comparative ease, and even semi-solid material, whereas before treatment, fluids could only pass the obstruction with the greatest difficulty. The six other cases were treated in hospital, and all of them showed improvement, the most pronounced effect being a widening of the stricture accompanied by a greater ease in swallowing, and by a general improvement in the condition of the patients. Pain also was relieved in most of the cases. The writer regards the results as very promising, and looks forward to a confirmation of his experience from other clinics. M.

Gout and its Causation.—Walker Hall (*Pract.*, March, 1906) reviews our knowledge of the causation of gout in the light of recent advances in pathological chemistry. Though we have still much to learn concerning the circulation of uric acid in the tissues and of its capacities for combinations in them, as an etiological entity, it must be definitely discarded. Hall then proceeds to discuss the new hypotheses which have been evolved to replace that which considered uric acid as the prime etiological factor. The view that gout is of bacterial origin, probably by infection through the intestinal mucosa, has been urged by many writers, but Hall says: "We are really not yet in a position to discuss this bacterial theory of gout. Except that adequate clearance of the intestinal contents diminishes the gouty symptoms, we have not much evidence to go upon." Kionka and Frey have put forward a very attractive hypothesis in which the presence of "gly-

cooll" plays an important part. Hall himself, and others have found that excessive meat feeding in dogs produces degenerative changes in the liver and kidneys. In man, anatomical changes have not been demonstrated in the liver in gout, but this does not negative the possibility of there being functional damage. It seems certain that glycooll or certain amino-acids from which glycooll can be readily split off, is formed during the proteid metabolism, and is normally converted into urea by the liver. It would appear from the result of Hall's investigations that some glycooll is present in the normal urine, but that it is found to a much larger extent in the urines of the gouty. "When a solution of glycooll is added to a neutral solution of dialkali-urate the appearance of the (acid) monoalkali-urate is hastened, the action being more pronounced when the sodium salt is used. Urea, on the other hand, inhibits the formation of the acid salt, but loses its powers when glycooll is added to a solution of neutral dialkali-urate and urea. If glycooll is present in gouty urine, it may be supposed that glycooll is also present in the tissue fluids, and thus the precipitation of urates may be favoured." It is, however, denied that glycooll is to be found in the damaged cartilages of the gouty, as stated by Kionka and Frey, and Hall has shown that the excretion of glycooll in the urine is by no means limited to gouty patients. Hall concludes by saying that in spite of these various and probably fallacious hypotheses our knowledge of the intermediate stages in gouty metabolism is making steady progress, and our increased knowledge can already be turned to good account in treatment. K.

Hydatid of the Lung.—Mould (*Jour. Roy. Army Med. Corps*, March, 1906) describes an interesting case of this condition which ended in complete recovery. The patient, æt. 40, had served six years in India. For about sixteen months he had had fits of coughing at irregular intervals during which he spat up some blood. Some seven months before admission to hospital he had been examined by two medical officers, but nothing was found wrong with him. Since that time till his admission to hospital he had not had another attack. The present attack came on while route-marching, when he was suddenly attacked by severe pains in the chest and coughing. The cough lasted about a quarter of an hour and was attended with some blood spitting, and then a piece of dense white membrane came away, after which he got relief. Examination of the chest showed that the expansion was equal on each side, but on the left side there was absolute dulness to percussion over an area extending from the clavicle down to the third interspace both in front and behind. Over the dull area the breath sounds were completely absent, and vocal resonance and tactile fremitus were also absent. The left radial pulse was much smaller than the right, and was scarcely perceptible when the arms were held above the head. The heart was considerably dilated, but the sounds were normal. Several further attacks of coughing occurred, and pieces of membrane with blood-stained mucus were brought up. The membrane was examined, and hydatid hooklets found, which established the diagnosis. He was treated with rest and inhalations of creosote. In about a month he was discharged from hospital quite well. The pulse was equal on each side, the heart was normal in size and the lung had completely cleared up, except for a small dull patch about two inches in diameter just at the outer end of the clavicle. K.

NOTE.—A summary will appear each week in the following sequence:—

- (1) "Recent Medical Literature."
- (2) "Recent Surgical Literature."
- (3) "Recent Gynecological and Obstetrical Literature."
- (4) "The Recent Literature of Physiology, and Pathology."

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

DR. H. T. (Amsterdam).—We hope to refer to the subject of your communication in our next.

THE MEDICAL DEFENCE UNION.

In the annotation referring to the successful prosecution by this Society of a quack calling himself Dr. Muschik (page 300 of our last issue), the name of Mr. Tyrrell, "the man in perfect health," who consulted the quack and was treated by him as a fever patient, was, by an obvious slip of the pen, represented as the impostor who was fined, whereas he (Mr. Tyrrell) was the private detective employed by Mr. Hampson, solicitor to the Medical Defence Union, and was the means of bringing the quack to justice. We greatly regret the error on our part, and apologise to Mr. Tyrrell if it has caused him any annoyance.

OPSONIC INDEX.

MR. H. W. HAMILTON.—The statement was published some time back that exercise increased the opsonic index. If that be the case it explains the beneficial effects of routine walking exercise upon consumptives. We have not the exact reference at hand, but the series of observations upon which the above statement was founded was made by two medical men at a sanatorium for consumption. If you wish we will gladly furnish you with chapter and verse.

H. A. C.—We are unable to devote space to the matter, as it is not one of special interest to our readers.

THE CURABILITY OF EARLY PHTHISIS.

At the recent annual meeting of the Liverpool Hospital for Consumption, the resident medical officer of the Kaywood Sanatorium stated that whereas nearly 100 per cent. of quite early cases were restored to complete, or almost complete, health, and of those in the second stage a large number were very greatly improved, only a few of the advanced cases derived more than very temporary benefit, the benefit, as a rule, not extending greatly beyond the period the patient was actually under treatment at the sanatorium.

DR. JOHN A. M. (Ontario).—It will afford us much pleasure to accede to our correspondent's requests.

A SPECTATOR.—For obvious reasons we cannot comment on the case while it is *sub judice*, but we are unable to bring our mind to the idea that a man with such a record can have been guilty of such an inexcusable lapsus.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 28th.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Pathological Evening.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. P. J. Freyer: Clinique. (Surgical.) 5.15 p.m. Lecture: Mr. F. J. Stewart: Bronchocele.

THURSDAY, MARCH 29th.

CHILDHOOD SOCIETY AND THE BRITISH CHILD-STUDY ASSOCIATION (Parkes Museum, Margaret Street, W.).—8 p.m. Lecture:—Mr. E. W. Wallis: Psychology of Reading. (Arranged by the Childhood Society.)

NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8 p.m. Exhibition of Clinical Cases, illustrating various kinds of Ocular Palsies.

ROYAL COLLEGE OF PHYSICIANS OF LONDON (Fall Mall East).—5 p.m. Lumenian Lecture:—Dr. D. Ferrier: On Tabes Dorsalis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutcheson: Clinique. (Surgical.) 5.15 p.m. Lecture:—Dr. T. C. Shaw: The Connexion between Mind and Body.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m. Dr. M. Dockrell: On the Usefulness or Otherwise of the Electrical Methods of Treatment in Skin Diseases. (Chessterfield Lecture.)

FRIDAY, MARCH 30th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Dr. E. Waggett: Clinique. (Throat.)

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m. Papers:—Mr. A. Barker: Treitz's Hernia complicating Gastro-enterostomy.—Mr. P. Paton: A Case of Right Duodenal Hernia in a Child aged Three Months.—Mr. F. Eve: Enormous Cyst of the Common Bile-duct.—Mr. F. C. Wallis: Three Cases of Gastro-jejunostomy.

Vacancies.

Aberdeen City (Fever) Hospital.—Resident Physician. Salary £100 per annum, with board and rooms. Applications to the Medical Officer of Health, 4½ Union Street, Aberdeen.

Charing Cross Hospital.—Resident Medical Officer. Salary £100 per annum. Applications to the Chairman of the Medical Committee.

London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer for the Casuality Department. Salary £100 per annum. Applications to W. M. Wilcox, Secretary.

Egyptian Government.—Kasr-Elainy Hospital.—Resident Surgical Officer. Salary £250 a year, with quarters, servants, washing, coal and light. Applications to the Director-General, Public Health Department, Cairo.

Humberstone Asylum, Leicester.—Second Assistant Medical Officer. Salary £180 per annum, together with furnished quarters and board. Applications to the Medical Superintendent.

Incorporated Dental Hospital of Ireland.—Two Anaesthetists. Immediate applications to W. A. Shea, J.P., Registrar.

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary £100 per annum, with board and lodging. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

London County Asylum, Banstead, Sutton, Surrey.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk of the Asylums' Committee, Asylums' Committee Office, 6 Waterloo Place, S.W.

Oldham Infirmary.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to Rev. Philip Lancashire, Hon. Sec., Oldham Infirmary.

Valkenberg Asylum, near Cape Town.—Assistant Medical Officer. Salary £250 per annum, with board, washing, and lodging. Applications to the Agent-General for the Cape of Good Hope, 10 Victoria Street, London.

Appointments.

BERRY, FREDERICK CHAS, M.D., B.Ch.Dub., Medical Officer of Health of Burnham (Somerset).

BULLRID, ARTHUR, L.R.C.P., and **S. Edin., L.F.P.S.Glaag.,** Medical Officer of Health of Midsomer Norton (Somerset).

BURLAND, CHARLES, M.D.Brux., Medical Officer to the Board of Trade at the Port of Glasgow.

CANN, FRANCIS JOHN HUGHSTREDE, M.B.Lond., L.R.C.P.Lond., M.R.C.S., Admiralty Surgeon and Agent at Dawlish (Devon).

CART, ARTHUR JAMES, L.R.C.P., L.R.C.S., L.M.Irel., Medical Officer for the Bleasdon District by the Axbridge Board of Guardians.

DEAKIN, FRANK N., M.R.C.S., L.R.C.P.Lond., Surgeon to In-patients at the Walsall and District Hospital.

GREEN, J. W., L.R.C.S.Irel., L.K.Q.C.P.Irel., Certifying Surgeon under the Factory and Workshop Act for the Athboy District of the county of Meath.

HARNETT, W. G., M.B., B.Ch., B.A.O.Dub., Senior House Surgeon at the Royal South Hants and Southampton Hospital.

HUTT, C. W., M.R.C.S., L.R.C.P.Lond., Junior House Surgeon at the Royal South Hants and Southampton Hospital.

KEALY, JOHN WILLIAM GREGORY, L.R.C.P.Lond., M.R.C.S., L.S.A., D.P.H.Lond., Surgeon and Admiralty Agent at Priddy's Hard, Portsmouth.

LEGGATT, GERRARD S., M.R.C.S., L.R.C.P.Lond., Clinical Assistant at St. John's Hospital for Diseases of the Skin, Leicester Square.

OLDFIELD, CARLTON, M.D., B.S.Lond., Honorary Assistant Surgeon to the Hospital for Women and Children, Leeds.

POPE, HENRY SHARLAND, M.B., B.C.Cantab., Medical Officer of Health of Bridgwater, and also Certifying Surgeon under the Factory and Workshop Act for the Bridgwater District of the county of Somerset.

Births.

BOWER.—On March 19th, at Redlands, Sutton, Surrey, the wife of George Bower, L.R.O.P., D.P.H., &c., of a daughter.

CARMICHAEL.—On March 26th, at 76 Abnons Road, Cantonments, Bangalore, to Donald Gordon Carmichael, Lieutenant R.A.M.C., and Eileen Mona, his wife, a daughter.

CHAMBERS.—On March 21st, at the Priory, Roehampton, the wife of James Chambers, M.D., of a son.

NUNN.—On March 19th, at the White House, Hadley, Barnet, the wife of J. Wilfrid Nunn, M.R.C.S., L.R.C.P., of a son.

PEPPER.—On March 18th, the wife of Charles Edward Pepper, M.B., Ch.B., of Thornton Heath, Surrey, and Salisbury, Wilts, of a son.

Marriages.

ELLIS—WHEELER.—On March 13th, at St. Jude's Church, Belfast, Henry Reginald Ellis, M.B., West African Medical Staff, second son of W. H. Ellis, of Shipley Hall, Yorkshire, to Isabel, second daughter of C. G. Wheeler, of South Parade, Belfast.

GREAVES—RICE.—On March 20th, at the Church of St. John, Derby, Francis L. A. Greaves, F.R.C.S., elder son of Chas. Augustus Greaves, M.B., L.L.B., to Constance May, elder daughter of George Rice, M.D.

HIGNETT—MAOQ.—On March 22nd, at Childwall Parish Church, Lionel Watson Hignett, M.B., M.R.C.S., to Sarah Bayley (Dolly) Mack.

KAY—LAYER.—On March 20th, at St. Martin's Church, Scarborough, Walter Smith Kay, M.D., Medical Superintendent of the South Yorkshire Asylum, Wadley, Sheffield, to Elizabeth Mary Laver, widow of the late Arthur H. Laver, M.D., of Sheffield.

MCCLURE—BUE.—On March 24th, at St. George's, Hanover Square, James Campbell McClure, M.B., 9 Newton Place, Glasgow, to Louise Marie, younger daughter of the late Jules Bud, M.A. Chevalier de la Legion d'Honneur, Taylorian Lecturer at the University of Oxford.

Deaths.

HARTFORD.—On March 26th, Dora, the beloved wife of H. W. Hartford, M.D., of Christchurch, aged 55.

ROBERTS.—Of typhoid fever, after nine days' illness, John Howard Digby Roberts, M.B., C.M.Edin., of Hope House, Taglar, Morocco.

NOTES AND COMMENTS.

The Central Midwives Board Again.

An unusually lively meeting of this much abused body will be held on Tuesday next for the special purpose of discussing certain questions on which Sir William Sinclair and Mr. Ward Cousins are endeavouring to make the Board register a sensible and business-like opinion. The answer to some of these questions will seem self-evident to our readers, but we fear many members of the Board will not consider them so. Apparently, a discussion will rage for hours round such a question as "Should utterly illiterate women be received as candidates?" Then "How far should any midwife be allowed to use instruments and drugs?" So far as instruments are concerned, it is difficult to see the necessity of this question either. A catheter and an enema syringe are the only "instruments" necessary in cases of natural labour, and to these with the addition of a syphon douche the midwife's instrumental outfit should be confined. The question of drugs perhaps affords a wider field for discussion, though most people will agree that purgatives, perhaps ergot, and alcohol in some form are all that are necessary. The third question to be laid before the Board is a highly important one, "How far should the wrong methods of teaching be allowed to continue without amendment in certain quarters." This is an important and, we fear, a vexed question, but we hope that in it, as in the other two, Sir William Sinclair and his colleague will be able to thrust common-sense into the minds of the remainder of the Board.

An Official Handbook for Midwives.

It appears that there is a desire that the Central Midwives Board should publish an official handbook for midwives. This matter was brought forward by Sir William Sinclair and we regret to have to differ from him upon it. In the first place, what evidence has he for stating that England is greatly behind the times in the matter of handbooks for nurses? We doubt if he will find many to agree with him, even amongst those who differ most widely on other questions. In the next place, who is to write such a book? Is one man to be given the task, and to enjoy a practical monopoly in the sale of handbooks? Are the opinions of one school alone to be represented and those of all others shut out? Even if the Board itself is to receive the profits, under what Act of Parliament is it entitled to become a bookseller and publisher? We believe that such a course would be entirely outside its statutory powers. It is a most invidious thing for a public board to take upon itself the prescribing of special books on which candidates

are to be examined, and for the Central Midwives Board to decide upon a step which would have the effect of killing all existing books on the subject and of preventing competition and improvement, would be a step of which we can hardly believe Sir William would approve. We have no doubt that he has excellent reasons for the suggestion he has thrown out, but they seem to us to be based on false premises.

Babes and Sucklings.

The vagaries of educational bodies are endless. Some of them engage our sympathy, even when they do not always appeal to our judgment. Others, again, demand our unqualified disapproval. Among the latter is the entrusting to small children dangerous drugs by way of chemical investigation. That particular phase of modern schoolcraft resulted in the death of an unfortunate little girl a few weeks ago at Plymouth. She was given a pipette to fill with dilute alkali for the purpose of neutralising an acid solution. By error she drew into her mouth a strong solution of caustic alkali, which she swallowed. She refused the antidotes offered by the teacher, and subsequently died. This sort of transcendental teaching is calculated to bring ridicule upon our education authorities. If the spirit of the kindergarten is to dominate our elementary schools, at least let us keep deadly drugs out of the hands of babes and sucklings.

Hospital "Scandal" at Hastings.

THERE is nothing dearer to the average journalist than a "hospital scandal." An affair of that sort goes deep down into the heart of things, and furnishes a fine field for sensational copy, not to mention strong and lurid headlines. But there is no smoke without fire, and in spite of every sympathy with the magnificent voluntary medical charities of the United Kingdom, it must nevertheless be confessed that, on the whole, newspaper criticism is not only a salutary but also a desirable and necessary discipline. In the case of a recent outcry at Hastings it must be admitted that some of the bearings of the case demand careful consideration at the hands of our profession. The facts, are, briefly, that a man, aged 31, was recently admitted to the East Sussex Hospital one afternoon. A few hours afterwards he was found to be suffering from acute erysipelas, and at half-past eight on the same evening, on a cold night, he was removed to the workhouse infirmary, where he shortly afterwards died. The removal was effected by the directions of the surgeon for the week, and there appears no doubt that it was done on account of the infectious nature of the complaint.

Was there a Scandal?

It may be fairly assumed that death, if not directly due to the removal, may have been accelerated thereby. Without going into that part of the case, of which the medical men in attendance are the only competent judges, we are entitled to ask if such a removal was absolutely necessary, and, if so, on what grounds? Therein lies the "scandal." Now, as we all know, erysipelas is only feebly contagious, and many persons scoff at its being included in the Local Government Board list of notifiable maladies. In the old days it was one of the grim terrors of that devastating scourge, hospitalism. Nowadays, erysipelas has been robbed of its sting. The streptococcus of erysipelas is no more dangerous in the wards of a well-ordered hospital than the staphylococcus or bacillus coli or any other pyogenic organisms. Listerism has seen to that. By all means exclude an erysipelatous patient, but there is no overwhelming need, so far as we can see, to turn out a patient who is found to be suffering from the malady.

Where was the Isolation Ward?

Has the East Sussex Hospital no isolation ward where this unlucky patient could have been placed instead of turning him out in a dying condition upon a freezing night? We are inclined to think there is some sort of a scandal here. Not much argument is needed to support the contention that every hospital admitting in-patients should be provided with an isolation ward. Infection is round us everywhere; no man knows when it may come upon him. If the East Surrey Hospital be so doubtful of its methods that it fears the spread of erysipelas to its surgical cases, then the need of an isolation ward is more than self-apparent. It is to be hoped that the good folk of Hastings will not miss the moral of this unhappy incident, and will insist that their otherwise excellent hospital be at once provided with ample isolation accommodation. If funds are available the simplest plan would be to secure a house for the purpose in the immediate vicinity.

LEADING ARTICLE.**THE TREATMENT OF CRIME.**

READERS of the daily press may have noticed that a new movement is taking place with regard to the treatment of certain criminals; indeed, in some quarters a note of alarm has already been struck at the innovation. Within the last few weeks two women undergoing penal servitude for murder have been released and committed, under certain conditions, to the care of the Salvation Army. It is understood that in these cases the Home Office took the initiative and asked the Salvation Army authorities if they were prepared to make the charge of these wretched women their special care, so that it may reasonably be assumed that at last a spirit of enlightenment and humanity has penetrated the rusted bars of our prison-cells, and that in the future one may look for a development of a policy which promises to place this country in the front rank of nations for the scientific treatment of depraved humanity. Moreover, as these conditional releases coincide with the advent of Mr. Herbert Gladstone at the

Home Office, it may be taken for granted that it is his lead in this matter which has brought these results about, and we venture heartily to congratulate him on his courage in starting so early in his administration an experiment which is likely to be fraught with momentous consequences. So far we have spoken only of the change in prison policy, for it is this change from the stupid or vindictive to the reasoned and humane which is the striking feature, but we must not overlook the method by which the practice is being accomplished. These prisoners, the first-fruits presumably of a numerous detachment, are being placed under the care and authority of the Salvation Army, a body primarily religious and secondarily philanthropic, privately managed and autocratically controlled. With every desire to speak fairly of the great social work that the Salvation Army has performed, work which has gained it wide respect in spite of its "corybantic Christianity," we hope that the merits and demerits of committing State prisoners to their charge will be carefully weighed and watched. Medical opinion with regard to the treatment of criminals is far in advance of that entertained by lawyers or other classes of men; first, because the medical man has constant opportunities of watching the inmost workings of the mind of men in all ranks of life, and secondly because he knows that persons who commit anti-social acts do so from motives and impulses as varied as their mental constitutions. It cannot fairly be said that medical opinion is totally opposed to severity; it is only opposed to stupidly-conceived and maladroitly-applied severity; severity, in fact, which by over-reaching itself neither deters the victim from repeating his fault nor presents to him better motives upon which to act in the future. Severity is the last resource, the power behind the Throne, and should be reserved for the malicious and dangerous characters, who are at the same time mentally sound and morally incorrigible. But this class will be found to shrink in dimensions as scientific methods of punishment, which are practical methods of reclamation, are pursued. The mode in fact to be pursued is that of making the punishment fit not the crime, but the criminal, and we maintain that as the criminal is a mental patient the proper person to carry out his regimen is not the super-annuated major who wants supplement to his retired pay, but the experienced doctor, who has studied the functions of the mind and body. Now, in so far as the Home Office policy marks a departure from old-time methods it is sincerely to be welcomed, especially as it gives evidence of the confidence engendered in moral management, such as has been exploited for the last few years at Borstal, where juvenile and adult prisoners have been trained into useful citizens instead of being buffeted into confirmed criminals. But it is a question of high policy whether the State is justified in ridding itself in any degree of the responsibility for the managing its own prisoners. Persons when condemned to gaol are the charges

of the State, and it is the duty of its officers to devise a system by which they may be returned to society purged of their vicious tendencies, or else maintained in a humane isolation where they may be as little noxious as may be to themselves and each other. It may well happen that voluntary agencies of trustworthy character form the best link between prison and honest employment, but the prison-system itself should be so designed that their aid is only invoked when the probationary period is past. There are many indications—among others these very acts of the Home Secretary—that steady and even revolutionary changes are taking place within prison-walls, changes dictated by an appreciation of the relative values of the mental and moral elements in crime, and making for the regeneration instead of the degeneration of the prisoner. It is to the expansion of these changes that we look for safety and reform rather than to the extension of responsibility from the prison to the voluntary agency, and we hope, not without good grounds, that we may eventually see first a plan of classification constructed according to the principles of morbid psychology, and secondly an educational ladder provided whereby the reclaimable may mount, from the time of commitment to the time of discharge, till they emerge on a moral par with their fellows. Not the least difficulty that prison authorities have to contend with is the attitude of the judges, who in the main are out of touch with modern criminology, but there are some at least who are amenable to medico-legal teachings, and these may in time leaven the whole bunch.

NOTES ON CURRENT TOPICS.

Sale of Poisons.

THE regulation of the sale of poisons is a matter of such importance that no good citizen should endeavour, from motives of self-interest or profit, to put any obstacle in the way of a stringent safeguarding of the general public. For some time past the chemists have been agitating to have the provisions of the Pharmacy Act of 1868 put into operation against agricultural agents, nurserymen and others who sell such poisonous preparations as insecticides, sheep dips, and weed killers, and last week Lord Crewe introduced a Bill into the House of Lords a clause of which provides that the local authorities may license such persons as they think fit to trade in these poisons. This is a distinctly retrograde step, though it is being hailed with joy in many agricultural circles. It is claimed as a great convenience that such goods can be obtained from various agencies instead of only from registered chemists, and the manufacturers of these articles maintain that their trade can be better pushed by means of florists, nurserymen and similar dealers than by pure pharmacists. Such no doubt is the case, but it is this very facility for obtaining poisons that lends itself to abuse, and we would earnestly appeal to right-minded people

to consider whether a little personal sacrifice which makes crime and suicide more difficult of accomplishment is not well worth the making. After all, if the profit on sheep dips and insecticides goes to the chemists, they are the people who, from their training and responsibilities, are morally entitled to it.

Vaccination of Teachers.

FROM a statement made by Mr. Birrell in the House of Commons last week it is not unfair to hazard a guess that an important change in vaccination policy is likely to occur. The Minister for Education was asked by Mr. MacDonald, the Labour member for Leicester, whether he had received an application from the Leicester Education Committee asking that teachers might be excused from being vaccinated against their will, and whether the conscientious-objector clause could not be extended to such teachers. In his reply, Mr. Birrell said that vaccination had always been made a condition of a teacher's appointment under the Education Board, but that in certain districts this provision made it difficult to obtain an adequate supply of candidates. Moreover, he proposed to consider whether it might not be possible to throw the onus of insisting on a relaxing of the vaccination provisions on the local authorities, but that he was not prepared to make a definite statement yet. His decision will be awaited with interest by the medical profession, for it will mark an epoch in the history of vaccination. It has always been held by Parliament that insistence on vaccination was a matter of high policy that could not be delegated to local authorities to decide, because the question of immunity concerned the country as a whole. The vaccination officer is directly under the Local Government Board as regards the enforcement of the Acts, and the Board have insisted in his prosecuting defaulters, even in defiance of local opinion. If Mr. Birrell decides to remit the vaccination of teachers to the local authority it will be impossible for other Government departments logically to insist on keeping vaccination in their own hands, and if this become so the Acts will not be worth the trouble their administration will cause.

Vivisection Inquiry.

THE Home Secretary has announced that he proposes at an early date to institute an inquiry into the Experiments on Animals Act and the regulations under it, but that he has not yet decided on what form the inquiry shall take. No scientific or medical man will be prepared to take exception to such a step. It is now over thirty years since the Act was passed and public opinion has been a good deal agitated ever since, mostly through the instrumentality of foolish and unscrupulous people. As scientific investigators have always claimed that there is no abuse of the powers granted them, and as no single case of cruelty has ever been proved, in spite of the shower of reckless statements made by the anti-vivisectionists, experimenters have nothing to lose

and everything to gain by an open and fairly constituted inquiry. Needless to say, Mr. Stephen Coleridge is to the fore at this juncture, and he writes to the *Daily News* of March 28th, saying that he and his supporters object to vivisection—"the infliction of torment upon animals," as he calls it—on moral grounds, quite irrespective of the effect of experiments on the ascertainment of scientific truths. Anti-vivisectionists generally find any stick good enough to beat their favourite dog with, and for a long time they have tried to convince scientific men that they know more about their business than these do themselves. In face of constantly-accumulating evidence that much sound and useful knowledge is derived from experimentation, they have apparently dropped that claim, and Mr. Coleridge now wants an inquiry directed "to the moral rather than the scientific aspect of vivisection." The idea of a Royal Commission inquiring into morality is a novel one; that question is usually left to the individual conscience; but, if appointed, we trust the report will have an educational value in helping people to arrive at a just conclusion.

Face Massage for Men.

VAIN and silly women have not hesitated to open their purses to the gang of face specialists and beauty-restorers who delude them with hopes of removing wrinkles and rejuvenating complexions that are seared by the hand of Time. A similar trap, we understand, is now being laid for the peacocks of fashion who combine the form of men with the attributes of the least desirable women. A further bait is offered by the announcement that face massage brings alertness and brightness to the mind, and that the mental faculties are increased in acuity by the practice. What is certainly true is that the class of person who believes such twaddle needs a good deal more mental alertness than he is likely to get from face massage or any other process that we are acquainted with, and that the "mug-catchers" who batten on such deception should receive their deserts. If we had not actually read the facts on which our comments are grounded in a leading daily contemporary, we should have thought we were being hoaxed by some clumsy practical joke.

The "Register," for 1906.

THE appearance of this official volume serves as a reminder of the lapse of another year. On opening its pages we are at once faced with the "important notice" that every registered medical practitioner should notify to the Branch Registrar by whom he was originally registered any change in address or in qualification. The neglect of this simple precaution is shown by the many addresses missing in the medical directories—as apart from the *Medical Register*, from which names of defaulters are expunged. The total number of medical men in register on December 31st, 1905, was 39,060, which shows an increase upon the average for the past five years—namely, 37,915. The radical defect in the British system of medical

registration, in our opinion, lies in the fact that registration is not compulsory. There is the usual mass of interesting and valuable information in the preface, such as a summary of the Medical and other Acts relating to the Medical profession. The volume is cheap, accurate, and comprehensive, that is to say, so far as its constitution permits it to comprehend.

The British Medical Association and its Charter.

FOR some time past the British Medical Association has had in contemplation the advisability of petitioning the Crown for a charter. What the precise advantages to be gained by the possession of a Charter may be we are not prepared to say, and apparently the members of the Association were also very much in the dark, since with a recent number of the *Journal* it was necessary to distribute a Supplement of some five-and-thirty pages dealing with the matter. But knowledge on the various points *pro* and *contra* seems to have been regarded as a minor consideration, since the representative Meeting at Leicester had already given the Central Council power to apply to the Privy Council for a Royal Charter. At the same time, however, the Council was directed to furnish the Divisions with an estimate of the probable expense. It appears that, up to the present, inquiries and preliminary investigations have cost £390, and it is forecasted that the cost of completing the application, if no opposition be offered, will be about £630. In cases of serious opposition it is impossible to estimate probable expenses. We understand that the principal advantage expected from the possession of a charter is freedom from the restrictions of company law. It is to be remembered, however, that these restrictions are for the most part imposed for the protection of the individual members or of a minority of the company or association, and it is a serious matter for the members to decide whether the problematical advantages of a charter counterbalance a possible usurpation of powers by a dominant majority.

The "Dr." Muschik Prosecution.

IN our issue of March 21st we commented on the successful prosecution of an electrical quack, who carried on an extensive practice in London, near the Marble Arch, and at other addresses. That notice spoke of the Medical Defence Union, by whom the action was instituted, as deserving the undying gratitude of the medical profession. In further comment, however, we regret to say that a ridiculous blunder was committed. The name of the quack Muschik was confused with that of the nominal prosecutor, Mr. Thomas William Tyrrell, clerk to Mr. W. E. Hempton, of King Street, Cheapside, E.C., the well-known solicitor to the Medical Defence Union. The latter gentleman has now secured many convictions against unqualified medical pretenders in the Metropolis. In nearly every one of them Mr.

T. W. Tyrrell has figured as what may be termed the stock patient! He deserves the gratitude of our profession, therefore, for the solid services he has rendered towards the consolidating and upholding of legitimate medical practice. Fortunately his name has become so closely associated with Defence Union proceedings that the confusion of his identity would in all probability be instantly detected by the majority of our readers. On inquiry, we find that the error was due to the serious illness of a valued and usually accurate contributor.

Greek at Cambridge.

WE are very glad to see that the friends of scientific education at Cambridge are returning to the charge after their recent defeat on the question of compulsory Greek. The University have now admitted the principle that a man may be eligible for Academic honours without possessing a knowledge of Greek by excusing certain Oriental students from presenting that language in the "Little go," on condition they take Sanscrit or Arabic in its place. The scientific men naturally ask why, if this class of students is excused the old-fashioned restriction, their own pupils should not be similarly treated. The present proposal of the Syndicate is that the B.A. degree should be given under two designations, "Bachelor of Arts in Letters," and "Bachelor of Arts in Science," and that whereas Greek should remain compulsory for the former, it should not be for the latter. We think it would be simpler to propose that two separate degrees, B.A. and B.Sc., should be given, and while candidates for the former should be compelled to take Greek in their previous examination those for the latter should present a modern equivalent if they desire. Anything which would break down the antiquated practice of the University in this respect would be greatly welcomed, for, with its busy, pushing, scientific school, Cambridge should be able to attract the best intellects in the country, were the present silly restriction removed. We have more hope of Cambridge giving way than Oxford, where mediæval dons still demonstrate their accomplishments in the humanities by strictly keeping out of touch with the realities of the outside world.

OUR WEEKLY PILLORY.

UNDER the heading of "Our Weekly Pillory" we propose in each issue to notice objectionable quick advertisements appearing in lay newspapers. To-day we take *Reynolds' Newspaper*, Sunday, April 1st, 1906. We find on page 9 a "cure for blindness" described as a new and marvellous discovery, and the guaranteed greatest remedy on earth. The address given is Leggett, Wisbeach. It seems hardly necessary to inform the Editor of *Reynolds'* that an advertisement of this kind represents the highest pitch of audacious and heartless quackery. As a barrister and an educated man of the world, the gentleman in question must be aware that the overwhelming majority of cases

of blindness are hopelessly incurable, and that of the remainder a small proportion may be saved by skilled surgical operation, and by that alone. Hence in taking money for the advertisement quoted he is assisting in the publication of a gross fraud upon the public. There are many other objectionable advertisements in the same issue of his journal. The only one we shall now mention is a wonderful remedy "to cure drunkards with or without their knowledge," advertised by the Ward Chemical Company, Regent Street, London. No such remedy is known to medical science, nor is such a remedy conceivable. Here again the Editor is assisting in another sham. As his paper advocates high and advanced ideals in social matters, it will be well if he sets his own house in order with regard to frauds perpetuated at the cost of the welfare of the poor, the weak-minded, the ignorant, and the suffering of our community.

PERSONAL.

WE are glad to note that Dr. Robt. A. Slessor, of Fraserburgh, has won the case brought against him by a chemist of the same town for alleged slander, and has been awarded costs in the action.

At a special meeting of the management of the Cardiff Infirmary, Dr. Paterson was appointed honorary surgeon to the ear, throat and nose department, and Miss Erie Evans, M.B., was elected to the post of honorary assistant physician.

FIELD-MARSHALL LORD ROBERTS presided yesterday at the festival dinner of the Ventnor Royal National Hospital for Consumption, held at the Hotel Métropole, London.

THE British Government is to be represented at the forthcoming Lisbon International Medical Congress by Colonel A. T. Sloggett, R.A.M.C.

MR. O'BRIEN FURLONG presided over the recent meeting of the supporters of the Royal National Hospital for Consumption for Ireland, among whom were His Excellency the Lord Lieutenant of Ireland and the Countess of Aberdeen.

PROFESSOR ANNANDALE was last week entertained at the first annual dinner of the Sheffield Edinburgh University Club, under the presidency of Dr. J. H. Keeling, the doyen of the Medical Profession in Sheffield.

A SCOTTISH Association of Medical Women has been formed under the presidency of Miss Emily Thomson. The Honorary Secretary is Mrs. Chalmers Watson.

A FUND is being collected to erect a monument to the late Professor Nothnagel, of Vienna, and to found a lectureship bearing his name.

WE regret to have to announce the death, at the Westminster Hospital, on April 1st, from septic poisoning, the result of a *post-mortem* wound, of Mr. R. Newman, a distinguished student and the editor of the *Broadway*.

A CLINICAL LECTURE

ON

CANCER OF THE UTERUS.

Delivered at the Royal Southern Hospital, Liverpool.

By WILLIAM ALEXANDER, M.D., F.R.C.S.I.,

Surgeon to the Hospital, and Lecturer on Clinical Surgery, University of Liverpool.

GENTLEMEN,—According to the returns of the Registrar-General, cancer of the uterus accounted for 3,869 deaths in the year 1902. Like cancer elsewhere, it is a fatal disease that kills its victims within one to two years of its onset, and attacks both married and single women from the age of 45 years and onwards. It occasionally occurs early in life. I have met with a case of carcinoma uteri in a patient, *æt.* 26, and there are other cases on record of early recurrence. These are interesting from their rarity, but are only exceptions that prove the rule that carcinoma is a disease of mature age. This is a point I wish you to remember, as we are building an important superstructure upon it which will be submitted for your consideration before the end of this lecture.

If we look at the uteri removed at my operations, or at their photographs, which I now show you, it will be seen that 28 are examples of epithelioma of cervix, and 13 of the body of the uterus. In all these 28 an irregular mass of newly-formed tissue grew from the cervix, variable in extent, sometimes sufficient to fill up the vagina, at others more moderate in size. The growths were soft, friable, bled readily when touched, and were generally accompanied by a profuse vaginal discharge that was often foul, sanguineous, and distressing to the patient. The uterus was movable in all the cases under consideration, and no pelvic glands could be felt, but I need not tell you that they were all early cases, and that the majority of cases you will meet with in practice will be quite different, except you are on the *qui vive* for early cases. For instance, during the six years ending December 31st, 1901, 98 cases of cancer uteri were admitted into the surgical wards of the Liverpool Workhouse Hospital with the uterus more or less fixed, and sometimes to the examining finger quite immovable, and with the pelvis filled with a hard, malignant mass. In other cases, deep ulcerating cavities existed with openings into neighbouring viscera, and where exhausting discharges and hæmorrhages soon destroyed the patients. It is rare to find an operable case admitted into the Workhouse Hospital, as pauper patients have great endurance, and think all ailments trivial until death stares them in the face. In some of these 41 operable cases, the vaginal wall was encroached upon, but never to any great extent. The diagnosis of such cases of epithelial cancer of the cervix is easy, and the attention of the patient is always called early to its presence. If a surgeon were immediately consulted when a patient first knows that she has something wrong with her uterus, not much time would be lost before the question of operation could be considered, but many patients put off such a course as long as possible, partly through feelings of delicacy, and partly in the mistaken belief that the symptoms indicate the condition popularly known as "the change of life," or "the whites." When the discharge is coloured, they incline to the "change of life" theory, when pale to the theory of "whites." Their confidants share with them the belief in such a diagnosis, and by so doing comfort the sufferer greatly, especially those who in their heart of hearts have a suspicion that they may be suffering from cancer, and who refuse examination lest the secret dread might be converted into a declared reality. I have been consulted by ladies suffering from internal polypi or simple erosions, who for a long time resisted all the efforts of relatives to induce them to see a surgeon. When at last they consented, and after examination they were told that

the disease was simple and not malignant, the mental relief was so great that they became almost intoxicated with joy. Such cases showed by the extent of the recoil the tremendous strain they must have endured in secret for a long time. It is only by education that such obstacles as are placed in our way by the patient can be overcome. As soon as she permits an examination, the epitheliomatous growths of the cervix are immediately recognised by their feel, their tendency to bleed, and their appearance, and if necessary a piece can be easily obtained for microscopical examination.

Early access to the disease is the *desideratum* in these cases, and the doctor called in to a patient complaining of uterine discharge should always advise a thorough examination, and should not depend on giving in a casual manner ergot internally and perchloride of mercury or other douches, as is too often the practice. Both the ergot and the douche relieve the symptoms for a time, but they only temporise with the disease until the period of local development, during which we can perform operations, has passed by, and the disease has gone beyond the limited area that we can deal with by operation. The other varieties of cancer of the body of the uterus, such as malignant adenoma, scirrhous and alveolar carcinoma, specimens and sections of which are on the table, are much more stealthy in their onset, and more difficult to diagnose. Fortunately, they do not spread to the lymphatics so rapidly as do the cervical cancers, so that we have more time to make up our minds. The uterus enlarges, the cervix may have become hard and stony in character. Hæmorrhages and unpleasant discharges may appear, and are early characteristics. The patient early exhibits signs of failing health, such as pallor and general feebleness, too indefinite to be noticed except by the eye of anxious friends or of an experienced family medical attendant of long standing. Curettings do not assist much in clearing up suspicions, indeed they often lead us astray by their negative evidence. There are no more difficult cases upon which we have to decide than these obscure cases of cancer of the body of the uterus. Failing health, hæmorrhages and discharges are the most common symptoms. The decision must, if possible, be made soon. The old plan of waiting for some decisive evidence to turn up should be abandoned, as probably by the time the case clears itself up an operation will be out of the question. All the evidence has to be carefully weighed, and microscopic evidence obtained if possible. If this is positive it is most satisfactory, but if negative is not of much value as compared with clinical evidence upon which most surgeons place the greater confidence. After operation the microscope is of great value, and to its bar the uteri removed on clinical evidence alone have to be brought for final decision. In many of my cases, the operation was performed on clinical evidence alone, but the post-operation classification was made only on microscopic evidence. Except in two cases of hæmorrhagic adenomatous growth, which we do not think now were microscopically malignant, in all the other cases the microscope supported the clinical diagnosis of malignancy. This photograph shows a case where the disease affected the mucous membrane only, and where the microscope showed a malignant adenoma, but Dr. Dimond, our pathologist, will show you the sections, and you will be able to study for yourselves the histological features of these morbid growths.

The questions I wish to bring before you to-day are practical questions. You all know that one character of malignancy in a cancerous growth is the tendency to recurrence after removal. Cancer of the uterus is no exception in this respect. Indeed, what with the difficulty of gaining early access to the disease through the reticence of the patient, in some cases to the difficulty of diagnosis, the results of hysterectomy, that is, the removal of the disease and with it the entire uterus, are still far from being as good and permanent as we may in the future expect. The operations performed at the present day are either vaginal hysterectomy or abdominal hysterectomy, and about these I will have a word to say afterwards. We will first of all refer to the results of operation.

In the *Journal of the British Gynecological Society* for May, 1905, Dr. Jacobs, of Brussels, an expert operator, gave the results of his operations for cancer of the uterus. In 80 cases of vaginal hysterectomy which he examined, 10 cases were lost sight of. In the remaining 70, 49 recurred within a year, 9 within 2 years, 11 within 3 years, and 1 within 4 years. Not one of the patients was alive four years after the operation. After such results he abandoned vaginal hysterectomy and adopted abdominal hysterectomy, in which operation after removing the uterus he cut out as much as possible "of the infected pelvic lymphatic territory." The results were that out of 89 cases of these extensive operations at the time he read his paper, 87 had died, 2 only were still alive and supposed to be cured. During the first year there were 40 recurrences, second year 20 recurrences, third year 4, fourth year 2, fifth year 2, sixth year 1. If Professor Jacobs' results are usual, the operation of vaginal hysterectomy should be abandoned, as they are not such as to justify the performance of a serious operation when we know that in a year or two recurrence will take place, and that all the misery will have again to be endured without hope of any relief. The abdominal operation, with its larger operative mortality, and only two women alive and supposed to be cured out of 89, does not encourage us, although, urged on by such miserable results as vaginal hysterectomy gives, many surgeons are now trying the abdominal operation. We can never desist from attempting relief, *in some way*, as it is only by perseverance we can hope finally to overcome the disease. Dr. Jessett at the same meeting gave the results in 170 cases who survived operation—35 had recurrence and died within the year, 23 cases died at intervals of 2 to 4 years, 8 are alive at periods varying from 5 to 13 years. Three cases were known to have died from other diseases, and had no recurrence, whilst 20 were lost sight of.

When I saw Dr. Jacobs' paper in print, I began to inquire about my past operations to ascertain if I was equally unfortunate in my permanent successes. The number of my cases of vaginal hysterectomy is small compared with that of pure specialists. I have only been able to unearth 41 consecutive cases who survived operation during the past ten years. Three died from the operations, or soon after, making about 7½ per cent. mortality, but the deaths mostly occurred among my earlier cases, some of which were too advanced for safety. Of the 41 cases, 16 up to the present cannot be found, although I am still hopeful of being able to complete the after history of many of these by further inquiries. Of those whose history can be followed, 16 are alive and well when seen—4 after a year, 5 after 2 years, 2 after 3 years, and 3 after 5 years, and 1 after 10 years. Another case I operated on six months ago is well so far. Of the 9 who died, 1 case died six months after operation, 4 died 18 months after operation, 2 died two years after operation, 1 died four years after, and 1 died five years after. Of course, time will sift these cases still further, but at present I think I am justified in continuing vaginal hysterectomy in suitable cases. I am very pleased at this, because vaginal hysterectomy is an operation that with practice becomes easy of performance, is safe for the patients, and leaves no external scar or

tendency to hernia. Earlier operation, not more extensive ones, should be our motto.

I now wish to call your attention to the method of operation that I carry out under the term vaginal hysterectomy, for there are several methods of performing the operation. No two surgeons operate exactly alike, and the method may influence the ultimate results. First, I cleanse the cervix as far as practicable, clearing away soft foul tissue, and making the vagina and vaginal cervix as clean as possible. A duck-bill speculum is now placed in the vagina and the uterus is brought down into the field by a vulsellum that grasps the cervix. The mucous membrane is now incised quite round the cervix and well clear of the disease, next the mucous membrane and bladder are separated from the anterior wall of the uterus, the friction of a piece of gauze being most effectual in completing the separation. When the peritoneum is in sight, and the bladder quite freed, not only in the middle line but at the sides, the most delicate part of the operation is over, as the bladder and ureters are the structures to be carefully respected. I now turn my attention to Douglas's pouch, which is easily opened right across by a few snips with scissors. A long piece of sterilised gauze is pushed into the pelvis to keep it free from infection. With a finger in the pelvis, through the opening, and an assistant keeping the bladder, ureters, &c., well out of the way outside, the lower part of the broad ligament of the left side is made prominent, by the finger behind, and a clamp is placed on it well outside any diseased tissue for about two inches. The right side is treated in the same way. Then by cutting the tissues on the distal sides of the two clamps, the cervix is released from its fixed condition below. The uterus is now freely movable, and can be easily pulled down and the peritoneum opened, until the fundus appears outside and the appendages can be reached and dealt with. You will have seen that I always use clamps. Clamps can be applied much more rapidly, and what is of more importance, much more widely than ligatures. The hæmostasis is more certain and the disease can be more widely removed. The piece of gauze in the pelvis is now withdrawn, the opening is packed with sterilised gauze, the speculum removed and the patient put to bed. The urine is drawn off every eight hours. The clamps alone are removed in 48 hours, and on the third day the vaginal packs are removed. Some sloughing of the clamped margins occurs, and we may regret the clean convalescence after the use of ligatures. But the greater freedom of removal easily counterbalances the æsthetic advantages, and I think my results justify the method of operation. I have not performed abdominal hysterectomy for cancer with removal of affected lymphatics. When I have reason to think that better results can be obtained in that way, I will adopt it.

You will have noticed, gentlemen, that before and after operation I administer to my patients dilute hydrochloric acid in as large doses as they can take without inconvenience. The grounds upon which I administer this drug are these:—First, as Professor Moore, Professor of Bio-Chemistry, has shown—largely by examination of test meals taken from the stomach of my cancer patients, by Dr. Kelly, one of the Alexandra Fellows at the Liverpool University—*there is a diminution, often an absence, of free hydrochloric acid in the stomach of cancer patients, no matter in what part of the body the cancer is situated.* I asked you to remember early in the lecture that cancer is a disease of mature age, when we know that many changes in the different systems of the body occur, and perhaps among these changes we may suppose a tendency to alkalinity in the tissues, either more so in some individuals, or to some extent in all people as they grow old, but the conditions have not yet been worked out among healthy people. Owing to this change in chemical reaction of the tissues, a rapid proliferation of epithelium, that was hitherto kept within bounds by a more acid state of the medium in which the epithelial cells lie, now takes place, and is promoted by the change from acid to alkaline surroundings, as Professor Moore

has shown from his experiments on the eggs of the sea urchin. Therefore if we can render the tissues of a cancer patient more acid, we can retard the growth of cancer; although we cannot hope to remove the elements of the cancer masses that have already been formed. By the administration of dilute hydrochloric acid in maximum doses cancerous tumours seem to us to become more movable, and more capable of removal by the knife, and when once the mass of disease has been removed we may hope by persevering with acid treatment, that weak colonies of cancer cells that hitherto, after escaping the knife grew strong and became prominent recurrent tumours in one to four years after operation, may instead wither away and hence recurrence may become a more and more rare result of operation for cancer. I hope to bring before you the clinical evidence favourable to this view in an early lecture, but whether there is anything in the idea or not, the drug is cheap and wholesome, and until we have proved or disproved the theory we may as well give every cancer patient the benefit of the doubt.

NOTE.—A clinical Lecture by a well-known teacher appears in each number of the journal. The lecture in next week's will be by William S. Haughton, M.D., B.Ch., visiting Surgeon to Steeven's Hospital, Dublin, "On Fractures of the Shaft of the Femur."

ORIGINAL PAPERS.

CHRONIC DIARRHŒA.*

By ROBERT HUTCHISON, M.D., F.R.C.P.,

Assistant Physician to the London Hospital, and to the Hospital for Sick Children, Great Ormond Street.

MR. PRESIDENT AND GENTLEMEN,—I admit that the subject of chronic diarrhœa is not at first sight an attractive one. It fulfils, however, the conditions which are likely to lead to a good discussion, for it is a common condition, and one of which we have all had experience. Further, I hope to show that it is not so devoid of scientific interest as might be supposed. It is a disorder, too, which lends itself very well to treatment and for which patients urgently seek our aid, realising as they do, with an eminent physician and philosopher, that "people who have relaxed bowels have seldom strong thoughts, or strong bodies."

Now the first thing for us all to realise thoroughly about our subject is, that frequent action of the bowels, like frequency in micturition, is not a disease in itself but a symptom of some disorder in the alimentary tract, which disorder it is our business to detect and to remedy, if we can. I should, perhaps, apologise for putting this very obvious consideration before you, but I cannot help thinking that such a caution is needed, for in the rush and hurry of daily practice we are all apt to be tempted to regard chronic diarrhœa, when occurring in an otherwise apparently healthy person, as simply a disease in itself and to treat it by one or other of the recognised "astringent" drugs. That such practice is sometimes successful I do not deny, but that it is often bound to fail is equally indubitable, for in the long run the only satisfactory way of removing a symptom is to strike at its cause, and chronic diarrhœa is a symptom which may result from many different causes, each requiring appropriate remedies. I purpose, therefore, in this paper to consider one by one the different morbid conditions in the

alimentary canal which are capable of causing chronic diarrhœa and to point out how they may be dealt with.

OBSTRUCTIVE DIARRHŒA.

In the first place it may be well to remind ourselves that chronic diarrhœa is sometimes the result not of a too free action of the bowels but of their obstruction. This is impressed upon all of us, I think, from our earliest student days, but still it is apt to be forgotten. I was asked not long ago, for instance, to give advice regarding the dieting of a woman who had suffered from diarrhœa for some months. On inspection, the abdomen was found to be rather distended, and on examination by the rectum a large malignant growth was felt not very high up. One does not like to make such a mistake as that. It is well to remember, too, that malignant disease of the rectum or sigmoid may cause chronic diarrhœa even in the absence of any actual obstruction. The following are illustrative cases :—

A woman, æt. 51, came under my care at the London Hospital in September, 1904, complaining of diarrhœa of one year's duration. Her attack—and this is the misleading point in the history—had started with acute purging and vomiting after eating some fish, and the alvine discharges had continued since. She had seven to eight motions daily which were sometimes fermenting, sometimes contained slime and blood. She had lost upwards of one stone in weight. On examination she proved to be moderately wasted and an apparent thickening of the transverse and descending colon could be made out. Nothing was felt by a finger in the rectum. I believed her to be the subject of ulcerative colitis, an opinion in which one of my surgical colleagues who saw her with me agreed, but at the exploratory operation which was undertaken a large malignant growth was found in the upper part of the rectum.

A lady æt. 51, had suffered from diarrhœa for two years, but without any marked loss of flesh or strength. The number of actions fluctuated greatly from day to day, but were often as many as eight. They were mostly passed in the night and were often attended by pain, and had sometimes contained dark blood and visible mucus, but more often were abundant and light coloured. Examination showed no sign of cachexia, and abdominal palpation revealed nothing. A finger in the rectum could just reach the edge of an ulcer, which did not seem indurated, and from which there was no malignant fœtor. Subsequent examination under an anæsthetic with the sigmoidoscope, however, showed that the ulcer was undoubtedly malignant.

Cases such as these might deceive the very elect, but in order to avoid being led into error by them one should remember the old admonition: Put your finger in the rectum and you will never put your foot in it. Better still in these later days use the sigmoidoscope. By its aid the nature of the second of the above cases was made clear, and doubtless it would have done the same for the first also had it been employed.

ULCERATIVE COLITIS.

Another condition of the large bowel which may give rise to chronic diarrhœa is ulcerative colitis. Sometimes this is the result of chronic dysentery, as in the following case :—

Wm. M., æt. 30, a sailor, had suffered from diarrhœa with blood and slime in the motions for seven months. He had been abroad a good deal, and ten months previously had an attack of dysentery. The motions were unformed, most of them containing visible mucus, and some of them blood. He was rather thin and sallow, but the abdominal examination was negative. Per rectum the mucous membrane felt roughened and ulcerated. A cæcal fistula was established, and the

* A Paper read before the Kensington Division of the British Medical Association, March 27th, 1906.

colon irrigated daily with a solution of nitrate of silver (18 per cent.). Under this treatment the condition of the stools improved greatly, but he finally developed symptoms of abscess of the liver, from which he died three months after he first came under observation. At the autopsy the colon contained a few unhealed dysenteric ulcers and the scars of a great many others, which had apparently healed under treatment.

Sometimes the ulceration is not of dysenteric origin, as in the following case:—

Chas. P., æt. 44, a farm labourer, was sent to hospital in January, 1904, for "proctitis." Four years before he began to suffer from a discharge of blood-stained mucus from the rectum. He was at that time troubled with constipation. Lately, however, he has had morning diarrhoea, four or five motions coming in rapid succession. He was a well-nourished, healthy-looking man. On abdominal palpation nothing could be made out except some thickening of the sigmoid. Examination with the sigmoidoscope showed extensive superficial ulceration of the mucous membrane as far as it could be inspected. The stools were putty-like and contained visible mucus and some blood. On January 24th, Mr. Furnivall found a cæcal fistula and inserted a tube. This tube he wore till the month of October, and through it the bowel was daily irrigated with nitrate of silver solution. As the motions by that time were practically normal, the tube was removed and treatment discontinued. The bowels at the present time are natural and regular, and he is in better health than he has enjoyed for years.

A word about the treatment of these cases. If the ulceration be of dysenteric origin, treatment with ipecacuanha in the usual way should be sufficient to effect a cure. This was not tried in the first case described, but there is no doubt that it should have been. In the non-dysenteric cases high irrigation of the colon with a solution of argyrol or protargol (1 per cent. of either) should be tried first. If this fails it is advisable to perform cæcostomy or appendicostomy, and wash out the bowel with the solution from above, as this is the only way by which one can be sure of reaching the whole of the mucous membrane. The second case narrated is a good example of the successful employment of this method.

CHRONIC CATARRHAL COLITIS.

Sometimes after an attack of acute colitis the diarrhoea does not disappear, but passes into a chronic form with the passage of mucus and sometimes of blood. Such cases are commonest in children in whom the acute disease is also most frequently seen. The following is a typical example:—

Ernest W., æt. 6, had an attack of acute diarrhoea and vomiting in the hot weather of the summer of 1904. The motions were very frequent, and attended by straining and the passage of mucus and blood. The vomiting subsided, but the diarrhoea became chronic and resisted treatment by drugs. The colon was irrigated with a solution of peroxide of hydrogen, but without success. A half per cent. solution of nitrate of silver was then employed instead, with the result that the diarrhoea immediately ceased, and a fortnight later he was discharged quite well.

Cases such as this are naturally more easily dealt with than those which have gone on to ulceration. Many of them will subside under treatment with bismuth and opium, but where the symptoms persist the use of astringent irrigations is strongly to be recommended. The above is a good example of their beneficial effect. Surgical interference should rarely, if ever, be called for.

CHRONIC ENTERITIS.

Passing from affections of the large bowel one may go on to speak of chronic diarrhoea which is

due to catarrh of the small intestine. Such cases are less easy to diagnose than those in which the diarrhoea is due to some affection of the colon, but a careful inspection of the stools should help to reveal the nature of the disease with which one has to deal. The dejecta in such cases show the presence of undigested fragments of food and of particles (often only to be seen under the microscope) of bile-stained mucus. Not infrequently too, the motions are pale and yeasty. It is difficult to be sure in such cases that one is not dealing with ulceration of the small intestine, but it is well to remember that ulceration alone apparently does not lead to diarrhoea, except when it coexists with some degree of catarrh. Hence it is that one may find extensive ulceration of the bowel in cases of tuberculous peritonitis, for instance, in which there has been no diarrhoea during life. The following case belongs to this group:—

Anne R., æt. 32, at the age of fifteen had an attack of "inflammation of the bowels," and has had chronic diarrhoea ever since. Her nutrition is wonderfully good considering the duration of her illness. There is no anæmia. The abdomen is distended and tympanitic, and coils of small intestine are sometimes visible. From four to six medium-sized motions are passed daily of a pale colour, frothy and very offensive, containing undigested food and small particles of mucus. Nothing can be felt by the rectum. A test-meal showed normal digestion. She was treated in bed on a diet of peptonised milk and farinaceous foods. Cyllin in 5 minimis doses every four hours removed the factor of the stools, and the administration of cuttle-fish bone and vegetable charcoal reduced them in number to one or two a day, and that of a solid consistence. They were still, however, very badly digested, a circumstance which pancreatine given in 5 gr. doses in keratin capsule every six hours failed to remedy. After the improvement in the consistence of the stools the abdominal distension became much less and the patient was discharged without, however, having materially gained in weight.

This case illustrates very well the long duration and the stubbornness to treatment which characterise chronic enteritis. It is easy enough to suppress the diarrhoea, which is the chief symptom of the intestinal catarrh, but it is much more difficult to restore the mucous membrane of the bowel to a normal condition. It is doubtful, indeed, if, when once its surface layer has been destroyed one can hope ever fully to restore the integrity of the intestinal epithelium. One is most likely to succeed by keeping the patient for a long time at rest in bed, on a bland diet, and by using bismuth in large doses, or better still, perhaps, salts of calcium, such as the phosphate or carbonate. I have had more success, as in the above case, with powdered cuttle-fish bone than with any other preparation. If there be much factor in the stools antiseptics are of help, cyllin being probably the most efficient, and if fermentation causes meteorism *fresh* vegetable charcoal is an aid. For colicky pains belladonna internally, and hot fomentations externally, are the best means at our command. When all is said and done, however, chronic catarrh of the small intestine is not a condition in which therapeutic triumphs are likely to be scored, and the patient is apt to suffer from it to a greater or lesser degree for years, though his sufferings may be much mitigated by minute attention to diet and by the avoidance of chill. Fortunately the condition, does not seriously impair health even when it counts its

duration by years, and nothing is more astonishing than to see how well nutrition is maintained in such cases in spite of a persistent and apparently severe diarrhoea.

GASTRIC DIARRHOEA.

I now pass on to speak of a form of chronic diarrhoea which is not so well recognised as it should be, and which, as it is primarily due to defective digestion in the stomach, may be appropriately termed "gastric" diarrhoea. A recital of two cases will make its nature clear:—

Constance R., *æt.* 20, had suffered from diarrhoea and occasional vomiting for two years. Her illness began with an acute attack of vomiting after eating some plums, and in spite of much treatment at various hospitals, she has suffered from more or less constant diarrhoea since. Any slight indiscretion in diet would also bring on vomiting. She was a fairly nourished girl in whom nothing abnormal could be made out by the ordinary methods of examination. The stools were at times pulsatous; at others liquid and bilious, containing undigested particles of milk curd and small portions of mucus tinged with bile or blood. A test-meal was badly digested and showed a low degree of acidity, with the presence of an excess of mucus but no free hydrochloric acid (chronic gastritis). She was kept in bed and put upon a milk and farinaceous diet. Bismuth, chalk, and calcium phosphate were all given in full doses, but without benefit. She was then put upon 20 minims doses of hydrochloric acid with 3 minims of tincture of opium, given half and again one hour after food thrice daily. On this great improvement resulted. The stools became solid and she gained in weight rapidly. One month after admission a test-meal showed that the gastric functions were normal. Six months later she came up to report herself in blooming health.

Abel K., *æt.* 56, a labourer, complained of diarrhoea and nocturnal incontinence of *fæces* of eight weeks duration. He was a man of excellent character and habits, a total abstainer, and had always enjoyed good health. *He made no complaint of any stomach symptoms.* The motions numbered six or more in the twenty-four hours, and were of a lightish yellow colour and their passage was often attended by scalding. He seemed to be a vigorous healthy man, and abdominal and rectal examinations were negative. He was treated as an out-patient with restricted diet and mixtures of chalk and opium, bismuth and opium, dilute sulphuric acid and lead and opium, but without any marked success. He was then admitted to hospital and the stomach functions tested on two occasions by a test-meal. Both examinations showed almost complete absence of gastric digestion, the total acidity of the contents being very low and [free hydrochloric acid entirely absent. He was then put upon full doses of hydrochloric acid after food, with the result that his diarrhoea ceased, and he was soon passing only one formed motion daily. Since that time—now two years ago—he has a few slight relapses which, however, have always yielded immediately to the same treatment.

We have here, then, two cases of chronic diarrhoea both of which resisted ordinary methods of treatment, until it was discovered that the gastric secretion was at fault. As soon as this was remedied the diarrhoea ceased.

How it is that a defective secretion of hydrochloric acid in the stomach results in diarrhoea in some cases it is not easy to say. It might be supposed that the badly-digested food, which enters the intestine excites a catarrh of which the diarrhoea is a symptom. This explanation, however, will hardly hold good, for in the first place the stools in such cases do not have the characters which are associated with enteritis, nor does catarrh of the small bowel yield so readily to treatment as is the case in gastric diarrhoea. It may be

that the absence of hydrochloric acid which is the normal antiseptic of the stomach, and to some extent of the intestine also, allows of an abnormal degree of intestinal fermentation and putrefaction which results in diarrhoea. It is probable, too, that direct stimulation of the small intestine by imperfectly digested food excites an exaggerated peristalsis. It is true that the pancreas should in ordinary circumstances be able to compensate for the action of the stomach and reduce any food which escapes digestion in the latter to a fluid form. It may well be, however, that in some individuals this compensatory action is not able to meet the demands upon it, and in such persons diarrhoea results. Be the explanation what it may, there can be no doubt that diarrhoea of gastric origin does occur, and that it can only be treated successfully when its source is recognised. One point about such cases must be emphasised—namely, that they do not always exhibit any symptoms which would lead one to suspect their gastric nature. In the second of the two cases mentioned the patient distinctly stated that he had never suffered from indigestion in any form, and yet examination showed that his secretion of gastric juice was greatly impaired. The moral is, that in every case of chronic diarrhoea one should investigate the functions of the stomach by a test-meal. In this way only can the nature of such cases be revealed and successful treatment instituted.

NERVOUS AND LIENTERIC DIARRHOEA.

You are aware that when no other plausible explanation of any morbid condition is forthcoming, there is a tendency to ascribe it to "nervous" influences. To this tendency chronic diarrhoea is no exception, and, consequently, one finds cases of so-called "nervous diarrhoea" described in the text-books. It is a wise rule, however, never to assume that a disease is due to purely "nervous" influences unless one can eliminate every other possible explanation of its occurrence. I do not wish to assert that "nervous" diarrhoea does not exist, but I am fairly sure that it is not a common complaint. It is customary to refer to this category cases of diarrhoea in which the increased frequency of the motions tends to be brought on by emotional excitement of any sort. It must be remembered, however, that any form of chronic diarrhoea is apt to be aggravated by such influences, and there can be little doubt that in many cases of supposed purely nervous diarrhoea there is an organic lesion at the root of the disturbance, usually, perhaps, a slight degree of chronic catarrh of the bowel. Notwithstanding this, it must be admitted that in a few cases no other explanation of a long-standing tendency to looseness of the bowels may be forthcoming other than that it is due to unusual nervous excitability. The following seemed to be a case of this sort:—

Alex. S., a schoolboy, *æt.* 14, had suffered from diarrhoea for about a year. The motions only occurred when he was up and about and amounted sometimes to as many as five daily. The evacuations were sometimes watery, sometimes formed, contained no blood nor mucus, nor was their passage attended by any pain or tenesmus. He seemed a perfectly healthy boy, and examination of the abdomen, stomach functions, and lower bowel was alike negative. Treatment outside had but little effect on the diarrhoea, although opium seemed to control it to some extent, but so soon as he was admitted to hospital the diarrhoea straightway ceased, even without any special treatment, and, indeed, gave

place to a condition of constipation. Inquiry some months later showed that he was remaining well.

The absence of any other apparent cause for the diarrhoea in this case and its immediate disappearance under the changed surroundings and "moral discipline" of hospital life strongly suggest its nervous origin.

The form of chronic diarrhoea to which the term "lienteric" is commonly applied may also be reasonably regarded as of nervous causation. In this variety, as you know, there is a tendency for the bowels to act immediately upon food entering the stomach. It is a condition most often met with in children and in the words of the mothers "The food seems to run through them!" We have here, I think, an exaggerated sensibility of the nervous mechanism of the alimentary tract, as a result of which the entry of food into one section of the canal leads, probably reflexly, to an immediate discharge of the contents of the section below. In favour of this view is the fact that the administration of small doses of opium before meals has an almost specific curative influence in them. Arsenic and nuxvomica are often recommended in such cases, but I have found them far inferior to opium in their power of controlling the diarrhoea.

THE HEREDITY OF OSTEITIS DEFORMANS.

By S. MAYNARD SMITH, M.B., B.S.LOND.,
F.R.C.S.,

Surgical Registrar to St. Mary's Hospital.

ALTHOUGH it is now some thirty years since Sir James Paget first described the disease we know as Osteitis deformans, we have in reality added no material facts to his observations—in fact, his original paper might well stand as a complete record of our present knowledge. In the series of articles published in the *MEDICAL PRESS AND CIRCULAR* of 1890, full and careful descriptions are given of a considerable number of cases, and since that time more and more instances of the disease have been published until now its recognition is frequent, and the cases met with receive little notice and but cursory investigation. There is, however, a point indicated by the title of this paper which has, I believe, never been insisted on, and indeed the fact involved, if it be a fact, has been explicitly denied. Sir James Paget (a) found no evidence of heredity in twenty-three cases. Joncheray (b) in an elaborate monograph says: "L'hérédité n'y est pour rien." What evidence is there then to justify a belief in the heredity of the disease? Amongst sixty-four cases collected from various sources I find the following records:—

(i.) Pickering Pick (1), in recording a case in a woman *æt.* 67, says that she remembered that her father's legs were very much bent and much in the same condition as her own for seven years prior to death.

(ii.) Stephen Mackenzie (2) describes a typical case and states that an elder brother had died with a crippling deformity of the lower limbs and was believed by the family to have had the same disease.

(iii.) Lunn (3) records the occurrence of the disease in two brothers.

(iv.) Kilner (4) describes with photographs a brother and sister suffering from the disease.

(v.) The writer of this paper showed a case of Osteitis deformans last year (5) in a man whose father was at the time in the Camberwell Infirmary, and an exceedingly good example of the same disease.

If the hearsay evidence in the above list be accepted, there was evidence of heredity in five pairs of cases out of a total of sixty-four cases. It is difficult to obtain any information as to relatives from the average hospital patient with this disease, coming under observation as he does at about the age of fifty. His parents are dead, his children are not old enough to show signs of the disease, his brothers have often been lost sight of. Again, since it is the bending of the legs which is the usual point to attract the attention of others, the demands of modern costume will cause the existence of the disease in a man's female relatives to pass unnoticed by him. Remembering these facts and recognising that in less than half of the recorded cases is there any definite statement of inquiry into family history, I think that the above figures give strong evidence of the existence of an hereditary factor in the causation of Osteitis deformans.

There is a condition found in the same disease which is unusual yet present in seven of the sixty-four cases. This is enlargement of the facial bones. The lower jaw and the alveolar margin of the upper jaw are the parts most involved. This is of particular interest, as the absence of affection of the facial bones is usually considered to constitute a striking feature of Osteitis deformans as distinguished from acromegaly.

CLINICAL RECORDS.

CASE OF

CHRONIC DIARRHŒA SIMULATING SPRUE.

*Under the care of P. T. O'SULLIVAN, M.D., B.Ch.,
Senior Physician to the South Charitable Infirmary, Cork; Physician
to St. Vincent's Hospital for Women and Children.*

Mrs. C., *æt.* 30, a 4-para., suffering from chronic diarrhoea for two years. She was thin, sallow, and worn, with very depressed expression. The diarrhoea was principally in the morning, no pain, but a good deal of discomfort. The motions were always large, and numbered four to eight in twenty-four hours.

Condition on Examination.—Teeth good, lips excoriated and pallid, tongue small, dry and glazed, split by fissures into small plaques. Anything acid or salt smarted considerably. Appetite fair, no thirst. She complained occasionally of distress after food, particularly vegetable food. The motions were large, white, and not very offensive, alkaline in reaction, exceedingly bulky and out of proportion to the food ingested. Under the microscope they showed no special features. Urine was normal, and although examined several times chemically and microscopically, nothing abnormal was detected, except that the excretion of urea was markedly reduced, the percentage being '47. Lungs normal, cardiac first sound feeble, accentuation of the second sound by contrast. Blood examination revealed marked diminution in hæmoglobin, but no other change in the cellular elements.

On examining the abdominal viscera, I could not

find the liver at first, but eventually a strip of dulness, two inches long, about the level of the nipple, was elicited, and palpation of the very flaccid abdomen revealed a hard band running up to the diaphragm. This condition gave the key to the disease. It was evident that the diarrhoea was due to the absence of (1) bile; (2) of the other functions of the liver. The patient was put on a rigid diet, getting her food practically dry, very little fluid, and that sterilised milk. Beta-naphthol in petroleum emulsion had no effect. Fat globules were subsequently detected in the fæces, and the patient was accordingly put entirely upon Benger's liq. pancreaticus, and in three or four days she had the first formed motion for two years. The size and number of the motions diminished, and after ten days bile appeared in the motions.

He considered that the case illustrated the interdependence of the functions of the liver and pancreas. His reasons for comparing it to sprue were:—(1) Morning diarrhoea; (2) its quantity; (3) condition of mouth and tongue, etc.; (4) the diminution of the liver. Sprue had never been known in this country, except in imported cases.

REPORTS OF TWO CASES OF COMPLICATIONS OF PURULENT EAR DISEASE.

By J. STODDART BARR, M.B., Ch.B.

Assistant Surgeon to the Glasgow Hospital for Diseases of the Ear, Nose, and Throat.

CASE 1.—A fatal case of septic thrombosis of the lateral sinus, secondary to chronic otitis media purulenta in left ear, and complicated with septic infarctions in the right lung.

The patient was a little girl, æt. 7 who had had a continuous discharge from the left ear for a year. During the eleven days before admission she had a dozen severe rigors, with violent oscillations of temperature from normal to 104° F. There was also frontal headache and pain in the left side of the neck. She vomited once or twice at the beginning of the illness. The discharge from the ear was profuse and fetid. There was evidence of the early stage of optic neuritis in both eyes. The breath was accelerated with frequent cough. A few moist rales were heard and also tubular breathing over a restricted area around the inferior angle of the right scapula. The radical mastoid operation was performed, clearing out pus and granulation tissue. The sigmoid sinus was exposed, and found converted into a yellowish sloughy-looking mass surrounded by, and partly filled with pus. The bulb of the internal jugular contained solid thrombus. The sinus was slit open backwards and cleared of septic disintegrated thrombi to within 1½ inches of the torcular when a gush of blood appeared. After the operation the pulmonary symptoms continued to increase, and the patient died two and a half days after admission to the hospital. *Post-mortem* examination was conducted by Dr. James Walker, and showed well-marked septic infarctions of the right lung. Bacteriological examination showed the presence of pneumococci and streptococci and also a large bacillus, which did not grow on the culture media, and did not give the staining reactions of the acid fast group of organisms.

In this case it is highly probable that had operative treatment been employed a few days earlier, before the pulmonary infection had supervened, a different result might reasonably have been expected. It should be emphasised that, when rigors with violent oscillations of temperature appear in connection with a purulent middle ear disease *operative treatment is urgently called for*. Judging from this case, and others of a similar kind, the grave significance of this symptom in these ear cases is not yet duly recognised by some practitioners. Operation carried out early is probably more successful than in any other form of intracranial complications due to ear disease; hence the vital importance of early recognition of the condition present.

CASE 2.—A case of Otitic Extra-Dural Abscess

associated with Paralysis of the Sixth Cranial Nerve, and Double Optic Neuritis. Operation and Recovery.

The patient was a lad, æt. 17, who suffered from purulent right middle ear disease for sixteen months before admission. He came to hospital owing to headache, diplopia, paralysis of external rectus (6th nerve) and double optic neuritis. The radical mastoid operation cleared out cholesteatomatous masses from the antrum, auditus and the attic of the tympanum. The opening of the sigmoid groove gave exit to a collection of pus between the sigmoid part of the lateral sinus and the bone. The sinus wall was involved and covered with granulation tissue, but there being no signs of general septic infection, it was not opened. There had been no pain over the mastoid area nor behind, and the temperature was normal from the time of admission. After operation the paralysis of the sixth nerve gradually but slowly passed off. The optic neuritis for a few weeks became more marked, with occurrence of hæmorrhagic spots and now, four months after the operation, the discs are undefined, with white spots and a tendency to atrophy, but the vision is so far unimpaired.

Remarks.—The pathological connection between the septic pachy-meningitis at the sinus and the lesions causing the ocular phenomena is not very clear. The most ready explanation is that a limited basal lepto-meningitis originated in the region of the sigmoid groove and extended and involved the sheath of the sixth nerve, or the more distant optic commissure, either by pressure or by producing an infective neuritis. There is also the possibility of the formation of a thrombus in the cavernous sinus, originating in the sigmoid and, by pressure involving the sixth nerve as it lies in the cavernous sinus, or by producing stasis of the blood from the eye, causing optic neuritis. It is also to be remembered that optic neuritis seems to occasionally occur in connection with simple purulent middle ear disease presenting no intracranial symptoms.

THE OUT-PATIENTS' ROOM.

WEST-END HOSPITAL FOR DISEASES OF THE
NERVOUS SYSTEM.

Cerebral Diplegia.

By FREDERICK S. PALMER, M.D., M.R.C.P.

THE three cases briefly described below have been recently brought to the out-patients' department of the Hospital with cerebral palsies of bilateral distribution.

CASE 1.—D. W., female, æt. 7, the second of nine children, of whom five were stillborn. Both parents are living and apparently healthy. The mother states that during the whole of her second pregnancy, which terminated at the eighth month, she never felt well. She suffered from intermittent abdominal pain, and had a succession of family troubles and worries. Four days before her confinement she fell downstairs and cut her left foot so severely that six sutures were inserted to bring the edges of the wound together. The labour was quick, and not attended with any difficulty or complication. The child was, however, more or less asphyxiated at birth, and had convulsions shortly afterwards, followed by snuffles; but she never observed any rash. The fits continued at irregular intervals until the seventh month, but have not recurred since then. She began to talk at fifteen months, but she has never been able to walk or to stand alone. The cranial circumference is 18 inches. Her intelligence is good, she answers questions correctly at once, and has been able to learn a few easy lessons. Her disposition is said to be amiable and affectionate. She is able to feed herself, but has no control over the sphincters. She has well-marked spastic paraplegia, the knees are pressed firmly together by the adductor spasm, and the toes are over extended. In any attempt to flex the legs the so-called lead pipe resistance is encountered. The knee-jerks are much exaggerated, and the plantar response on each side is of the extensor type. The ankle jerks are obtained, but ankle clonus is absent. On

being supported by her mother, the child attempts to walk in the typical, spasmodic, cross-legged, digitigrade manner, with the heels raised, and the toes just touching the ground. The muscles of both legs are small, but there is no evidence of marked vaso-motor disturbance. She has also considerable weakness of the left upper extremity with hyperkinesis. The post-plegic athetoid movements are chiefly tentacle-like in character, the digits being widely separated, and over-extended, but the excursions are of short range and cease during sleep. There is no involvement of the facial muscles, nor any affection of the cranial nerves.

CASE 2.—F. F., æt. 6 (the youngest of six children), was born prematurely between the seventh and eighth month. His mother died eight months ago from carcinoma of the breast. According to the statements of the father, the other children were all born at term, and are healthy and well. A few days before the birth of this child, his mother had a severe fright from the children setting fire to some shavings in the room, which she had difficulty in extinguishing. The labour was precipitate, and the child was born before either a doctor or a nurse could be summoned. He has never had any convulsions. The cranial circumference is 18½ inches. His mental condition is slightly below the normal, but he has full control over the sphincters. He did not begin to talk till three years ago, but since then his intelligence has improved. He has never been able to stand or walk alone, and he has difficulty in raising himself into an upright position without assistance. On examination, he presents the same physical disabilities as the last child, spastic paraplegia, adductor spasm, exaggerated knee-jerks, extensor type of plantar response, scissor-like digitigrade progression, lead-pipe resistance to passive movements, with some slight rigidity of both upper extremities. The cranial nerves are normal. There are no athetoid movement and ankle clonus is not obtainable.

CASE 3.—L. M., female, æt. 4½, the second of three children, born at time. The mother admits she was in bad health during her pregnancy, suffering from what she described as a "nervous breakdown," and that her confinement was rapid. Her first child was still-born at the seventh month, and she miscarried with the last between the fourth and fifth month. No history of convulsions can be elicited. The patient is very backward, and it is not long since she commenced to talk. Her cranial circumference is 18½ inches. She is unable to stand alone. Her intelligence may be described as distinctly inferior to the previous two diplegics, although she quite understands what is said to her. She repeats her name and address quite correctly, but evidently does not appreciate the attention of strangers. The organic reflexes are perfectly normal. Her knee-jerks are only slightly exaggerated, there is no ankle clonus, but the extensor type of plantar response is at once provoked by the least stimulation of the soles. When made to stand and to attempt to walk she advances very slowly in the usual cross-legged fashion, in the position of talipes equino-varus. The adductor spasm in this case is very marked, holding the knees tightly together. On careful examination a tendency to post-plegia movements is observable in both upper extremities, but there is no definite evidence of motor weakness in the arms, nor any defects to be noticed in the cranial nerves.

Remarks.—The three cases just described may be regarded as good examples of cerebral diplegia, varying slightly in degree, of the type designated by Freud "paraplegic rigidity." They follow the rule that in the majority of these unfortunate children some grade of mental enfeeblement is usually present, in association with the physical disability. Two were born prematurely, and one at term. In all, the labour was precipitate. There is the history of previous ill-health during the pregnancy of two of the mothers, and also of shock and fright, a few days before delivery—not uncommon factors in the etiology. In one, if not in two, the suspicion of specific disease in the

parents, which is known to play an important part in these affections, is suggested as a possible explanation of the previous ill-health.

The diagnosis of these cases, as a rule, is not difficult, but in those that are not well marked, they may have to be distinguished from anterior polio-myelitis, spinal caries with compression paraplegia, Friedreich's ataxia, insular sclerosis (rarely seen in children) pseudo-hypertrophic paralysis, Thomsen's disease, intracranial neoplasms, and the rigidity sometimes seen in rachitic children. The points which distinguish the infantile cerebral palsies are the history, mode of onset, distribution of the paralysis, spasticity of the affected limbs, behaviour of the reflexes, the presence of mental impairment, or post-plegic automatic movements, and the absence of marked amyotrophy, or change in the electrical reactions. The pathology of these cases is at present more or less obscure—opportunities of investigating the morbid processes in their earlier stages is seldom afforded. Those revealed on necropsy relate chiefly to secondary or terminal conditions. Briefly, they may be summed up as follows:—Developmental anomalies, vascular lesions, meningeal, and intra-cerebral, or inflammatory changes, leading to atrophy, and sclerosis of the convolutions, areas of softening, and cavity formation (porencephaly). The view most commonly accepted is that of primary progressive degeneration of the neurons of the cerebral cortex from toxic causes. The disability is not in any way dangerous to life, the anxiety chiefly concerns the growth and mental condition of the child, or the onset of epilepsy. Attention to the general health, passive movements of the affected limbs, regular and systematic gymnastics, and the individual training, and educational methods practised in the institutions for the feeble-minded, together with appropriate surgical measures for the prevention, or restoration of deformities arising from contractures are the principal indications in the treatment.

OPERATING THEATRES.

GUY'S HOSPITAL.

TWO AMPUTATIONS OF BREAST.—MR. CLEMENT LUCAS operated on a woman, æt. 60, who was suffering from an extremely retracted and adherent nipple of the left breast. She was a married woman who had borne several children, now grown up, but she had never suckled them with either breast owing to the inversion of both nipples. She had after some of her labours had the milk drawn off by artificial nipples; she was in other respects a healthy woman, with a good family history. She had had an attack of influenza about Christmas time, and it was about this period that she noticed some alteration in the left breast. She said nothing about it, however, till March, when she was persuaded to tell her doctor of it, who referred the case to Mr. Lucas. The breasts were both small, and the left one different from the right only in the fact that the inverted nipple was adherent to the parts beneath and had a firm marginal areola, the breast being thus pinned down in the middle; the rest of it felt soft and free of all tumour growth, but when an attempt was made to move it over the pectoralis major muscle it was clearly adherent to the parts beneath. No enlarged glands could be felt in the axilla. M. Lucas stated that retracted nipples bore a double relation to carcinoma. They might be either a cause or a consequence of the disease; he always regarded retracted nipples as a serious defect, more especially in married women as greatly increasing the tendency to carcinoma as age progressed. This defect he considered acted in two ways; in the first place the fossa always present secreting an unctuous substance, in which minute organisms would tend to collect and

procreate in association with dust and dirt, afforded a direct means of entry to the substance of the breast; in the second place, lactating women failed to empty their breast at the call of the infant, and thus in the breast substance undischarged secretion often collected and was imperfectly absorbed. The natural physiological action of the breast was therefore never properly carried out during the lactating periods. The diagnosis of carcinoma, he pointed out, in this case rested on three facts; (a) the hard margin of the fossa caused by the inverted nipple; (b) the adhesion to the deeper parts; and (c) the age of the patient. The retraction of the nipple, he said, had preceded any growth, and was present also in the other breast. There were no enlarged glands to be felt in the axilla to aid in the diagnosis. The age of the patient suggested carcinomatous rather than inflammatory adhesion. Mr. Lucas, therefore recommended removal of the whole breast and clearing out of the axilla. In doing this it was found necessary to remove the fascia and some of the muscular substance of the pectoralis major muscle. In clearing out the fat of the axilla a few small glands were found apparently not enlarged or infiltrated. On cutting a section of the nipple a narrow white margin corresponding to the areola was shown, and on microscopical examination this proved to be carcinoma; the pathologist subsequently reported that the glands in the axilla showed no indication of growth. This was, Mr. Lucas remarked, a so-called atrophic cancer of the older writers, in which the growth proceeded slowly in an aged person without any great tendency to spread by the lymphatic channels.

The second case was that of a married woman, *æt.* 43, who also had borne children many years previously. She had a very prominent left breast in which she had discovered enlargement some months before, but within the last month the swelling had rapidly increased in size. When examined a fluctuating swelling was found at the upper and inner part of the breast just external to the areola; the nipple in this case was well developed. Irregular masses were to be felt in the breast on the axillary side of the organ; these swellings were firm, but not hard, and the organ itself moved freely upon the muscle beneath. There were no glands to be discovered in the axilla. Mr. Lucas regarded this as a degenerate breast undergoing involution with cystic formation, and possibly sarcomatous growth. The fluctuating spot was tapped, the fluid drained off, and examined microscopically. It was a grumous turbid fluid, not like true pus, and under the microscope showed for the most part broken down granular material and also some blood and pus corpuscles. Mr. Lucas advised the removal of the whole breast as the proper course to be adopted in all cases of tumour of the organ in women over forty years of age. This was accordingly done. After removal the breast was cut in sections to determine whether it would be necessary to explore the axilla; it was found that there was a large cavity above the nipple containing degenerate material; growths were discovered in other parts of the breast, which showed no glistening surface, but which might have resulted from mastitis or adeno-cystic formation. The axilla was therefore left unexplored. The microscopic examination of the growth showed it to be a myxo-adenoma in which inflammatory or degenerate changes were taking place. Mr. Lucas said it was obvious that any other course than the complete removal of the breast would in this case have led to no satisfactory result. Supposing the degenerate part had been incised and drained, a similar condition would have continued in the tumour growth in other parts;

fresh incisions would have been required there and after suffering months from open wounds the patient's condition would have remained unsatisfactory, and even if the wound had afterwards healed, the degenerate breast with its cicatricial tissue would have been a source of danger in later years from carcinoma.

As the result of complete removal primary union took place, and the patient was able to resume her ordinary occupation in the course of a fortnight.

ST. THOMAS'S HOSPITAL.

OPERATION FOR DEFLECTED NASAL SEPTUM.—Mr. H. BETHAM ROBINSON operated on a man, *æt.* 30, who had been admitted with nasal obstruction of some years' duration, especially affecting the right nasal cavity. On examination it was found that externally the nose was deformed with a distinct bend in the bridge to the right side; internal examination showed on the right side that the septum was bent so much as to completely touch the external wall. On the left side the upper part of the septum was deeply concave, corresponding to the convexity on the other side; this concavity ended below in a very sharp angled spur which practically filled up the whole of the inferior meatus. The spur or ridge traced backwards joined behind another sharply marked vertical angle which was just in front of the anterior end of the middle turbinate. Behind this the left middle turbinate was slightly enlarged. On operating on this case a submucous resection of the septum was done. Owing to the very limited room on the right side, contrary to the ordinary practice, it was decided to resect from the concave side. An incision was made down the vertical angle and then forwards along the spur; a triangular flap of muco-periosteum was raised from behind forwards with a raspatory exposing the bare white cartilage; a small incision in the front of this cartilage was made, an elevator passed through the hole in the cartilage and the muco-periosteum of the right side carefully separated. A large piece of the cartilage was then removed with a Kilian's knife. As in many of these cases, some difficulty was experienced in removing the thickened bent vomer, especially at the junction behind of the two angles; the bone, after separation of the soft parts with an elevator, was removed with a gauge; it was then found that good patency of the right nostril was obtained. The flap of muco-periosteum was then placed back in its proper position, and no stitches were put in. A rubber nasal splint was introduced into the right nostril to push the septum into a median position, and on the left side against the wound a couple of strips of cyanide gauze powdered over with aristol were placed. Mr. Robinson commented on the satisfactory nature of this form of operation for deflected septum; he had adopted in all similar recent cases the method of raising the flap of muco-periosteum from behind forwards as suggested by Freer of Chicago. The most difficult part of the operation he considered was the removal of the septum at the junction of two angles, it usually being bony, and then composed of the lower part of the perpendicular plate of the ethmoid, and the adjacent thickened upper part of the vomer. With the reflection of the flap from behind forwards and the incision into the cartilage as far forwards as possible, if a perforation should be here made through the muco-periosteum of the opposite side, the hole would be covered over when the reflected flap was replaced. Mr. Robinson said he preferred to do this operation under a general anæsthetic. He pointed out also that he used support to the septum for a very short period; the patients generally leave the hospital at the end of a week. He said that the septum formed by the approximated two layers of muco-periosteum—which, of course, is at first quite flabby—gradually becomes more rigid from the formation of fibrous tissue, so firm in some cases does it seem that it has been a point of discussion whether true cartilage is not reproduced.

The splint and the gauze were removed on third day, and no further treatment was required: the patient left the hospital at the end of a week.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD MARCH 30TH, 1906.

President, MR. CLUTTON, in the Chair.

MR. A. E. J. BARKER narrated a case of Treitz's Hernia complicating gastro-enterostomy. On opening the abdomen with a view to doing [gastro-enterostomy for carcinoma of the stomach, no small intestine was found within the peritoneal cavity. At first this was difficult to explain, but when it was seen that the colon was higher up than usual and that the anterior layer of its mesentery was bulged forward the position of all the small intestine behind the latter and a Treitz's hernia were recognised. The relation of parts rendered it necessary to open the sac of the retro-peritoneal hernia in order to examine the posterior aspect of the stomach with a view to the retrocolic gastro-enterostomy. In the sac was all the small intestine. The stomach was too extensively infiltrated with cancer for the anastomosis. Mr. Barker commented on the difficulties which would be met with in such a case in completing a gastro-enterostomy. Fortunately these cases were comparatively rare.

MR. E. PERCY PATON narrated a case of Right Duodenal Hernia, in which the hernia was reduced but death followed in seven days, due apparently to gut re-entering the sac. The patient was an infant, æt. three months. The illness started suddenly with symptoms similar to those of intussusception. A swelling could be felt in the abdomen. Laparotomy revealed considerable length of small intestine which appeared to be engaged under a peritoneal band. This gut was drawn out. No further investigation was possible owing to the general condition of the child. The patient was at once relieved by the operation, but was taken suddenly worse on the seventh day and died. At the *post-mortem* a right duodenal hernia was found into which a considerable quantity of gut had returned, which, however did not seem to be strangulated. There was no peritonitis. The paper was illustrated by photographs and also by the specimen which is now preserved in the College of Surgeons' Museum.

MR. F. EVE related the case of a woman, æt. 64, in which he had met with a duodenal hernia during the performance of a colotomy for chronic obstruction.

MR. FREDERICK EVE read a paper on Large Cysts of the Common Bile Duct.—A woman, æt. 46, was admitted in November, 1902, with an abdominal tumour and jaundice, which had existed for three years. The tumour extended from the right costal margin to the iliac crest and across the abdomen to the left of and below the umbilicus; it was evidently elastic. It was thought to be a cyst of the pancreas. At operation the cyst was opened, and it was attached to the parietis. It contained 7½ pints of clear fluid, pieces of grit, and clinical examination showed bile pigment. The fistula remained open and seven months later a communication was made between the cyst and the hepatic flexure of the colon (choleoducto-enterostomy). She recovered from the operation, but died two weeks later of progressive emaciation and exhaustion.

Autopsy.—The abdomen was normal, with the exception of the large cyst of the common bile duct, 4½ inches in diameter. The junction with the colon was firm. Within the cyst and just above the papilla biliaris was a papilloma which had acted as a ball-valve. Commenting on recorded cases, Mr. Eve did not think that the condition was extremely rare, for in only a cursory examination of records he had found 24 cases. As regards causation the cases fell into three groups:—

(1) Those in which the obstruction was due to a vascular formation, to stenosis, or to obliteration; (2) obstruction due to calculus; (3) obstruction by a growth. Only one case besides that recorded had been

found. *Treatment:* In the great majority of cases the cyst had been opened and drained, with the exception of those, including the writer's, with a fatal result, which was mainly due to progressive emaciation and weakness from persistent jaundice. Some cases had been treated by uniting the cyst with the duodenum, jejunum, and in the cases recorded, the colon. The writer thought that this was a matter of choice; and in the majority of cases the colon was indicated on account of the extensive adhesions and the alteration of relationship of parts.

MR. F. C. WALLIS read notes of Three Cases of Gastro-jejunosotomy. The first case was that of a female patient, æt. 91, who made an excellent recovery, losing all the symptoms for which the operation was done. The patient died twelve months later from cerebral thrombosis. The other two cases were both instances in which chronic inflammatory thickening around an ulcer simulated a new growth both in appearance and to the touch. In both cases a posterior gastro-jejunosotomy was done. In the one case when the abdomen was re-opened a month later to do a partial gastrectomy the "growth" had almost entirely disappeared, and an ulcer on the posterior wall could be felt through the anterior. The patient has quite recovered and gained weight. In the other case the supposed growth occupied the cardiac half of the stomach. The operation relieved the pain which was the main symptom complained of, but the patient died on the fourth day from hæmorrhage. A *post-mortem* showed a large ulcer situated on the posterior wall, a large vessel ran along the floor of the ulcer, and in the middle of the vessel was an oval opening. Mr. Wallis remarked that the first case illustrated the fact that even very old people stand operations well, when their tissues are young. The lessons he learnt from the other two cases were (1) that in the majority of cases when partial gastrectomy is under consideration a posterior gastro-jejunosotomy should be first performed. (2) That delays are dangerous in cases of gastric pain which do not readily yield to medical treatment. Under such circumstances the abdomen should be opened and the stomach examined. A gastro-jejunosotomy can be done, and if there has been hæmatemesis to any marked degree, the stomach should be opened through healthy tissue in the neighbourhood of the ulcer, and the ulcer either cut out, cauterised or ligatured to prevent further hæmorrhage.

MR. HALE WHITE emphasised the fact that old age should not in itself be a bar to even serious operations. He had seen Mr. Wallis's first patient, and was much impressed by the relief she had experienced. The second group of cases was extremely important, and he wished to refer in this connection to masses of inflammatory material arising from the gall passages and simulating new growth, by causing pressure on the pylorus. He had seen such a case recently, and was convinced of the presence of pus owing to the high leucocytosis present; he had great difficulty in inducing the surgeon to incise the mass, which closely resembled cancer, but after evacuation of the pus the patient made a complete recovery.

DR. DE HAVILLAND HALL related a case recently under his care in which great benefit was obtained by simple laparotomy alone.

MR. W. G. SPENCER referred to the anomalous course often pursued by gastric cancer, and warned against too soon assuming that the diagnosis of cancer was incorrect, merely because great improvement followed operation.

THE authorities of the War Office have appointed Mr. W. J. F. Middlemiss, L.D.S.Ed., as Dental Surgeon to the Troops in Ireland, and Mr. E. H. Wyand, L.D.S.Eng., in a like capacity to the troops at Aldershot.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD MARCH 16TH, 1906.

DR. G. A. SUTHERLAND in the Chair.

DR. ERIC PRITCHARD exhibited a case of Symmetrical Dimpling of the Skin on the dorsal aspect of the extremities of both acromial processes in a girl *æt.* 8, the condition being noticed at birth.

DR. KENNETH R. HAY exhibited a case of Achondroplasia. J.K., *æt.* 2, may be considered to be a typical example of the condition called achondroplasia. He is the elder of two children. The younger is *æt.* four months, and is to all appearances normally shaped. The father suffers from phthisis and has been subject to fits, probably epileptic in nature. The mother is not a robust woman but says she has always enjoyed good health. There is no history of syphilis. His intelligence is perhaps rather below the normal for a child of his age. He can pronounce the words "daddy" and "mummy" but otherwise does not talk. He is inclined to be irritable and to resent any interference. He can stand, and also walk a little with aid but is very unsteady. In the standing position the typical lumbar curve is well seen. The head is decidedly large, and the frontal bones prominent. The root of the nose is depressed. The anterior frontanelle is open. The circumference measures 20½ inches. The body is long relatively to the limbs, and the chest rather narrowed. There is slight beading of the costochondral joints of the ribs. The heart and lungs are normal, and the sexual organs well developed. The limbs are shortened in a characteristic manner. The hands and fingers are dumpy. The humerus and ulna each measure 3¾ inches. The femur measure 4½ inches, and the tibia 5 inches. The bones feel thick and hard and are not apparently curved.

MR. HUGH LETT exhibited (1) a case of Erb's Paralysis in a child, *æt.* 4½ months, involving the fifth, sixth, and seventh cervical nerves; and (2) a case of precocious development in a boy, *æt.* 4. He had been rather backward until he was two years old, the pubic hair then appeared, and development took place with extreme rapidity. There was a remarkable growth of hair all over the body, especially over the pubes and in the lumbar region. The penis and testicles were large and resembled those of a young adult. His voice was deep and like a base voice, not yet under full control. His muscular development was remarkable, especially in the thighs, and he was possessed of proportionately great physical strength. A skiagram of the wrist showed ossification taking place in all the bones of the corpus, and one of the knee presented the appearance of the joint in a boy 17 or 16 years old. No enlargement of the thyroid or suprarenal bodies could be made out. His appetite was voracious. Intellectually he was bright, but had a terrible temper. He had nocturnal enuresis. He had had no fits, and was not subject to headaches.

DR. POYNTON exhibited a case of Acne-Scrophulorum. D.W., *æt.* 5½ a delicate child with somewhat large cervical glands, and a history of tuberculosis on the mother's side. The rash commenced upon the arms and legs, in the form of discrete papules, which at first itched very slightly. Since that time these papules have been coming out in crops, some of them appearing on the trunk, and an occasional one upon the face.

MR. SIDNEY STEPHENSON showed a case of Congenital Coloboma of the Eyelid in a boy, *æt.* 3 months, who was brought to the Evelina Hospital on account of a deformity of the right upper lid, present since birth. Upon examination a quadrangular gap was seen in the right upper eye-lid. It involved the inner half of the lid with the exception of a small nodule at the inner end, and extended about half way from the orbital to the palpebral margin. The puncta lacrymalia were present, the upper one being situated on the nodule mentioned above. When the baby shuts his eyes, the right cornea and pupil can be seen through

the gap in the eyelid, thus producing a somewhat weird effect. There is no particular thickening of the palpebral conjunctiva, no lipo-dermoid of the conjunctiva, no dermoid of the cornea, and no coloboma of the iris.

MR. H. S. CLOGG exhibited a case of Congenital Deformity of the Hands. Baby, *æt.* 4 months at present time. The infant is one of twins, the other child being perfectly well formed. There is nothing in the family history of any importance. The *right hand* is shortened and comparatively broadened. Some power of flexion appears present in the terminal stump. The fingers of the *left hand* are curiously bound together at their distal extremities. The proximal portions of these are free from one another, and the webs are not unduly prolonged down upon the interdigital clefts. The distal halves of the digits are fused together, apparently by soft tissues only, and overlapped in a curious way.

MR. DOUGLAS DREW exhibited a case of a Congenital Unilocular Cyst of the Neck.

DR. W. EWART exhibited drawings of a child recovering from "Chorea" and read a short paper on the treatment of chorea by strychnine. He said that strychnine is to be prescribed as a nervine and general tonic, and though it has to be pushed, any approach to toxic symptoms is carefully avoided, this is best secured by the combined influence of ammonium bromide. Obvious benefit has been obtained in children of 6 to 12 years of age from doses of the liquor from mm. x to m. x. administered three times daily and guarded by bromide.

DR. EDMUND CAUTLEY showed a specimen of Congenital Hypertrophic Stenosis of the Pylorus removed from a child, *æt.* 9 weeks, one of twins born somewhat prematurely. Symptoms began at three weeks of age. The child came under treatment a week before death, weighing 3 lbs. 7 ozs. The vomiting was by no means marked. A normal stool was passed a few days before death. The case illustrated moderate pyloric hypertrophy which had not produced complete obstruction, nothing in the history suggestive of spasm.

DR. C. O. HAWTHORNE read notes on a tumour of the Pons Varolii in a boy, *æt.* 8.

DR. C. O. HAWTHORNE read notes on specimens from a case of small white kidney from a girl of 12. The microscopic changes are those of chronic interstitial nephritis.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD WEDNESDAY, MARCH 28, 1906.

The President, DR. KELLY, in the Chair.

DR. WILSON, of Calderbank, read notes of an interesting case of

PURPERAL ECLAMPSIA

in a young woman, *æt.* 22. She was six months pregnant, when convulsions set in, with involuntary passage of urine. Some urine was procured by means of a catheter, but there was no albumen present. There was no oedema discernible. She vomited dark-coloured material. She was treated with chloral, which relieved the fits for a time. Pilocarpine and saline transfusion were also tried. But the coma deepened, and on the third day of the illness she died.

In the discussion that followed no definite or general finding of the members was arrived at as to the cause of the eclampsia in this young woman, who was supposed to be healthy in every respect. But there was no information as to the state of the pulse tension, and whether the specific gravity of the urine was low, which would have pointed to renal insufficiency. In not a few cases, an early history of scarlet fever with renal dropsy can be made out on close investigation of the history of the case.

DR. WILSON showed two small masses of a bifurcated tumour which he had removed from the roof of an infant's mouth. The tumour had grown from the base of the skull, penetrating a cleft palate, and pre-

venting the baby from sucking the breast. It proved to be a dermoid tumour, on microscopical examination.

Dr. FREW read a paper on the

RESUSCITATION OF STILL-BORN BABIES.

criticising the various well-known methods practised, and laying particular stress on hot-water douches over the region of the heart.

Dr. MACLACHLEN related his experience in dealing with profound cases of alcoholic poisoning, where the pupils were dilated, and insensitive to light, the pulse not perceptible to the touch, and no appearance of respiratory movement. In such cases he contended that the first thing to do was to start oxidation by stimulating the respiration, by flagellation of the chest, with a wet towel. This flagellation may have to be kept going off and on for ten to thirty minutes. The first effect noticeable is that deep inspirations are taken, and the strong odour of alcohol, being exhaled becomes pronounced. Patients brought into the Northern Police Office stony-cold from alcoholic poisoning, are generally "brought round" at the outside in half an hour.

Several specimens were shown. The PRESIDENT exhibited a large sarcoma of the uterus, with a portion of a fish-bone lying on the ovary.

Dr. LINDSAY showed an amorphous foetus of a cow, which was not unlike a hedgehog.

Dr. JARDINE produced the uterus of a woman who had had Cæsarian section performed twice.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL AND OTOLOGICAL ASSOCIATION.

MEETING HELD FRIDAY, MARCH 9TH, 1906. (Rooms of the Medical Society of London.)

The President, Dr. WOODS, in the Chair.

Mr. STUART-LOW showed a case with greatly enlarged Eustachian tubes, the remarkable feature of the case being the absence of symptoms of nasal or of pharyngeal obstruction.

Mr. STUART-LOW also showed a case of

ULCERATION OF THE AURICULAR LOBULE of fifteen years standing. The patient said that fifteen years ago the lobule of the ear had been pierced with a stocking needle by a friend for the purpose of wearing an earring. Ever since there had been trouble with it, as it never healed and had gradually a red scaly patch over the posterior surface of the lobule. A small piece was removed for microscopical examination, when it was pronounced to be lupus vulgaris. But under treatment with the ointment of nitrate of mercury it had nearly disappeared in two weeks.

Mr. DENNIS VINRACE favoured the diagnosis of lupus, and laid stress on the absence of local glandular enlargement and the chronicity in support of his conclusion.

Dr. NELSON thought it was a patch of chronic eczema, on the following grounds. (a) There was hardly any scarring after fourteen years. (b) There had been very marked improvement under dilute nitrate of mercury ointment. (c) Although the patch had never healed it had very nearly done so, and then relapsed.

The PRESIDENT, while recognising the difficulty of the case, was inclined to regard it as one of lupus.

Mr. MAYO COLLIER showed a case of

SYPHILITIC DISEASE OF THE LARYNX,

the object being to accentuate the fact that under ordinary syphilitic treatment the larynx did not heal. When this case came under Mr. Collier's care, after some months of general treatment, he ordered calomel fumigations or inhalation every second day, stopping the internal administration of medicine. The larynx healed well in three weeks.

Mr. HAROLD BARWELL thought the larynx was now healed, though some inter-arytenoid out-growth was present. He considered that the patient appeared to be more ill than would be expected from the laryngeal condition alone.

Mr. HAROLD BARWELL showed a case of

LUPUS OF LARYNX, PALATE AND PHARYNX.

Mr. LACK said this was a most interesting case, it resembled the condition of a patient who had been under his treatment for about three or four years, and who did exceedingly well after removal of the affected epiglottis, &c., by punch, forceps, and the after application of lactic acid. The patient was a girl now about fourteen years of age, and differed from Mr. Barwell's case in having lupus also of the vestibule of the nose.

Mr. DRINKWATER remarked that in Mr. Barwell's patient, on the border of the left inferior turbinal at the junction of the middle and posterior third, there is a nodule, and the mucous membrane of the inferior meatus below this point looks very suspicious.

Mr. CHICHELE NOURSE exhibited two cases showing the result of the "Radical mastoid operation."

CORK MEDICAL AND SURGICAL SOCIETY:

MEETING HELD MARCH 14TH, 1906.

DR. P. G. LEE in the Chair.

TWO CASES OF MYOMECTOMY.

PROFESSOR PEARSON showed fibroid tumours, removed from two unmarried women, æt. about 30. In the first case he diagnosed either ovarian tumour or a sub-peritoneal fibroid. The uterus was of normal size. On opening the abdomen he found a large fibroid attached to the uterus by a short pedicle two inches wide. The great size of the vessels in it, and their thin walls, negated the use of the ligature, so he made two peritoneal flaps, and used a continuous suture. This failing to make the stump staunch, he put on a Braithwaite's clamp, and stitched the stump to the parietal peritoneum, in order to prevent dangerous adhesions. He left the clamp on for six hours. Recovery was uneventful. The tumour was of the kind described by the late Lawson Tait as "œdematous." In the second case there were three tumours. The largest, about the size of an orange, lay over Poupart's ligament, and simulated a hernia. It was attached to the right cornu of the uterus, and was easily removed. The second, on the anterior wall behind the bladder, had to be enucleated, whilst the third, on the posterior wall, had a very short sessile pedicle. Recovery uneventful. As a rule he was averse from the operation of myomectomy, preferring hysterectomy in such cases, but he was reluctant to deprive these women of their uteri so early in their sexual life.

Professor CORBY agreed that the major operation was the more satisfactory as a rule, but thought it only fair to choose the minor in these particular cases.

CHRONIC DIARRHŒA SIMULATING SPRUE.

Dr. O'SULLIVAN read notes of a case, which will be found in another column under the heading of "Clinical Records."

LARYNGOLOGICAL SOCIETY OF LONDON.

MEETING HELD MARCH 2ND, 1906.

DR. WATSON WILLIAMS, one of the Vice-Presidents, in the absence of the President, occupied the Chair.

Mr. H. BARWELL showed two cases of Tuberculous Laryngitis, which had benefited by local active measures and sanatorium treatment.

Dr. H. J. DAVIS exhibited a case of Atrophic Rhinitis.

Dr. WALKER DOWNIE showed recent photographs of some cases of paraffin injection for nasal deformity, as well as others taken immediately after treatment, four years ago. In the discussion which followed, there was a consensus of opinion that with such good results from the use of paraffin for overcoming definite nasal deformity, the theoretical objections put recently forward by a German doctor, and quoted by Sir Felix Semon at the previous meeting, need not be taken too seriously. Dr. BROWN KELLY exhibited a sketch of a

larynx and the microscopic section of the uvula from a case of hyperplastic congenital syphilis.

Mr. BETHAM ROBINSON showed a case of Fibro-Angioma of the Nasal Septum, and Mr. H. SMURTHWAIT exhibited again for further diagnosis a patient previously shown to the Society in June, 1905. Several opinions were expressed at that time in favour of malignant disease of the larynx. The improvement which had taken place in the interval, without operative measures; had negated the opinions previously expressed.

Cases were also shown by Dr. H. Pegler, Mr. E. G. Waggett, Dr. Furness Potter and Mr. de Santi.

THERAPEUTICAL SOCIETY.

MEETING HELD (in the Apothecaries Hall, Blackfriars) TUESDAY, MARCH 27TH.

SIR LAUDER BRUNTON, President, in the Chair.

DR. GORDON SHARP, of Leeds, read a paper on NATIVE AND OTHER PLANTS HAVING SOME RELATIONSHIP TO CURARE,

including (1) *Anchusa officinalis*, Alkanet, an imported plant containing an alkaloid; (2) *Echium vulgare*, Viper's Bugloss, an indigenous plant, containing an alkaloid; (3) *Cynoglossum officinale*, Houndstongue, a common plant, containing two alkaloids. All belong to the Boraginaceae. *Anchusa* renders a frog's skin moist and hyperæsthetic at first, but afterwards insusceptible to stimulation, while the stimulus to the sciatic nerves or the muscles themselves causes contraction. The heart stops in diastole, and atropine only produces a few contractions of the left auricle. *Echium* causes the same symptoms with more hyperæsthesia, and greater weakness of the muscles. After a large dose no stimulation of the sciatic nerve causes any contraction, though the muscles react to direct stimulation. The heart stops in diastole. *Cynoglossum* renders the skin moist and very hyperæsthetic, but stimulation to either the sciatic nerves, or the muscles directly, only affects the unpoisoned side. It often acts somewhat like curare, but frequently death occurs suddenly with the heart in diastole. Among foreign plants the *Delphinium bicolor* and *occidentale* from North America, and the *Delphinium scopulorum* from Mexico, resemble somewhat curare. Their extracts are bitter, with a slight smell, and turn red with sulphuric or nitric acids, though Delpho curarine, their alkaloid, gives no colour with either acid. The extract of *D. bicolor* acts like curare. At first it increases the reflex action of the skin, but in two hours the muscles of the poisoned side only contract on direct stimulation, though on the unpoisoned side they are acted on by stimulating the sciatic nerve. *D. occidentale* at first acts like aconite, increasing all secretions, but later the muscles become insensible to any stimulation, either direct or through the nerves. *D. scopulorum* differs from the others, inasmuch as the nerve centres of the cord are greatly depressed, more than the nerve trunks or the motor ends. *Delphinium staphisagria* or *stavesacre* first stimulates the secreting organs and the nerve centres, then depresses, and at last paralyses both the nerve centres, the motor nerves and the muscles, and finally the nerve centres of the heart.

CENTRAL MIDWIVES' BOARD.

MEETING HELD MARCH 29TH, 1906.

The President, DR. CHAMPNEYS, in the Chair.

A LETTER was read by the Secretary from Dr. Meredith Young, M.O.H., Stockport, asking on behalf of the Incorporated Society of Medical Officers for information as to the proceedings of the Board, as far as they affected Local Supervising authorities.

The PRESIDENT thought it would be good to keep in touch with such bodies and suggested sending a report for the Society named to circulate as far as was necessary.

Sir WM. SINCLAIR hoped that as the desire had been

expressed by the officers of health of an important borough, such desire would be acceded to. The motion was therefore passed unanimously.

Dr. J. E. NEVINS of Liverpool, also wrote raising certain points as to the training of midwives and the construction of rules relating thereunto, particularly those concerning uterine douches, the use of drugs &c., as at present they might give opium or castor oil at their discretion.

The PRESIDENT thought answer should be returned that the Board gave no special procedure. The Liverpool people must use their own judgment.

Sir WM. SINCLAIR remarked that such questions proved what he had always said about incompetent teachers. The Board could not undertake to supply them with common sense.

It was agreed that answer should be sent as the President suggested.

Another letter from Dr. E. Walford, M.O.H., Cardiff, was read, asking the Board to make Cardiff a centre for examinations.

Sir WM. SINCLAIR objected to this, as it was necessary to keep down the number of centres, so why should one be held at the end of the earth, and in the Welsh tongue for the sake of a few women.

The matter of a new centre was referred to a standing committee, also that of a Welsh-speaking examiner, though at the meeting of examiners the latter motion had been carried by 7 to 5.

The question then arose of an official handbook for midwives, for which only 7 as against 17 had voted at the recent meeting of examiners.

Sir WM. SINCLAIR, who, at the previous Board meeting, had strongly urged the publication of such a book, said the objecting examiners ought to have stated their objections to the Board, or in the medical press. England was greatly behind the times in the matter of handbooks, and he should bring up the question again. The examiners had simply been asked to meet and prepare suggestions, yet they had even objected to having the President of the C.M.B. at their council and asked that neither he nor any member might again attend.

The Board then passed to the consideration of the Rules, as amended by a special committee. Among the points discussed was that of deleting "registered medical practitioner" with regard to signing of certificates.

MR. WARD COUSINS urged that it implied that practitioners had been present at each labour, which was not the case, they using medical students at their convenience, especially at night.

Sir WM. SINCLAIR agreed, saying it would be unpopular but wise to make the deletion. This was accordingly done.

Another point was the number and duration of lectures to midwives.

Sir WM. SINCLAIR gave it as his opinion that lectures ought to be more frequent, shorter, and no class to consist of more than 20. The room at Manchester was built to hold 120, and the fact of 120 illiterate women all probably going to sleep under the influence of a monotonous voice was pitiable.

Dr. PARKER YOUNG asked why a higher standard should be required for midwives than for medical students. Once a week was enough.

The PRESIDENT remarked that students had at least three lectures a week.

But Sir WM. Sinclair's motion was lost on being put to the vote. This member also wished to propose that women should first give proof of some elementary education. He had had women so ignorant that he was quite sure they ought never to have appeared, and would certainly never make intelligent midwives.

The PRESIDENT said as this was a very big question it would be better to consider it after the smaller amendments had been agreed to.

The words "suitable antiseptic lotion" for the eyes of the infants evoked a remark from

Dr. PARKER YOUNG that "warm water" would

be a better substitute as many antiseptics were unsafe in the unskilled hands of a woman who would probably use the same lint for both eyes. He knew of many cases also where one instrument had been used for two purposes.

Sir Wm. SINCLAIR added that women should either be thoroughly instructed in the use of appliances or struck off the roll for not knowing. It was a monstrous and unjustifiable proceeding to let uneducated women have any power, and it generally proved how inefficient the teaching had been.

At this stage, it being late, the Board had to adjourn, it being resolved to have an extra meeting to consider Sir Wm. Sinclair's motion as to illiterate women as candidates, and some other very important points such as the administration of drugs, &c.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS. ABROAD. FRANCE.

Paris, April 1st, 1906.

TREATMENT OF BULLET WOUNDS.

PROF. PAUL RECLUS, in one of his clinical lectures, spoke recently of the treatment of wounds produced by revolver shots, and said, "During the last five months we have received in our wards six cases of bullet wounds, and you have seen me proscribe all attempt to probe the wounds; I also refused to attempt to extract the balls, and you have understood my good reasons.

"Simple as it was successful, the doctrine of systematic abstention was gaining ground. Heretofore, the magnificent results of antisepsy and the discovery of the Röntgen rays diminished the interest in the question. Since the large incisions necessary to the discovery of the projectile had lost a great part of their gravity, and that erysipelas did not follow in the wake of the bistoury, the surgeon was able to operate with more or less impunity. Again, his researches were singularly facilitated by the radioscope, which directed the instrument to the precise spot where the foreign body lay.

"All this is true, yet I consider that the doctrine of systematic abstention is superior to interference. We will study for a moment the reasons for and against my attitude. First, to remove the projectile, an operation is necessary, and every operation is equivalent to a malady, slight or serious. Sometimes, also, it is necessary to chloroform the patient where the region is too extensive to be covered by injections of stovain or where the operator—and it is frequently the case—disdains local anaesthesia. The patient, consequently, has to face the dangers of chloroform, and in spite of intelligent antisepsy, infection is always possible, and, in any case, the cicatrix is much larger than the primary wound and the cure is less rapid.

"On the other hand, the inconvenience presented by systematic abstention is very slight, if it exists at all. In the immense majority of cases, the ball becomes encysted. As to the possibility of infection or suppurating fistulae kept up by the foreign body, such complications were, it is true, dreaded formerly when the wound was inoculated by repeated probing with soiled hands and instruments; but abstention proscribes those dangerous manoeuvres, and if any infection is observed it is provoked rather by fragments of the clothing drawn into the wound by the projectile, a rare accident in itself.

"Take the six cases I have mentioned. In four of them—a ball in the hand, in the thigh, in the thorax, and in the bones of the face a few antiseptic precautions were sufficient, and in a few days the patients left the hospital cured and the projectiles encysted. In the fifth, where the ball had drawn into the orifice a piece of clothing, we contented ourselves by making a small incision to remove the cloth, but took care to go no farther. You saw how easily the patient recovered.

"The sixth case was that of a young man who got a bullet into his left forefinger. When he arrived at the hospital the wound was already infected. We tried to arrest the progress of the infection by plunging the finger into a bath of warm oxygen water and succeeded for a few days, but it returned, and we decided on operating. After injecting stovain around the root of the finger ($\frac{1}{2}$ per cent. solution), and so rendering it insensible, we extracted the projectile.

"We only extract the projectile in very rare cases; where it is can be seen or felt, that is under the eye and hand of the surgeon, or where it becomes or might become an element of inconvenience (articulations), or where the ball or fragments of clothing provokes infection. But in all other cases I abstain, whether the ball has penetrated into the muscles or becomes incarcerated in a bone.

"I know of several persons who have lived very comfortably with a projectile for the last five, ten and twenty years. In some of them the bullet is lodged in a bone, the index, the internal condyle of the femur, the head of the tibia, the pelvis, the vertebrae and the maxilla. At an autopsy recently a revolver bullet was found by chance embedded in the frontal bone, where it had remained unnoticed for years.

"Where the projectile becomes dangerous it is when it cuts a tendon, a nerve, opens an artery or a vein and provokes hæmorrhage into a viscera as the brain, the lung, the liver or the spleen, or where it wounds a natural reservoir: stomach, intestine, bladder. In such cases an operation is imperative, not, however, to remove the foreign body, which in itself is harmless, but to repair the damage caused by its passage.

"To resume the foregoing, in spite of antisepsy and the Röntgen rays, which have rendered less dangerous and more easy the research of projectiles from firearms, I maintain that the best practice consists in systematic abstention from extraction."

ANTISEPTIC OINTMENT.

Through a printer's error, the formula of Prof. Reclus' antiseptic ointment which was given last week, is misleading and incorrect. It should be as follows:—

Antipyrin, 1 drachm;
Salol, $\frac{1}{2}$ drachm;
Boric acid, $\frac{1}{2}$ drachm;
Iodoform, 15 grs.;
Phenic acid, 15 grs.;
Corrosive sublimate, 2 grs.;
Vaseline, 7 ozs.

GERMANY.

Berlin, April 1st, 1906.

At the Society for Innere Medizin, Hr. Hans Kohn reported

A CASE OF VERY ADVANCED SYPHILIS OF THE CEREBRAL ARTERIES.

A bank official, æt. 26, was admitted into the Hospital "am Urban," with acute mania one evening and was transferred to the asylum the next morning. On being examined on admission into the asylum there were found to be slowing of the pulse, papillary stasis, and slight rise of temperature, symptoms therefore of an anatomical lesion of the brain. In the absence of all history or other indications, treatment by inunction was considered allowable, the result being that in about six weeks the patient had recovered. As, however, both then and subsequently he denied the possibility of any syphilitic infection, the chances had to be taken into account that his recovery was not due to the mercury, but that it was merely an accidental *post hoc*, the disease having been a mild acute encephalitis. Two years later the patient, who had been quite fit for work in the meantime, had an attack of complete right-sided hæmiplegia with loss of speech. The diagnosis and *lues cerebri* were now considered to be no longer doubtful, as it was very unlikely that any young man of thirty, with heart and kidneys sound, should suffer from any other disease of the brain than a syphilitic one. The treatment—*injection of hydrarg. salicyl. and pot. iod. internally*—brought about complete

recovery, and as the speaker now considered himself justified in doing he instituted an intermittent-anti-syphilitic course of treatment which was kept up until quite recently. In this way the patient retained his health and his capacity for work for nine years longer.

During later months he complained of giddiness, but still followed his employment. The first serious trouble occurred three weeks ago, a transient loss of consciousness, then on the following day there was twice paresis of the left arm with clouding of consciousness and disturbance of speech, which was remarkable on account of the participation on the part of the left arm; in the course of the night there was complete paralysis of the left arm and of the left facial, with disturbance of speech, but the power of writing still remained and power to understand words. There was also Cheyne-Stokes respiration with extreme tension of pulse. There had been traces of albumen in the urine about a year before, and this, along with the arterial tension, pointed to intestinal nephritis. The heart was enlarged. After fourteen days of deep coma and rapid but regular breathing, death took place.

The autopsy showed the most extreme arteriosclerosis and calcification of the cerebral arteries, in the smaller in the shape of nodules, in the larger so that they formed rigid tubes. There was a large extravasation of blood in the left peduncle that reached to the medullary layer forwards and posteriorly into the right half of the pons. Besides this, there was a cyst fully the size of a bean in the right temporal lobe. There were some larger and smaller prominences in the aorta, which on being cut into showed participation of the media and adventitia, on which stress had recently been laid in regard to arterial syphilis. Hypertrophy of the heart and commencing contracting kidney.

The speaker observed that although it was gratifying that treatment had so far served the patient as to prolong his life and render him fit for work for eleven years, yet it was depressing that regular specific treatment could not ward off the sad termination. That was depressing, but at the same time explainable when one considered that on the one hand an intermitting treatment has no certain preventive value and on the other no *restitutio ad integrum* followed the disappearance of a gummatous process in the arterial walls, but that non-elastic cicatricial tissue took the place of the gummatous infiltration. In Thomas' view the loss of elasticity resulted in a reactive growth in the walls, resulting in a thickening, a sclerosis. As further such sclerotic thickenings showed a disposition to retrogressive changes, such as a deposition of chalk the syphilis was still indirectly the cause of sclerosis and atheroma of the arteries. One could therefore, understand why a regular intermitting course of treatment should fail in severe cases to bring about complete recovery.

At the meeting of the Freie Vereinigung der Chirurgen of March 12th, Hr. Rinne spoke on the

OPERATIVE TREATMENT OF GENUINE EPILEPSY.

He showed a man, *æt.* 39, of healthy family, who had been healthy himself up to his eleventh year. Since then he had suffered from epilepsy, always commencing with right arm and becoming more frequent as time went on. The patient was quite incapable of work, he had paralysis of the right arm, his speech was affected, his memory lost, and he bid fair to become imbecile. After talking the matter over with Eulenburg, who had had the man in charge, first of all a bloody stretching of the brachial plexus was performed. After this the fits ceased for seven days,—*i.e.*, so long as the paresis resulting from the stretching lasted; they then returned. In 1894 trepanation was performed, the central convolution was exposed, and as nothing was found by electricity or otherwise the whole left central convolution for the thickness of two to three mm. was removed. The bony flap was then replaced as well as it could be.

For a week after the operation there was loss of consciousness and paralysis of the right arm and facial nerve. When consciousness returned the paralysis disappeared and the patient remained free from any

attack for seven months. Since then slight attacks had recurred at about monthly intervals and without loss of consciousness. The patient had been able to follow an independent occupation. He had occasional pains in the right arm, the temperature of which was always lower than that of the left. The Röntgen image showed a small slit in the skull, which served as a Kocher "safety ventilator."

AUSTRIA.

Vienna, April 1st, 1906.

SCLERODERMA.

NEURATH showed a girl, *æt.* 6, affected with scleroderma in the initial stage. Two months previous she had a swelling, which commenced without any attributable cause in the left parotid region. From this point the skin of the face grew thick, hard, and dark in colour; now this condition has extended to the hips and lower extremities, accompanied with oedema. The superficial integument of the skin seems to be less affected than the deeper structures, being loose and free, with the fine hair still present, notwithstanding the presence of deeper oedema.

Neurath remarked that this rarely appeared in young children, more particularly the oedematous form, which was rare, even in adults.

SARCOMA IN CEREBELLUM.

Rach exhibited a preparation taken from a child, *æt.* 8, who was apparently well up to four weeks before the exitus, when he had a fall on the back of his head, followed by vomiting and pain in the head.

He was received into hospital on February 3rd, and died the same night. The *post mortem* revealed a tumour in the left hemisphere of the cerebellum about the size of an apple, of a greyish-white colour, having a central necrosis. The rest of the cerebellar substance on the left side was infiltrated. In the thorax and lumbar regions of the cord a form of metastasis about the size of peas were to be found both posteriorly and anteriorly.

The microscope proved these to be polymorphic-celled, and vascular sarcoma.

Schlesinger expressed surprise that a fall would develop such a diffuse form of multiple sarcoma in such a brief period. He did not know of another case on record with such convincing results of multiple sarcoma in so short a time. From a forensic point of view, it is important and worthy of careful consideration.

SODIUM CHLORIDE IN DROPSY.

Gruner next gave the Gesellschaft a history of his experiments with common salt, and its power of retention in the case of dropsy. Chloride passing through the kidneys disturbs the osmotic function, and produces a pathological retention of water in the body which leads to oedema.

His experiments were carried out on children with non-chloride diet, which had the effect of relieving oedema when it existed. He experimented on a cardiac case—incompensatory vitium with oedema; two acute and two chronic cases of parenchymatous and interstitial nephritis, along with two healthy children.

At first 10 grammes of salt was given daily. The body weight increased in proportion to the retention of water, but the nephritic cases more rapidly than any of the others. Dropsy was easily induced in these cases, and not so easily relieved when the non-chloride diet was commenced. In the interstitial form there was an increase in the elimination of chloride, but a corresponding increase in the weight, which was evidently a retention of the *Chlorurée sèche* of Ambard. This was soon relieved by a non-chloride diet. It would seem that the chloride disturbance is not always constant in the osmotic equilibrium. In a healthy 2½ months child he could suddenly raise the weight of the child by the retention of the water. In many conditions he assumed the kidneys were not able to eliminate the normal amount of chloride, which, suddenly accumulating in the body, led to water retention, and finally oedema.

Theoretically, he considered this an important clinical advance in the treatment of many diseases of dropsy, such as nephritic and cardiac, where a non-chloride diet was indicated.

MANITOBA.

THE QUESTION OF COLONIAL DEGREES AND DIPLOMAS IN CANADA AND JAMAICA.

THE Council of the College of Physicians and Surgeons of Manitoba are petitioning the Legislative Council of the Province to amend their Act in certain particulars. Among these is the following: "The clause defining those entitled to Registration under the Medical Act is sought to be amended by giving the Council the option of refusing registration (without examination) to any person who seeks registration solely on the ground of his being registered in Great Britain." The reason given for this interesting amendment is sufficiently naive to command our admiration when we consider that the medical education imparted at the Medical College affiliated with the University of Manitoba scarcely soars above mediocrity. Further, the examinations of the University are confined to simply a written one, and that in many subjects a dozen or more questions are set, so that he must be a weak candidate indeed, who cannot pick out among so many questions enough to get the fifty per cent, of marks to pass. Here is the reason as set forth by the Council of the College of Physicians and Surgeons of Manitoba which should make the members of the General Medical Council of Medical Education and Registration in Great Britain rub their eyes and ask, "What next?" "Under the Act, as it is at present, the Council cannot legally refuse to register any such person, notwithstanding the fact that some of the licensing bodies whose qualifications are acceptable by the General Medical Council in Great Britain, exact a standard notoriously lower than that demanded by the Manitoba Council from students educated in this Province and in the other Provinces of the Dominion." While this effort is being made in Manitoba to protect the Province from the inroad of men who have qualified on a "standard notoriously lower" than the Manitoba standard, a discussion is going on in Jamaica with regard to the admission of Canadian medical graduates to practise in the Island on the score of their unfitness. It appears from Jamaica papers to hand that Dr. Ker, the Superintending Medical officer sent out by the Colonial Office, has it is presumed, the sanction of the governor to bring forward a motion to enable Canadian graduates to practise in Jamaica on the same footing as British graduates. I quote from a leading article in one of the leading papers of the Island of recent date. "At one time," says the article, "Canadian medical graduates were allowed to practise in Jamaica on the same footing as English, Irish and Scottish graduates; what was the result? To use a colloquial expression, most of them 'made a hash of it.' So notoriously inefficient did some of these imported medicos prove themselves, and so much dissatisfaction was created by their work that the concession was withdrawn by Law 28 of 1885, which enacted that only holders of British diplomas, or graduates from the Colonies and foreign nations who passed an examination before the local Medical Councils should be allowed to practise their profession in Jamaica. Of course, it may be said that the standard of Canadian degrees is now much higher than it was thirty years ago. The truth of this may be admitted at once, but that does not settle the matter finally. For it must be known to the Superintending medical officer and the ruling officials of the colony that, within recent years, several Canadian graduates have failed to pass the very elementary examination which is set by our Medical Council." The article winds up by pleading delay in pronouncing judgment on the motion.

It is a strange coincidence that a discussion on almost the same lines should be going on in two distant colonies with this difference that in Manitoba the protective spirit is in favour of the graduates of the

Manitoba University, who dread that the increase of immigration may bring along British graduates; in Jamaica the object is to protect the people from incompetent practitioners. It would doubtless be of advantage to the General Medical Council in England if the Council of the College of Physicians and Surgeons of Manitoba would state specifically the British qualifying bodies with a standard "notoriously" lower than theirs.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

GLASGOW.

OPENING OF A NEW INFECTIOUS DISEASES HOSPITAL.—On Friday last, March 30th, 1906, the Lord Provost of Glasgow opened a reception house in Baird Street, for contact cases. The energetic convener of the Health Committee, Bailie W. F. Anderson, gave a sketch of the building, stating that it consisted really of three different divisions, each of which could be completed to shut off from its neighbours, as occasion might arise. A special feature of the new institution is the provision of a number of rooms, where a whole family can be accommodated. There are dormitories for men, and dormitories for women. There is accommodation for 190 adults, exclusive of the staff. The total cost, including furnishings, is estimated at about £11,000, while the cost per adult bed will be about £57.

GLASGOW EASTERN MEDICAL SOCIETY.—At a meeting of the above Society, held on Wednesday, March 21st, Dr. Leonard Findley gave a very interesting and instructive demonstration by means of the microscope and the lantern on the various abnormalities of the red and white blood corpuscles, discussing briefly their significance. Dr. John Dunn showed microscopic specimens, illustrating the different stages of the plasmodium in the tertian, and malignant forms of malarial fever.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—Our correspondent has furnished a report of an interesting meeting of this Society held on Wednesday last, which will be found in another column, under the heading of "Transactions of Societies."

BELFAST.

QUEEN'S COLLEGE.—Dr. James Wilson has been elected Riddel demonstrator in pathology and bacteriology, in the room of Dr. Wm. Mair, resigned. Dr. Wilson had a most distinguished career at college, and has just vacated the Dunville Studentship. He has for some time been working in the pathological laboratories under Professor Symmers. The plans for the additional buildings (which gave rise to several questions in Parliament lately) are now being settled. They include the completion of the chemical buildings, the enlargement of the physiological and pathological laboratories, and the provision of more lecture rooms. These additions will be an immense boon to professors, and students alike, as the present rooms are quite too crowded.

ROYAL VICTORIA HOSPITAL.—The annual meeting of this hospital was held last week, and the medical report, read by Dr. McKisack, showed increased work all round. The internal patients numbered 3,018, and the external 25,967. There were 1,117 surgical operations, with 50 deaths after them, a mortality of 4.4 per cent. Excluding the cases moribund on admission the mortality in the medical wards was 5.30 per cent, and in the surgical 2.8 per cent., giving a general average of 3.7 per cent in the hospital. New beds to the number of 32 were opened last April, but the accommodation is still quite insufficient for the cases applying for admission.

ULSTER MEDICAL SOCIETY.

ADDRESS TO THE LORD LIEUTENANT.—On the occasion of the visit of His Excellency the Lord Lieutenant to Belfast last week, an address was presented to him by the Ulster Medical Society. The deputation present-

ing it consisted of Dr. Wm. Calwell (President), Professor Byers, Drs. Dempsey, Davison, McCaw, and Thos. Houston (hon. sec.).

TUGHAN v. DARNELL.—A special joint meeting of this Society and of the Ulster Branch of the British Medical Association was held in the Medical Institute, Belfast, on Thursday evening, March 29th, to consider this case. The question of an appeal against the decision in the late trial was discussed at length, and the bearing of the learned judge's interpretation of the law as regards negligence on the members of the profession generally. It was agreed to adjourn the meeting till counsel's opinion could be obtained on certain points. The question of raising a fund to assist in defraying the expenses of the three trials was also postponed.

LETTER TO THE EDITOR

EYE-STRAIN AND IMPERFECT LIGHT.

To the Editor of the MEDICAL PRESS and CIRCULAR.

SIR,—I have often wondered why reading in an imperfect light tired the eyes. Of course, it is easy to adduce as a reason that "it is a much greater strain reading by candle light than by daylight," but that, after all is only re-stating the same fact in different words. Moreover, I do not remember having seen anything beyond the mere statement in books on refraction—that is to say, anything that explains exactly where the strain comes in.

It occurs to me that a photographic experience will serve the purpose. When we wish to photograph a view comprising near as well as distant objects and desire all of them to be in focus, the plan is to make use of a very small diaphragm. Now, when we read in a good light the pupil is of course contracted, and cuts off the marginal rays, so that very little effort of accommodation is necessary and we read with comfort. In twilight, however, the pupil is naturally dilated, and it becomes necessary to focus with greater precision just as with a camera when we employ a large aperture. I take it that it is the constant effort to maintain the exact focus that proves so fatiguing, and of course the larger the type the less is the strain on the accommodation.

The strain is exaggerated by the fact that one is tempted to bring the object nearer to the eye when the page is inadequately illuminated, thus adding to the focal effort and throwing more work on the apparatus of convergence.

Yours truly,
ALFRED S. GUBB, M.D.

Mustapha Supérieur,
Algiers, March 31st, 1906.

OBITUARY.

LIONEL SMITH BEALE, F.R.S.

We regret to announce the death of a distinguished member of the medical profession in Dr. Lionel Beale, who died on March 26th, at the age of seventy-eight years. He was educated medically at King's College, and was connected with that institution for more than forty-three years. He qualified as M.B. of London University in 1851, became a member of the London College of Physicians in 1856, and a Fellow in 1859. In 1871 he was appointed Baly medallist of the Royal College of Physicians, of which body he was Lumelian Lecturer in 1875. In 1865 he was chosen Croonian Lecturer to the Royal Society. At King's College he held many important posts, the chief being that of consulting physician, and on his retirement that of Emeritus Professor of the Principles and Practice of Medicine. From his student days Dr. Beale was an ardent worker with the microscope, and perhaps the best known of his many works is "The Microscope in Medicine," a large volume that reached a fourth edition. Dr. Beale was an authority on protoplasm, and made many valuable contributions to medical

science and medical literature. As a teacher and as a man of science, he was strenuous, untiring, and full of high purpose. His life has indeed been well spent in the service of a noble profession. His son, Mr. Peyton Beale, is surgeon of King's College and of the Great Northern Central Hospital.

MR. WM. R. H. STEWART, F.R.C.S.ED.

WILLIAM ROBERT HENRY STEWART, F.R.C.S.ED., of Wilbet Crofton, Orpington, and 42, Devonshire Street, London, W., who died on March 7th, 1906, aged 54, was the eldest son of the late William Edward Stewart, of 16, Harley Street, W. Studied at the University College Medical School, and was admitted a Member of the Royal College of Surgeons, England, in 1874, a Licentiate of the Royal College of Physicians, Edin., and of the Society of Apothecaries in 1876, and a Fellow of the Royal College of Surgeons, Edin., 1878. Mr. Stewart devoted much time and study to affections of the ear and throat, and had been surgeon and surgeon-in-charge in the throat and ear department of the North-West London Hospital, and Surgeon to the Throat Hospital, Golden Square, and to other public institutions in London. He was surgeon-in-charge of the throat and ear department of the Great Northern Central Hospital, consulting surgeon to the London Throat Hospital, and a member of various societies. Mr. Stewart was the author of several works on professional subjects.

DR. THOS. EVANS, M.D., NEWQUAY.

DR. EVANS, who died last week at the age of 65, obtained the degree of doctor of medicine (Edinburgh) in 1865. Whilst studying there he contracted typhus fever, on which, towards the close of his university career he wrote a thesis which won for him the warm approbation of his professor. He left the university for Ystradgynlais, and then became house surgeon of Portsmouth Hospital. Obtaining the appointment some years later of medical officer of health for the lower division of the Aberayron Union, he settled down to practise at Newquay, where he was greatly respected. He was twice married, and leaves a widow and five children.

DR. LOGAN, WHITEHEAD, CO. ANTRIM.

DR. WILLIAM LOGAN, who died last week at his home at Whitehead, was well known in the North of Ireland, and greatly respected. He graduated at St. Andrews in 1862, and practised in Belfast, and then in England, but some years ago his health began to fail, and he retired to a country cottage in a lovely position overlooking Belfast Lough. Dr. Logan was never inclined to appear much in public, or take part in public affairs, but to all who knew him he endeared himself by his unflinching kindness and geniality. His children, two sons and a daughter, have all entered their father's profession.

NEW PREPARATIONS.

WELLCOME BRAND PILOCARPINE NITRATE.

CERTAIN recent statements in pharmaceutical and analytical reports have been to the effect that it is extremely difficult to obtain essentially pure Pilocarpine. We know that the standards of purity adopted by both the British Pharmacopœia and United States Pharmacopœia are below the standard generally referred to, viz.:—melting point of 174–178° is that proposed some years ago by Dr. Jowett. On the other hand it has been shown that the melting points of commercial specimens range from 162–168°. In the course of the exhaustive enquiry on the Jaborandi Alkaloids conducted in the Wellcome Chemical Research Laboratories, the necessity of an absolutely pure Pilocarpine Nitrate was demonstrated, and it was also shown that the associated alkaloids differed considerably in physiological activity. In connection with these researches the manufacture of Pilocarpine salts of the highest degree of purity was

undertaken by Burroughs Wellcome and Co., and in order to demonstrate the purity of their product and the fact that none is issued under the above standard, the melting point of the batch is indicated on the label of each "Wellcome" brand package. This melting point is 175-176°, a figure which represents chemically pure Pilocarpine Nitrate.

HÆMOSTASIN.

MESSRS. BURGOVNE, BURBIDGES AND CO. have introduced a new and trustworthy preparation of suprarenal gland under the name of "hæmostasin." It is made according to the method of Aldrich and Takamine, who first produced the active substance of the gland in the form of crystals. In this way many of the technical difficulties of isolating and of preserving the active principle are overcome. Besides its use as hæmostatica, this drug has an important application in urogenital practice. For minor operations it acts well as a pre-operative ischæmic, and can be combined with cocaine so as to procure in addition local anæsthesia. Hæmostasin also acts as a valuable cardiac stimulant. An excellent short account of the history, preparations and uses of hæmostasin is published by Messrs. Burgovne, Burbidges and Co.

CHIVERS' PRESERVED FRUITS.

THE cry for home productions could hardly be better directed than in the case of fruit, vegetable and dairy produce. In the case of fruit, we are glad to see that the well-known firm of Messrs. Chivers and Son have come to the rescue with a new process in which English fruit is preserved in tins. This trade in foreign tinned fruits is enormous, but there is no fruit in the world to equal the delicate flavour and attractiveness of that grown in our own country. Messrs. Chivers own 2,000 acres in Cambridgeshire, where they grow the finest fruit in large quantities. By a process of their own they preserve the greengages, raspberries, and what not in such a way that each keeps its particular flavour and remains sound and wholesome for an indefinite number of years. The samples we have examined in our opinion represent the perfection of preserved fresh fruit. We congratulate this enterprising firm on having added materially to the resources of a wholesome and important branch of agriculture.

REVIEWS OF BOOKS.

CABOT ON PHYSICAL DIAGNOSIS (a)

THE object of this volume, as the preface informs us, is "to present an account of the diagnostic methods and processes needed by competent practitioners of the present day." It differs, we are told, from similar books in that no attempt is made to describe technical processes with which the writer is not familiar, and in that no space is given to description of tests which he believes to be useless. We congratulate the author on his candour and courage, and might add that it differs also—or rather in consequence—in being practical and readable. We are not, in fact, acquainted with any book which gives in so pleasant a form all the essentials of the diagnostic art, while eliminating at the same time those methods which, however useful, must remain more as limited specialities than as aids to the general practitioner. It is, we presume, to the qualified and practising physician that the writer addresses himself, and it is such, no doubt, who will derive most value from a perusal of the book, but at the same time we express the hearty wish that every medical student should be compelled to learn and practise the more elementary methods described before admitting him to hospital lectures. Once they were learned the lectures would have a meaning and the time and patience of both teachers and taught would

be saved. As matters at present are, many a student obtains his qualification without having any real knowledge of the physical principles underlying the methods of examination he has learned, and hence is liable to go hopelessly astray when confronted with any unusual case. This results not from any real difficulty in the subject, but rather from the lack of any systematic teaching of it. The student learns to recognize disease by certain signs, but does not grasp the meaning of those signs. If now at the beginning of his course he was compelled to recognize the body as a physical machine, subject, more or less, to ordinary physical laws, this trouble would be obviated, and more time would be available for the all-important study and appreciation of symptoms. These remarks may perhaps appear out of place in the review of a book, but as they embody our fixed opinions with reference to the importance of an early study of the subject treated of in the volume they may be allowed to stand.

While all sections of the book show considerable merit, most praise is, we think, due to the section which deals with the examination of the chest. We are in agreement with the author that percussion is the most difficult of all the arts of examination to acquire, and that none is so seldom thoroughly learned. His own methods appear to us in general to be sound, though to descend to details we entirely disagree in his estimate of the value of the area of deep cardiac dulness. Our own opinion is that its value is nil, and we have almost entirely given up the attempt to map it out, though we, of course, admit that many observers place considerable reliance upon it as a diagnostic sign. On page 264, we find Osler quoted as defining palpitation as "irregular or forcible heart action perceptible to the individual." It is surely unnecessary to quote anybody in support of this definition nowadays, but if a name is wanted the writer might we think go further back in his search of authority. On page 291, we are told that in cases of doubtful diagnosis between aneurism and empyema necessitatis, "it is perfectly safe to insert a hollow needle." However safe this procedure may be in very careful hands, we can hardly believe that it is one to advise in a text-book. Though many aneurisms may be punctured without danger, there are some in which puncture would be attended by a fatal result, and so we think that the reader should be informed of the dangers and advised rather to endeavour to perfect his diagnosis by other means. We must in all cases endeavour to prevent medicine becoming like surgery, a pursuit in which diagnosis is made by operation. There are a few other points which we might find fault with; for example, we do not ourselves perform the nitric acid test for albumen in a wine glass, but these matters are very small, and, on the whole, we have nothing but praise for the work.

The illustrations are numerous, and, for the most part good. We could hardly have believed that the picture on page 148 was required, but doubtless there are some to whom it will appeal; on page 173, the aortic valve is figured as being at a higher level than the pulmonary; and on page 429 a trivial illustration is introduced. The great majority of the figures are, however, practical, and illustrate important clinical conditions. They greatly add to the appearance of the book, though a dash of colour in the blood pictures would make them more attractive.

THE CLINICAL SOCIETY'S TRANSACTIONS. (a)

ONCE again the Transactions of the Clinical Society make their appearance in their familiar garb to remind us of the good work done by the society and to bear witness to its continued vitality. The volume does not differ in any respects from its predecessors, consisting as it does, of a series of short papers upon cases of interest, and of notes upon clinical cases which were exhibited at the various meetings throughout the session. The latter number fifty-one in all, and as

(a) "Physical Diagnosis." By Richard C. Cabot, M.D., Instructor in Medicine in Harvard University. Third Edition, Revised and Enlarged. Plates 5; figures 240. London: Baillière Tindall and Cox, 1906. Price 10s. 6d. net.

(a) "Transactions of the Clinical Society of London, Vol. 33. London Longmans, Green and Co. 1905.

they are picked, we presume, from a very much larger number of exhibits they throw an instructive light upon the numbers of rare and interesting cases which pass through the general hospitals of London within the year.

The present volume opens with an address by the President, Dr. Frederick Taylor, in which he deprecates the fact that therapeutics have not kept pace with the extension of our etiological and pathological knowledge, and urges the members to pay more attention to the therapeutical side of their cases, when exhibiting and reporting them. With this exhortation we are only in partial agreement, for while admitting the crying need of an extension of therapeutical knowledge, we believe that such an extension must logically follow, and not accompany the increase in our pathological and etiological data. While, therefore, the patients of the present day may perhaps suffer through our ignorance, we believe that the patients of the future will gain through our methods of seeking knowledge, and that when the time is ripe therapeutics will once again come to the fore, but as a rational science and not as an empirical application of often ill-founded and of single observations.

The communications which constitute the bulk of the Transactions are thirty-three in number, and it is no exaggeration to state that each one of them is of unusual interest. The collection as a whole forms in fact one of the most readable books of this nature that we know. The rules of the society forbid lengthy articles, and for the most part confine their contributors to the record of single clinical cases. The result is that each communication is in the form of a graphic clinical picture, tersely worded and clear, and devoid of the long historical and theoretical discourses which so often labour similar records in the various journals. From among so many papers, however, we can only select a few for special notice. On the medical side, the paper by Dr. Box on "The Crises of Posterior Basic Leptomeningitis calls attention to the pyæmic character which a chronic non-suppurative meningitis may assume, and also to the length of time that these cases may last. Five cases are reported, one of which lived for nearly four months after the initial symptoms, and presented during that time a daily rise of temperature to from 102-104° F., followed in a few hours by a fall to subnormal. The autopsy in each case showed slight posterior basic meningitis and chronic hydrocephalus. We regret that a more careful bacteriological examination of all of these cases was not made, as we believe that some of them would have proved to be chronic infections by the colon bacillus.

Dr. Ewart does good service in calling attention to what he terms "soft valve" mitral stenosis, in which no murmur is audible, and Dr. Hale White records an interesting case of "Acute Rheumatoid Arthritis," while the whole subject of arthritis deformans is discussed by Abrahams in the immediately succeeding paper. Among the surgical communications the most striking is the report by Harris and Low, of "The Cure of Infantile Paralysis of the Shoulder by Nerve Grafting." The essential steps in the operation consist of determining by experiment, after exposure of the brachial plexus, what trunks are degenerated, and then grafting the distal end of such trunks into healthy nerves. The results have on the whole been most successful and reflect much credit on the operators. The paper by Barker on the "Condition of the Small Intestine some Years after Extensive Enterectomies" is of real physiological importance, though, perhaps of minor interest from a practical point of view; while as a curiosity amongst the complications or sequelæ of appendicitis we find recorded by Weber a case of "Localised Flushing and Sweating of the Cheek." Of the other papers we need only mention "Urinary Paraplegia" (p. 80), "Intermittent Hydrops of the Joints" (p. 147), and "A Case of Kaposi's Disease" (p. 238), while advising our readers to purchase the volume and enjoy it for themselves.

"Food and Diet" and National Health.

THE Hon. Sydney Holland presided on Wednesday last, at the rooms of the Medico-Chirurgical Society, over an interesting lecture delivered by Dr. Robert Hutchison on "Food and Diet." The lecture was the first of a series of three, being delivered under the auspices of the National Health Society on Wednesdays at 5 p.m. They are principally for the Members and Students of the Society, many of whom are training to become women sanitary inspectors, &c., but visitors can obtain tickets at a nominal charge of 1s. per lecture, by applying to the Secretary, at 53, Berners Street, Oxford Street, London, W. On Wednesday, March 28th, Prof. G. Sims Woodhead lectures on "Temperance," Sir Thomas Barlow, Bart., M.D., K.C.V.O., presiding; on April 4th, Sir Dyce Duckworth, M.D., LL.D., lectures on "Dust," when Dr. J. F. W. Tatham presides. The Chairman in introducing Dr. Hutchison said that no one was better qualified or able to lecture on "Food and Diet" than he, as he had taken and analysed every patent medicine and food which had been brought out. The Lecturer said that what was wanted was to know which foods for a particular person were most suited to him. Hard and fast rules were impossible. The principal need was the repair of the tissue of the body and the supply of energy to it. **Trinity College, Dublin.**

The following candidates passed in the subjects indicated during Hilary Term, 1906:—

Final Examination in Medicine—Part I.—Thomas O. Graham (passed on high marks), Francis W. H. Bigley, Cecil T. Conyngnam, Henry D. Woodroffe, Ernest C. Crawford, Charles G. Sherlock, Arthur E. Knapp, Albert T. J. McCreery, Francis O'B. Kennedy, Wilfred L. Hogan, Henry B. Leech, John A. Hartley, Joseph C. Ridgway, Wallace D. Mitchell, and George H. Slack.

Intermediate Medical Examination—Part II.—William Pearson, Johannes C. Pretorius, Robert E. Wright, William E. Hopkins, John A. W. Ponton (the foregoing five passed on high marks), William S. Thacker, David J. Miller, Dixie P. Clement, James F. Clarke, Wilfred J. Dunn, Thomas P. Dowley, Alfred H. Smith, James C. C. Hogan, Gordon A. Jackson, John H. Morton, Thomas P. S. Eves, Norman P. Jewell, Allan T. Powell, Julian B. Jones, James R. Yourell, Ernest C. Lambkin, Oliver Gogarty, Edmund H. Sheehan, Alexander S. M. Winder, William Knapp, Frank R. Seymour.

Final Examination in Medicine—Part II.—Samuel G. S. Houghton, Gustav W. Thompson, John D. Sands (the foregoing three passed on high marks), Robert A. Askins, John C. P. Beatty, Basil G. Brooke, Thomas H. Peyton, Francis Casement, Francis Coppinger, George Dougan, George G. Vickery, Ralph S. Oldham, Edward Gibbon.

Conjoint Examinations in Ireland.

CANDIDATES have passed the First Professional (March) Examination, as undernoted:—Messrs. P. White (with Honours), S. Campbell, R. Charles, D. F. Curran, J. Donoghue, J. W. Flood, F. R. Jones, L. C. King, J. Mitchell, T. Murray, J. T. MacDonnell, C. McDonnell, M. O'Brien, P. O'Farrell, W. R. O'Keefe, G. Sheehan, and R. A. Wright.

THE annual general meeting of the Medical Graduates' College and Polyclinic was held at 22, Chenies Street, London, on March 23rd, the chair being occupied by Dr. C. Theodore Williams, who, in moving the adoption of the report and balance sheet, said that though the College was spending less money than formerly, it was nevertheless making about the same. The number of members was satisfactory, and the number of temporary subscribers was large. He referred with pride to the lectures delivered during the last year dealing with surgery, medicine, and all specialities. A new departure was the formation of tutorial classes started by Captain Pinch. The following five new members of council were elected:—Dr. H. Campbell, Dr. W. Ewart, Dr. E. N. Féré, Dr. Dundas Grant, and Dr. R. Purdie.

MEDICAL NEWS IN BRIEF.

Action Against a Cork Medical Man.

AN action of considerable importance to the medical profession was heard at the recent Cork Assizes before the Lord Chief Justice. A midwife of the name of Harvey attended a lady in her confinement, which passed off normally. A couple of days later the midwife went to another case, in which, according to the evidence, the body was born in a state of decomposition, and the mother subsequently died of sepsis. For several days the nurse attended both cases, and after she had ceased attendance on the first the infant developed an acute suppurative omphalitis, of which it subsequently died. Two days prior to its death, when it was in a moribund condition, it was brought to Dr. Dalton, the defendant in the action. He recognised that it was dying, and in a very serious condition, and amongst other measures ordered hydrarg. cum Creta in half-grain doses with the object of producing its purgative effect and of stimulating the action of the liver. On the child's death, he gave a certificate of death from "spreading cellulitis." The parents of the infant asked what this term meant, and Dr. Dalton replied that it meant "blood-poisoning." The father immediately connected the death of his infant with the death of the former patient of the nurse who had died of sepsis, and said that the nurse had communicated the infection and that he would take an action against her. He also went to the public health authorities and acquainted them of the case, with the result that they sent for the nurses's clothes to have them sterilised. The nurse considered that this was detrimental to her practice, and brought an action for slander against Dr. Dalton, the parents of the dead child, and two relatives. The case proved a long one, and cannot be fully discussed. The chief point relied upon by the plaintiff was that Dr. Dalton had first made a diagnosis of syphilis, which diagnosis, actuated by spite against the nurse because she had advised patients of his to seek advice elsewhere, he had changed to blood-poisoning, and that in fact the child did die of syphilis. The reason given for saying that Dr. Dalton had diagnosed syphilis was that he had administered mercury. This notion was, of course, easily combated, and the jury returned a verdict for the defendant on all points. We congratulate Dr. Dalton on the result of the case because it appears to us that he acted throughout in a proper and straightforward manner. He was confronted at the same time with an angry father and with a nurse who, from what transpired at the trial, was not as careful as she ought to have been. Each of them expressed the desire to take legal proceedings against the other and Dr. Dalton endeavoured to arrange matters amicably. So well did he try to do this, that the only occasion on which he could have been proved to say anything reflecting upon the nurse was in his own study to the nurse and her mother alone, and at a time when he was trying to give them both good advice. If the well-meant efforts of medical men are to be used as an occasion for promoting a slander action, it will have the effect of rendering them very careful as to the persons on whose behalf they make such efforts.

The Drug Contracts Question in Ireland.

MR. FIELD, M.P., asked the Chief Secretary for Ireland in the House of Commons on the 27th ult., whether he was aware that, owing to the recent action of the Local Government Board, about three-fourths of the tenders for drugs and medicines to Irish Unions are necessarily supplied by English firms of wholesale druggists; would he say whether Irish firms were allowed to tender for similar contracts in England, and whether he would take the necessary steps to enable Irish firms to tender for supplies on equal terms in both countries?—Mr. Bryce replied that one-

third of the drug contracts, and not three-fourths was obtained by an English firm last year. As regards the latter part of the question, it must be remembered that one-half of the cost of these medicines is defrayed from public funds. It is the duty of the Guardians to obtain the best return for the money of the ratepayers, whose trustees they are; and similarly it is incumbent on the Local Government Board to see that no unnecessary charge is placed on public funds. Moreover, any attempt to confine tenders to Irish firms might have the effect of prejudicing Irish tenders for various articles from being accepted in England. So far as the Local Government Board for Ireland are aware, there is nothing to prevent Irish firms from tendering for similar contracts in England upon equal terms with English firms.

The International Congress of Medicine at Lisbon.

WE are informed by the National Committee for Great Britain and Ireland that the London, Brighton and South Coast Railway Company gives notice that it will issue return tickets from London to Irun to members of the International Congress of Medicine, their wives and children. The tickets are available for sixty days *via* Dieppe, Paris, and Bordeaux at fares, £5 15s. 5d. first-class; and £4 18s. second-class. They can be obtained at the Victoria and London Bridge Stations of the L. B. & S. C. R., the only formality necessary being the presentation of the *carte d'identité*.

The South Eastern and Chatham Railway Company has arranged, conjointly with the French railways, to issue return tickets from London to Irun at the greatly reduced rates of £6 13s. first class and £4 12s. second class, for members who propose to travel overland to Lisbon. The tickets will be available *via* Dover and Calais or by Folkestone and Boulogne, but members are advised very strongly to take the 10 a.m. service from Victoria *via* Folkestone and Boulogne, as that service is the least crowded and reaches Paris at 6.4 p.m. in ample time to dine before continuing the journey by the 8.7 p.m. express. This train reaches Irun at 8.50 a.m. on the following morning. The tickets are available for 45 days, and will also be issued to the wives and children of members, but not to other relatives. They can only be obtained at the Victoria S.E. and C.R. on production of the Membership certificates, from April 1st onwards.

Medical Salaries in Wales.

THE Guardians of the Bangor and Beaumaris Union, having lost their workhouse medical officer, have advertised for a successor, fixing the salary at £50, out of which he will have to supply the drugs required. This remuneration naturally is not considered enough for the importance of the post and the duties involved, and last week a meeting of local medical men was held when the following resolution was passed:—

"That this meeting of the medical men of Bangor resolves that the salary of £50 offered by the guardians of the Bangor and Beaumaris Union for the post of workhouse medical officer is totally inadequate for the services demanded, and that after the passing of this resolution, any medical practitioner applying for the post at a smaller salary than £70 per annum will be guilty of disloyalty to his profession."

Death by Misadventure.

AN unfortunate occurrence at Caerphilly, Wales, resulting in the death of a medical man from an overdose of chloral, took place last week; and at an inquest held on Friday, the jury returned a verdict of "Death by Misadventure," after evidence had been given that the deceased, Mr. Chas. Dolman, L.R.C.P.Ed., was in the habit of taking drugs for insomnia, and a bottle of chloral-hydrate was found in the room.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

Recent Surgical Methods in the Treatment of Certain Forms of Paralysis.—Tubby (*British Medical Journal*, March 3rd, 1906) discusses the treatment of the deformities arising from anterior poliomyelitis, spastic paralysis, ischæmic paralysis, and some traumatic lesions of nerves, by the various methods of tendon and muscle transplantation, and by nerve anastomosis. The author describes a number of operations he performed. A case of paralytic equinovaglus associated with paralysis of the tibialis anticus was treated by grafting a strip of the extensor proprius pollicis tendon into the tibialis anticus, and the two outer tendons of the extensor communis digitorum were severed and attached to the periosteum of the internal cuneiform bone. The tendo Achillis and plantar fascia were divided at the same time. The foot was put up at right angles and somewhat inverted, in Scarpa's shoe for six weeks, and after the wound had healed massage was applied to the grafted muscles. The result was excellent. The outer border of the foot on standing pressed firmly on the ground, and the inner border was raised. There was a good arch formed with no eversion. A girl, æt. 13, suffering from paralysis of the extensors of the thigh, causing the leg to hang at right angles at the knee, was treated by grafting the semi-membranosus tendon into the extensor cruris. A useful limb resulted. In the upper extremity the author has operated for the relief of pronator and flexor spasm of the fore-arm in spastic paraplegia, by detaching the tendon of insertion of the pronator radii teres, passing it through the interosseous membrane, and fixing it to the outer side of the radius, so that it may assist in supination. A gentleman, æt. 26, with a contracted and entirely useless spastic hand, was so much improved by operative treatment that he was able to use the hand in writing. In this case the carpal flexors were divided, their tendons lengthened by means of silk attachments, and then transferred to the extensor surfaces of bases of the second and fifth metatarsal bones. Subsequently the digital and thumb flexors were lengthened at the wrist. In discussing nerve anastomosis the author describes a case of traumatic facial paralysis. The distal end of the facial nerve was inserted by lateral implantation deeply into the hypoglossal nerve. A week after the operation the palpebral fissure was lessened in size, and the eye could be temporarily closed. In less than four months the patient had recovered very fair movement of the facial muscles, with only slight impairment of speech, due to interference with the hypoglossal nerve. Nerve grafting has also been used for the treatment of infantile paralysis. In a case of paralytic talipes calcaneus grafting of the nerves to the soleus and gastrocnemius from the internal popliteal to the external popliteal was followed by recovery. S.

A Preliminary Report on a Study of Fractures of the Head of the Radius, with Special References to its Frequency, and to Fractures of the Neck of the Radius.—Thomas (*St. Louis Med. and Surg. Journ.*, Jan., 1906), calls attention to the difficulties in diagnosis, and the uncertainties of prognosis, of this variety of fracture at the elbow-joint. The literature on the subject is scanty. The fracture is usually caused by a fall on the hand. The head of the radius is broken off by striking against the capitellum of the humerus, the fracture extending through the neck of the radius. Clinically in these cases the head of the radius is found to move with the shaft. There is no crepitus or deformity. The principal signs are pain at the elbow and limitation of movement, more particularly of

pronation and supination. The fracture may easily be missed in a skiagram if an antero-posterior view alone is taken, as the rays then pass at right angles to the line of fracture. A lateral view usually shows the fracture clearly. Fracture of the head and neck of the radius are frequently associated with posterior dislocation of both bones of the forearm at the elbow. This condition is liable to be overlooked in skiagrams, as the radial head is obscured by the ulna and condyles of the humerus. Skiagraphic statistics are important in establishing the frequency of this fracture, and also show that fracture of the head and neck are essentially the same, both being very frequently associated, both giving rise to very much the same symptoms, prognosis and treatment, and especially since both involve practically the same part of the radius, and are due to the same cause. According to these statistics fractures of the head and neck of the radius are more frequent than fractures of the patella. In some experimental work performed by the author, six fractures were produced with comparative ease, each one corresponding to the fracture most frequently reported as occurring during life. The only failure that occurred was produced by using excessive force, and in this case Colles' fracture resulted. S.

Pyloroplasty with the McGraw Ligature.—Carstens (*Lancet Clinic*, March 3rd, 1906) reports two cases of dilatation of the stomach due to pyloric stenosis, which were successfully treated by this method. The author describes the technique as follows:—"With a round needle threaded with fine silk, I sewed the duodenum to the stomach from the pylorus downwards for two and a half inches. A curved, Hagedorn's needle threaded with McGraw's (elastic) ligature I now insert into the stomach about two and a half inches from the pylorus, and then down the duodenum for two and a half inches, bringing it out, also about one-third inch from the row of sutures. The ligature was pulled through and made fast in the usual way. I now continue the row of sutures at the end and the other side, and the operation is finished." The patient is given full diet about a fortnight after the operation. In both cases the gastric symptoms were relieved and the patient regained health. S.

Diagnosis of Tuberculosis of the Iris.—Gouriein, Geneva (Soc. Franc. d'Ophthal., Mai, 1905) recommends a method to differentiate tuberculosis of the iris from other nodular diseases of that part. He makes a puncture of the anterior chamber of the diseased eye, and having drawn off the aqueous humour he injects it into the eye or under the skin of a rabbit or guinea pig. Whether he gets a positive or negative result he considers the results are equally useful as an aid to differential diagnosis. He records four cases. Two gave positive results, in which other symptoms developed, one of the cases dying of tubercular meningitis. One with a negative result was put on antisyphilitic treatment with a satisfactory result. M.

Full Correction of Myopia.—Bourgeois, Reims (Soc. Franc. d'Ophthal., Mai, 1905), having studied recent literature gives his conclusions as follows: Most oculists are of the opinion that excessive convergence for near work is the principal cause of the origin and increase of myopia. Full correction has a beneficial effect on myopia. There is a doubt as to the advisability of correcting fully the cases known as malignant myopia. In young people with myopia up to 6D full correction should be ordered and will be well borne. In children with myopia amounting to a fraction of

1D. glasses should be ordered, as it is probable that the myopia is arrested thereby. In myopes of high degrees (over 6D) final full correction has to be reached by easy stages commencing with 7 or 8D, which will be generally acceptable to young adults. In cases over 12D no definite rules can be laid down. In all cases astigmatism should be accurately corrected. Where insufficiency of the internal recti exists the lenses, which should be large, round and perisopic, must be appropriately decentred. The author urges the importance of a correct reading distance (30 or 40 cm.) being observed in the cases of school children, even if it necessitates the use of a head-holder. In progressive myopia the general health of children must be carefully attended to. Javal, in discussing Bourgeois's paper was in favour of all school children being carefully tested as to vision, and of the introduction of vertical writing desks into schools. M.

Collargol in Ophthalmia Neonatorum.—Demits, Anvers (Soc. Franc. d'Ophthal. Mai, 1905) pins his faith to this salt after twelve months trial in these cases, just as others have pinned theirs to protargol and argyrol. He says that it can hardly be questioned that the use of nitrate of silver during the first week of ophthalmia neonatorum may have an injurious effect upon the nutrition of the cornea already endangered by chemosis, and further, it must be applied by skilled hands for a lengthened period. This is not always possible, and it is dangerous to entrust its application to lay hands. Collargol Demits found of equal therapeutic value with the nitrate, and free from the above disadvantages. In a discussion Armagnac, Lagrange and Wickerkiewicz maintained that nitrate of silver still held its reputation in the treatment of this disease in spite of the keen rivalry of the newer organic silver salts. M.

The Surgery of the Thyroid Gland.—Under the head of surgical diseases of the thyroid gland Max Ballin (*New York Med. Jour.*, Feb. 10th, 1906), mentions first injuries and malformations of the gland, then goes on to discuss inflammation occurring in an otherwise healthy gland—i.e., Thyroiditis, and the results of the same process when it occurs in a previously enlarged gland—i.e., Strumitis. The former nearly always subsides, but abscesses may form which should be at once opened. The varieties of goitre and their appropriate treatment are then fully dealt with. The author finally goes on to the subject of exophthalmic goitre. This affection is characterised pathologically by, (1) a thick fibrous capsule, which is not separated as easily as is commonly done from an ordinary goitre; (2) by an increase in the size and number of the blood vessels; (3) a very broad isthmus; (4) the epithelium of the follicles is in a state of proliferation and degeneration. The medical treatment of this disease is not satisfactory. Are surgical measures justified? The author believes they are; he has operated on six cases, removing the greater portion of the gland; three are cured, two are much improved, and one is slightly improved. Recent statistics from 291 cases of this disease operated upon show 165 cures, 77 improved, 12 not improved, and 37 died. Thyroidectomy seems to give better results than either ligature of the thyroid arteries, or excision of the sympathetic nerves. G.

Prostatic Albuminuria as a Cause of Error in Diagnosis.—E. G. Ballenger states in the *New York Med. Journ.*, Jan. 24th, 1906, that albumin in the urine does not always indicate a lesion of the kidney; the secretion from hyperæmic or chronically inflamed prostate glands are a not infrequent source of error in many of the cases of apparently harmless albuminuria. The secretion from a diseased prostate contains a proteid material giving the tests for albumin; this secretion frequently passes back into the bladder and may mix with the urine, leaving it quite clear; as much care should be taken to avoid this secretion as is taken to avoid uterine or vaginal discharge. The author emphasises the following points: (1) the secretion from

an inflamed or hyperæmic prostate is albuminous while that from the normal gland is not, or is present in such small quantities that, unless the seminal vesicles are massaged, the urine passed will not give the tests for albumin; (2) this is apparently a constant symptom of chronic prostatitis and may be depended upon in the diagnosis; (3) prostatic albuminuria seems to be an appropriate name for this condition; (4) in making insurance examinations as well as in the diagnosis of obscure forms of albuminuria, this possibility should be eliminated with the other sources of contamination, before reaching a positive conclusion as to the significance of albumin; (5) the periodic increase in the prostatic discharge, along with the striking similarity between the symptoms of intermittent, postural, orthostatic, and cyclic albuminuria, and prostaticorrhœa makes the possibility of mistakes in the diagnosis extremely likely, when this fluid flows back into the bladder and does not appear at the meatus; (6) this regular increase of this secretion every ten to thirty days, and the analogy between the uterus and the prostate, suggest a relation between the causes of this condition and menstruation. G.

Gastric Surgery.—In a lecture on this subject Mr. H. Paterson (*Lancet*, Feb. 24th, 1906), refers in detail to the operation of gastro-jejunosotomy—more particularly to its immediate and late results; he believes that in most cases "the vicious circle" occurs as a result of faulty technique. The author has been able to follow the histories of 116 cases in which gastro-enterostomy had been performed for non-malignant disease of the stomach, at periods varying from three to twenty years previous to the time of the inquiry. From these cases he draws the following conclusions: (1) That the use of mechanical appliances is attended with uncertain results; (2) that a small opening between stomach and intestine is apt to prove unsatisfactory; (3) that if the mucous membrane of the stomach and the jejunum are not brought into apposition, undue contraction or even complete closure of the opening may result; (4) that about 85 per cent. of the patients suffering from simple pyloric stenosis or gastric ulcer are completely relieved, while in about 7 per cent. of the remaining cases relief is almost complete. Eliminating cases in which a mechanical appliance had been used, or a small opening made, the proportion of cases subsequently relieved is about 92 per cent.; (5) that the risk of subsequent perforation of a peptic jejunal ulcer is under 2 per cent.; (6) that as patients have regained their normal weight, and have lived for years in perfect health, there is no reason to suppose that the operation of gastro-jejunosotomy tends to shorten life. G.

Glaucomatous Cloudiness of the Cornea.—Silex, Berlin (*Arch. of Ophthal.*, July, 1905) believes that in acute glaucoma the cloudiness of the cornea does not depend on an œdema, as has hitherto been supposed to be the case, but upon a stretching of the cornea whereby doubly refracting elements are induced to appear which cause a multiple reflection of light. This theory is based on experimental, clinical observation and pathological anatomy, and a cloudiness of the cornea is produced by injection of fluid into the vitreous which is similar in appearance to that of acute glaucoma. M.

NOTE.—A summary will appear each week in the following sequence:—

- (1) "Recent Medical Literature."
- (2) "Recent Surgical Literature."
- (3) "Recent Gynecological and Obstetrical Literature."
- (4) "The Recent Literature of Physiology, and Pathology."

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

MR. MACLAHLAN.—Tynemouth had the highest aggregate mortality last week of all the large towns with 25.0 per 1,000, Dublin and Belfast came next with 24, Liverpool following with 21, and Glasgow with 20.

BIRTH-RATE AT BRIGHTON.

In his annual report for the year 1905, Dr. Arthur Newholme says the birth-rate has steadily declined for many years. In 1881 it was 30.6 per 1,000, in 1891 it was 28.2, in 1894 it had fallen to 23.5. Stated more accurately, after corrections have been made for the varying proportion of married women and of women at child-bearing ages, the legitimate birth-rate declined from 29.05 in 1881 to 23.34 per 1,000 in 1901, the illegitimate birth-rate from 1.72 to 1.30 per 100, and the total birth-rate from 30.77 to 24.63, which is equivalent to a reduction of 20 per cent. The death-rate works out at 13.6 per 1,000, considerably lower than the death rates of 15.7 and 15.6 in the 76 great towns and in London respectively. A table is given showing that since the year 1861 the death-rate of Brighton has been steadily decreasing.

L. O. B. is thanked, but his communication is hardly suitable for our columns.

POST-CARD.—Our correspondent does not enclose his card or give his name. This is a necessary rule, to which we strictly adhere, as establishing the *bona-fides* of the writer, and we cannot entertain the writer's suggestion in the non-fulfilment of this condition.

MODERN THERAPY.

NOSTRUM AND CO.'S NEW PREPARATIONS.

The following skit anent our attacks on patent medicines and quackery has been sent us by a correspondent:—" 'Humbugaline' and codologine. 'Humbugaline' is angeliatic and haemostatic, suitable for small operations, viz., removal of corns, toe-nails, chilblains, and superfluous hair. Mode of use:—One quarter grain to be dissolved in a bucketful of hot water and used hypodermatically every half-minute. 'Humbugaline' is less toxic than 'codologine' and other vaunted local anaesthetics, but, perhaps, not quite so effective in other particulars. Used with most gratifying results in cases of ingrowing toe-nail. Samples and literature on request. Please specify Nostrum and Co."—A. D.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, APRIL 4th.

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. A. Routh, Dr. Boxall, Dr. Blacker, and Mr. J. Bland-Sutton. Short communication:—Dr. E. J. Maclean: Case of Ectopic Gestation in which the Fetus was removed Six and a Half Months after Spurious Labour at Term. Demonstration:—Dr. A. W. Addison: Chronic Infective Metritis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (23 Chancery Street, W.C.).—4 p.m. Mr. C. Ryall: Clinique. (Surgical.) 5.15 p.m. Lecture:—Dr. E. F. Buzzard: Some Acute Infective Disorders of the Nervous System.

THURSDAY, APRIL 5th.

ROYAL COLLEGE OF PHYSICIANS OF LONDON (Pall Mall East).—5 p.m. Oliver Sharpey Lecture:—Dr. E. I. Spriggs: The Bearing of Metabolism Experiments upon the Treatment of Some Diseases.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (23 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Lecture:—Mr. E. Jones (Liverpool): Internal Derangements of the Knee.

FRIDAY, APRIL 6th.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith, W.).—8 p.m. Clinical Meeting.

LARYNGOLOGICAL SOCIETY OF LONDON (20 Hanover Square, W.).—5 p.m. Exhibition of Cases, Drawings, and Specimens.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (23 Chancery Street, W.C.).—4 p.m. Mr. N. MacLehose: Clinique. (Eyes.)

MONDAY, APRIL 9th.

BRITISH GYNAECOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Exhibition of Specimens: Dr. A. E. Giles, Dr. Frederick Edge, Mr. F. Bowman Jessett, and Dr. Macnaughton-Jones.

Vacancies.

Friendly Societies Medical Aid Association, Kidderminster.—Assistant. Salary £150 per annum. Applications to Dr. Martin, 4 Lion Street, Kidderminster.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary £150 per annum, with apartments. Applications to the Hon. Secretary, Mr. G. A. Lightfoot, 23 Oastie Street, Carlisle.

Egyptian Government.—Kaar-El-Ainy Hospital.—Resident Surgical Officer. Salary £250 a year, with quarters, servants, washing, coal and light. Applications to the Director-General, Public Health Department, Cairo.

Borough of Reigate.—Reigate Rural District Council.—Medical Officer of Health. Salary £500 per annum. Applications to the Town Clerk Municipal Buildings, Reigate.

Gartloch Asylum, Gartloch.—Assistant Medical Officer. Salary £155 with board and lodging. Applications to Medical Superintendent.

Royal Hospital for Diseases of the Chest, City Road, E.C.—Resident Medical Officer. Salary £120 per annum, with furnished apartments, board, and washing. Applications to the Secretary.

Kingseat Asylum.—Assistant Medical Officer. Salary £110 per annum, with board, &c. Applications to C. B. Williams, Clerk, City District Lunacy Board Chambers, 20 Union Terrace, Aberdeen.

Somerset and Bath Asylum, Cotford, Taunton.—Assistant Medical Officer. Salary £140 per annum, with furnished apartments, board, fuel, lighting, washing, and attendance. Applications to the Medical Superintendent.

Royal Halifax Infirmary.—Second House Surgeon. Salary £100 per annum, with residence, board, and washing. Applications to Oates Webster, Secretary, Royal Halifax Infirmary.

Nottingham General Hospital.—Assistant House Physician. Salary £100 per annum, with board, lodging, and washing. Applications to the Secretary.

Cork Branch of the Irish Drapers' Association.—Medical Officer. Emolument, duties, &c., on application to the Hon. Sec. (see advt.).

Appointments.

BUCKLEY, J. C., M.D., Ch.B., Vict., Honorary Assistant Physician to the General Hospital, Nottingham.

CADDICK, C. J., M.B., F.R.C.S., Edin., D.P.H. Camb., Surgeon to the Out-patient Department at the Walsall and District Hospital.

DIXON, W. E., M.B., B.S. Lond., to the Chair of Materia Medica and Pharmacology at King's College Hospital.

DUBOIS, D. J., L.R.C.P., and S. Edin., L.F.P.S. Glasg., Medical Officer to the Cottage Homes, Hornchurch, of the parish of St. Leonard, Shoreditch, London.

HEWITSON, W. A., M.B., Ch.S., L.R.C.P. Edin., Certifying Surgeon under the Factory and Workshop Act for the Haswell District of the county of Durham.

MILNE, L. J., M.D. Aberd., Certifying Surgeon under the Factory and Workshop Act for the Mirfield District of the county of York.

PHILLIPS, JOHN, M.D. Cantab., F.R.C.P. Lond., to the Chair of Obstetric Medicine and Diseases of Women and Children at King's Coll. ge.

POLLOCK, A. K., HALLIDAY, M.B., Ch.S., L.R.C.P. Lond., Medical Officer to the East Indian Railway, India.

SINGER, CHARLES, M.B., B.Ch. Oxon., Resident Medical Officer in Charge of the Government General Hospital, Penang.

Births.

CARRUTHERS.—On March 29th, at 44 Central Hill, Norwood, the wife of S. W. Carruthers, M.D., of a daughter.

LOW.—On April 1st, at 146 Harley Street, the wife of Vincent Warren Low, F.R.C.S., prematurely of a son (stillborn).

NANKIVELL.—On March 29th, at "Woodstock," West Cliff Road, Bournemouth, the wife of Bertram Wright Nankivell, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

PENNINGTON.—On March 25th, at Sandown, Isle of Wight, the wife of Drury Pennington, M.B., B.C. Cantab., of a daughter.

Marriages.

ALEXANDER—GRIMSHAW.—On March 26th, at Caledon Church, Oana Alexander, Esq., only son of Colonel the Hon. Charles Alexander, of Caledon, to Gladys Constance, younger daughter of the late Thomas W. Grimshaw, O.B., M.D., late Registrar-General for Ireland, and Mrs. Grimshaw, Annaghroo House, Caledon, Tyrone.

BRANWELL—BERRY.—On March 31st, at St. Peter's Church, Ealing, Charles Branwell, M.R.C.S. Eng., L.R.C.P. Lond., only son of Charles Branwell, of Penzance, to Eleanor, only daughter of the late John Berry, of K nyon, Ashburton, Devon, and Mrs. Dobell, of Bishopsley Avenue, Ealing.

STUART—LUMSDEN.—On March 28th, at St. Mary's Chapel, East Church, Aberdeen, William Lumsden Stuart, M.D., B.A. Lond., of Oakdene, Camberley, Surrey, to Jean Abernethy, eldest daughter of John Lumsden, Esq., J.P.

Deaths.

ARCHER.—On March 30th, at The Rowells, Manor Road, Sidcup, Ross, widow of the late Edmund Archer, M.D., M.R.C.P., F.R.C.S., of King's Lynn, Norfolk, in her 74th year.

BEALE.—On March 28th, at his residence, Bentinck Street, Manchester Square, London, N., Lionel S. Beale, M.B., F.R.C.P. Lond., F.R.S., Consulting Physician to King's College Hospital, Emeritus Professor of the Principles and Practice of Medicine in King's College, London.

BUCHANAN.—On March 22nd, at Sowerby, Thirsk, John Hamilton Buchanan, M.D., J.P., in his 74th year.

DOLMAN.—On March 28th, at Caerphilly, Charles Dolman, F.R.C.S., fourth son of Frederick Dolman, Woodland Road, Clifton, Bristol, aged 44.

GIBBES.—On April 1st, at Oxford, Catherine Gibbes, widow of Francis Richard Gibbes, M.R.C.S., late of Anerley and St. Leonard's-Sea.

HARFORD.—On March 30th, at Christchurch, Henry William Harford, L.R.C.P. and L.R.C.S., aged 52, youngest son of the late Captain Augustus Harford, 59th Regiment, of Rose Court, Queen's co., Ireland.

HILL.—On March 27th, at Thornton House, West Horsham, William Byron Hill, M.R.C.S., aged 81.

WALKER.—On March 28th, at his residence, Atydos, Longfellow Road, Worthing, Charles Rotherham Walker, M.D. (late of Gainsborough House, Leytonstone), aged 48.

WRIGHT.—On March 29th, at Southsea, Sarah, widow of George Wright M.R.C.S., L.S.A., some time of Fovant, Wilts.

NOTES AND COMMENTS.

Insurance without Medical Examination.

A correspondent writes us in reference to our remarks upon the scheme of life insurance without medical examination adopted by the "Sun" Office. He uses language a little stronger, perhaps, than that warranted by the facts of the case. At the same time we cannot help agreeing with him so far as the illusory nature of the central proposal is concerned. In the vast majority of cases the questions are so framed that applicants are ultimately bound to undergo the ordeal of a medical examination. Those admitted without such an examination we regard as representing so many guineas of which the medical profession has been unfairly deprived. At the same time we believe we are correct in stating that the company protects itself by keeping out of benefit for several years those who are admitted on the non-medical examination scheme. While the "Sun" persists in methods that we believe are unjust to the medical profession and not absolutely and positively candid to the public, so long shall we make it our duty to draw notice to the matter from time to time.

A Prescriptive Right to Pollute a Creek.

The judgment delivered by Lord Justice Vaughan Williams, and concurred in by Lords Justice Stirling and Moulton, affirms a conclusion that will be welcome to all sanitary reformers. It is true that they arrive at their journey's end by circuitous routes, but could lawyers do otherwise in dealing with ancient vested rights and privileges? Since time immemorial Warblington has assumed the right to pour its sewage into the neighbouring creek. That right the Law Lords confirm, and say in so many words that it could do that so long as it causes no injury to anyone. If the plaintiff or any other person, however, could show injury resulting therefrom, it was quite competent for such a person to sue for damages. This is a modern version of the classic judgment delivered against Shylock. You may pollute your neighbouring stream, my good Council, but all the same you will be liable if you injure other persons by its poisoned waters. The far-reaching nature of this legal decision it is hardly possible to estimate. It will greatly strengthen the hands of all who suffer from sewage polluted waters. Will it help to restore prosperity to the diminishing oyster trade

Oysters and Sewage.

At the Appeal Court last week a great victory was scored in the conflict between public health and vested interests. The case arose out of the tragic banquet held at Winchester in November, 1902, when some of the guests contracted typhoid fever from

eating oysters supplied by a Mr. Foster from the Emsworth beds. After this episode the owner of the incriminated beds naturally found his oyster trade ruined. He then brought an action to restrain the Urban District of Warblington from continuing to discharge sewage in the neighbourhood of his oyster beds and at the same time he claimed damages. Mr. Justice Walton found he was not entitled to an injunction, but was entitled to damages. From that judgment the defendants appealed, and after long and costly litigation the solemn verdict of the Lords of Appeal has been delivered. Henceforth, according to this decision, a sanitary authority may poison adjoining waters at its own free will, but it may not poison oysters, and if it can be shown to have caused indirect injury in that, or any other way, it must be held responsible.

Methylene Blue in a Evidence.

The curious property possessed by methylene blue of colouring the urinary secretions of a cerulean hue has placed a practical joker—for such he presumably must be—in a somewhat serious position. At a London police court last week a gentleman with an Army title was charged with administering a noxious drug with intent to annoy. Professing to have a remedy for indigestion in a certain tabloid he persuaded two barmaids to swallow a sample of his medicaments. The result was horribly alarming to the women, and shortly afterwards the "Major" found himself figuring in the dock of a police court. Counsel for the defendant alluded to the remarkable property of methylene blue, and stated that the drug was given not for the purpose of doing harm, but merely as a stupid joke. Even if that explanation be accepted we hardly wonder that the magistrate adjourned the summons while he communicated with the Public Prosecutor. The practical joker must take care not to sail too near the wind or he may find the tables turned upon himself in an unexpected way.

The Crusade Against Consumption.

THE campaign against consumption is being carried on in a fitful way hardly worthy of its early promise. At the recent annual meeting of the National Association for the prevention of that malady the great central feature was the complaint about the smallness of support accorded to the movement. Yet a vast deal has been done and is being at the present moment accomplished by way of checking the ravages of tuberculosis. But when all is said and done it is to official rather than to charitable effort that we must look for the ultimate extinction of the disease. Public health measures go to the root of things, while voluntary charitable missions for the most part simply deal with the accom-

plished evil. For all that, it is true that the National Association has undertaken a supremely important task in the attempt to educate public opinion upon the subject. Sooner or later a fully-informed nation will insist on scientific and universal methods of prevention.

LEADING ARTICLE.

ARMY SURGEONS AND PROFESSIONAL SECRECY.

Two cases involving professional secrecy occurred last week. In one a private medical practitioner was informed by a judge that he was compelled to disclose under oath facts that had come to his knowledge professionally. Under such circumstances, and if the evidence be required in order to prevent a miscarriage of justice, few members of our profession would adopt the extreme view that information acquired under the seal of professional secrecy should not be divulged in a court of law. Should the police apply to a medical man for such information, they are grossly exceeding their powers, and any practitioner foolish enough to play into their hands in that way is breaking one of the most ancient and the strongest traditions of his profession. Then, clearly, there is no obligation to preserve inviolate professional confidences with regard to the patient if the latter consent to their being divulged. The ethical offence consists in a medical man betraying confidences that have come to his knowledge by reason of his relationship with another person in his capacity of medical attendant, in the absence of any direct authorisation by the patient to impart such information. The point, simple and obvious as it may seem, is apt to escape full recognition. It comes strongly into relief as regards the relation of the Army medical officer to those under his charge. The "ragging case" in the Scots Guards, inquired into at Aldershot last week by Court-Martial, raises various points of importance as regards the Army Medical Service. The victim of the horse-play of his brother subalterns was charged at a mock inquiry with being "in an absolutely filthy condition," with not having cleaned his teeth for a month, and with having a loathsome skin disease, to wit—scabies. As the matter is now *sub judice* with the Army Council, under the chairmanship of Mr. Haldane, we cannot discuss the legal and social aspects of the affair. It is a matter for the nation, through its representative government, to determine whether paid public servants are to establish a virtual class monopoly and a happy exclusive hunting ground out of the higher grades of military service. We may ask, however, with perfect propriety, by what authority, official or otherwise, Surgeon-Major Whiston, medical officer in charge of the Guards at Aldershot, reported to his commanding officer that he found one of the subalterns in a very dirty condition—in other words, that he had scabies? Owing to some incomprehensible relic of the days of class privilege in Army adminis-

tration, the medical officers of the Household Troops are not selected from the Royal Army Medical Corps. Surgeon-General Whiston was thus appointed, and it is significant that his evidence as to the condition of Lieutenant Clark Kennedy, the subaltern implicated, was traversed by a Captain, a Lieutenant, and a private of the R.A.M.C. The question that will probably suggest itself to the medical man hearing of these proceedings is whether Major-General Whiston was justified under any circumstances in disclosing the fact, or what he considered to be the fact, that a patient under his care had contracted scabies. As all medical men know, scabies may attack the cleanly as well as the uncleanly, and, moreover, when masked by secondary signs and symptoms, its diagnosis may present at times well-nigh insuperable difficulties. By what code of Army discipline can a medical officer be called upon to disclose such purely professional and delicate information. The crux of the matter, we take it, is the consent of the patient. If information be requisite as to fitness for service, then it may be assumed that the medical officer reports with consent of the individual soldier. But how about scabies, which does not disable, and if scabies is to be reported why not gonorrhœa and syphilis and other conditions due to recklessness and immorality? It is not easy to see how an Army medical officer is to claim immunity from the sacredness of professional confidence any more than his civilian brethren. Were a medical man in general practice to betray a professional confidence he would be forthwith scouted by society and would render himself liable to actions for damages. We fail to see how under any code, official or professional, the Army surgeon can contract himself out of the observance of the conditions of secrecy laid down in the Hippocratic Oath, which have been hitherto the sheet anchor of professional honour and without which it would be difficult, if not impossible, to maintain any permanently staunch relations between medical men and the community at large.

NOTES ON CURRENT TOPICS.

The Normyl Treatment Association.

WHEN, we wonder, will good people and philanthropic people consent to take medical advice on medical questions as they take legal advice on legal questions. More harm, says the old saw, is done by want of thought than by want of heart, and it is pitiable to see benevolence plunging in morasses where it would never have been led under experienced guidance. It appears that one of that most unsatisfactory class of "treatments," namely, a chronic alcoholism and drug habit treatment, has been brought over to England, and under the name of the "Normyl Treatment Association," a society has been formed to apply it at a reduced price! Among the members of this association are many able and well-disposed persons who pledge themselves to make no profit

out of the practice of this treatment, and whose only desire is to reclaim the drunkard. In the light of past experience is it, we wonder, too late to appeal to these people to place themselves in the hands of a Committee of disinterested medical men before recommending a treatment, invented by a "Canadian chemist," of whose operations they can have little scientific knowledge? Mr. Owen Seaman is the treasurer of the Association, and we would entreat him not to lend the influence of his great name to this scheme without authoritative medical advice. Medical men could no more write the inimitable parodies of Mr. Seaman without his skill and erudition than can the distinguished editor of *Punch* judge of a technical professional problem without the experience and training of a medical man.

The Fight against Consumption.

We have received from the Dublin Branch of the National Association for the Prevention of Tuberculosis copies of a poster published by them, and posted in the national schools throughout the country by the authority of the Commissioners of National Education. The death-rate from tubercular diseases in Ireland shows practically no sign of abatement, and there is no doubt that little can be hoped for until the public mind is thoroughly alive to the importance of using every effort to prevent the spread of the disease. In attempting to give plain and simple instruction to the young, the Dublin branch is doubtless proceeding on proper lines. The poster we refer to, which is based on handbills drawn up by Dr. Birmingham, of Westport, is well calculated to fulfil its purpose, since it is couched in language everyone can understand. It is possible that a few of the maxims may be regarded as counsels of perfection, such as the advice "to grind your own corn," and "always to boil the milk before using it." Nevertheless, it would be hypercritical to find fault on such trivial grounds.

The International Congress of Medicine.

THE Seventh Bulletin of the International Congress of Medicine shows that the Lisbon Committee is working hard to make the Congress a success. The Bulletin contains the programme of sittings and discussions, and of fêtes, in addition to much useful information as to lodgings and routes. Among the fêtes, of which the Committee are unable as yet to give a complete list, are a garden-party given by the King and Queen and a dinner to the chief guests, a reception by the President of the Congress and a ball by the City of Lisbon. The list of subjects and papers for discussion promises matter of great interest, and the authors include men of eminence from every country in Europe as well as from beyond the seas. Thus, to take a single example from the section of pathology, we find that the reporters on the question of the parasitic origin of tumours are Dr. Bashford, of London, and Dr. Doyen, of Paris, while contributions on other points in regard to malignant disease are promised from Professor

von Housemann, of Grunewald; Dr. Neves, of Lisbon; Dr. Foulerton, of London; Professor Borst, of Göttingen; and Dr. Gaylord, of Buffalo. The programme is accompanied by very useful plans of the school of medicine, where the Congress is to sit. The railway and steamship fares are extremely moderate, and we are sure those of our readers who can spare themselves a week's holiday cannot do better than go to Lisbon. The Congress meets on the 19th instant.

Dr. Hutchison on Food.

IN selecting "Food and Diet" for his lecture to the members of the National Health Society, Dr. Hutchison found a subject on which it is of great importance that the public should be instructed. At no time has more general interest been taken in such matters, and the many fads and "isms" at present in vogue are evidences rather of this ill-informed interest than of any particular tendency towards foolishness. It is well, therefore, that as far as they can the public should learn the principles underlying the choice of human diet. Two points are essential in deciding on any diet—that the requisite food-stuffs be supplied in proper quantities, and that they be supplied in a form suited to our digestive organs. This latter demand does not at all mean that the most easily assimilable food is the most wholesome. Our digestive organs to remain in health must perform their normal functions and must therefore be supplied with proper material for the exercise of those functions. On the other hand, the "wholemeal bread" craze, and other similar follies depend on views of the other extreme, which assume that waste material must be present in large quantity in order to call forth gastric and intestinal activity. While not prepared to adopt an exclusively vegetarian diet, Dr. Hutchison is quite right in saying that people as a rule eat too much animal food. In this he is probably thinking particularly of the English middle classes, for the remark does not hold with nearly the same force in other parts of the Kingdom than England, and in many parts of the Continent it would be quite untrue. The virtue in matters of diet, as in many other spheres, is temperance—the mean between too much and too little.

Juvenile Smoking.

No one, we presume, would advocate the use of tobacco by unbearded urchins. Smoking is an artificial habit and not an invigorating one, and as such it is best left alone, at any rate till man's estate is reached. But at the same time a good deal of exaggeration is employed by many people in dealing with the subject, and if we were to believe some of them, legislation to abolish the use of the fag-end by newspaper boys would cure half the ills that national physique is heir to. Dr. Macnamara is trying to get a Bill through Parliament to prevent young people being served with tobacco, but it is hardly likely to get Government support this session. Knowing that boys

are imitative animals, and that while their elders smoke they will do likewise when they get a chance, it is doubtful whether such a restriction would have much effect on the total quantity of smoking; it would be perhaps more likely to lead to the surreptitious abstraction of the paternal tobacco, and thus turn a stupid habit into a moral crime.

Lincoln Typhoid Epidemic.

THE official account of the Lincoln typhoid epidemic has just been published in the form of a special report by Dr. Reece, one of the Local Government Board inspectors. The chief value of this report is that it supplies overwhelming evidence in favour of water-infection as the means by which the outbreak was caused, and this epidemic can now take its place alongside those of Worthing and Maidstone as a typical example of its class. The characteristics of a water-borne epidemic are that after a few cases of enteric fever or diarrhoea have been occurring for a short time, a sudden rise takes place in the number of notifications of the former over the area supplied by the waterworks. This condition, as in the cases of the other two towns mentioned, was fulfilled at Lincoln, but owing to the prompt and energetic measures taken no large secondary wave took place. A feature of great interest is that a bacillus was recovered from the waterworks which was in all probability—at least, in the opinion of Dr. Klein—Eberth's bacillus. One of the paradoxes of water-borne outbreaks of typhoid in the past has been that the specific organism of the disease has been conspicuous by its absence, although its congeners of the coli group have been found in more or less abundance; sufficient at any rate to prove sewage-contamination. The experience at Lincoln with regard to the efficacy of anti-typhoid measures brings strongly into prominence the suggestion that has been made that a "typhoid corps" of medical men and trained attendants should be available at a moment's notice to help any town that may be stricken.

Mr. Troutbeck as Pathologist

THE extensive experience that Mr. Troutbeck has gained in connection with pathologists and their functions has evidently led him so far into the subject of pathology, that perhaps it will soon be unnecessary for any medical witnesses to be called at his inquests. We ourselves have always held that the man who was at once a barrister and a doctor made the most suitable coroner, though it must be confessed the majority of appointing authorities seem to think otherwise. But if a coroner as learned in pathology as he is in law is able not only to conduct an inquest but to supply the jury with medical views, without at the same time taking the trouble to qualify as a medical man, a new and economical arrangement of the ratepayers' money may be looked for in the near future. Last week Mr. Troutbeck held an inquest on the body of a student at Westminster Hospital, who, to the grief of all his associates,

had died from septicæmia contracted at a *post-mortem*. Dr. Burnsteyn, assistant pathologist to the hospital, in the course of his evidence, said that it was not the custom of the Westminster men to wear gloves when doing *post-mortems*—a statement that caused Mr. Troutbeck some surprise. Mr. Troutbeck then put a series of questions, tending to show the folly of not wearing gloves, a position which Dr. Burnsteyn met by saying that his predecessor had lost his arm through infection contracted as the result of wearing gloves, and that the practice, in his view, was opposed to common-sense. Mr. Troutbeck, in his summing-up, told the jury what in effect amounted to the opinion that Dr. Burnsteyn did not know what was the best way to manage his own business. Opinions, of course, are divided on the question of wearing gloves at *post-mortems*; perhaps Mr. Troutbeck thinks the best way is to get an assistant to open the body and remove the organs before the pathologist arrives.

Food Adulteration.

THE London County Council have lately been considering the difficult question of how to catch the real culprit in cases of food adulteration. Under the Food and Drugs Acts it is a sufficient defence for a person accused of retailing adulterated articles to prove that he bought them under a warranty and purveyed them in the same condition as he bought them. It now happens that many prosecutions, especially those for the adulteration of milk, fail owing to this defence, and when the authorities seek to get hold of the wholesale vendor it is often found that he cannot be touched as his liability ceases six months after selling his article. Now as many retailers buy their goods under contract, and as many of these contracts run for a long time, the warranty they get is only a general one, and in practice it happens that by the time the blame is shifted on to the wholesale man the six months during which alone he can be prosecuted have expired. Consequently, the game of adulteration and evasion is kept merrily going and the public suffer in health and purse. After long deliberation the Council have decided that the only way to secure an offender is to have the retailer made liable for adulteration and to leave him to take what steps he can against the wholesale dealer; consequently the Council propose to ask Parliament to endorse this decision by amendment of the present Acts. No doubt such a provision will press hardly on certain small retailers, but it seems the only way to put a stop to this nefarious practice.

Shallows in Excelsis.

AT Loughborough last week a painter dressed in clerical attire was charged before the local bench with brawling during a confirmation service conducted by the Bishop of Peterborough. The newspaper report states that this man had previously "greatly shocked" the clergy and churchgoers by issuing circulars stating that he had twice been offered the Bishopric of Peterborough, but

that owing to unforeseen circumstances he had been unable to accept. A year ago he told the churchwardens that the Bishop had been opening his letters, and the churchwardens told him that they would see that it did not happen again. The brawling incident in question consisted in the clerically-attired painter walking up the aisle during the service and shaking his fist before the great ecclesiastical functionary, shouting "Bishop of Peterborough, you are a thief." If the clergy and church-goers were "greatly shocked" by the circulars, one can only conjecture what their feelings must have been at this painful incident. At any rate, the painter was removed, sheep's clothing and all, and hailed before the bench. The report proceeds with unconscious *naivete*—"It was suggested the man was not sane, but the magistrates said the state of his mind was not before them. They fined him 10s." Surely no shallow ever more completely vindicated his right to have a dozen white luses on his coat of arms! If the state of the painter's mind was not before the magistrates, we can only express the fervent hope that the state of the magistrates' mind will soon be before the Lord Chancellor.

OUR WEEKLY PILLORY.

THE journal selected for this week's comment in the matter of the advertisement of undesirable quack medicines is the issue of the *Daily Express* April 9th, 1906. The most objectionable notice of the kind is that of "The New French Remedy—Therapion," which appears in the shape of a twelve line advertisement modestly placed at the end of the last column but one of the journal. The editor may well relegate this nostrum to an obscure corner of his newspaper, for it carries on its face the characteristics of charlatany of a reckless and cruel type. It begins with the statement that this popular remedy was used in Continental hospitals by Ricord, Rostan, Jobert, Velpeau, and others. It is a standing disgrace to our journalistic laws that the names of great medical men should be dragged through the mire in this way by unscrupulous vendors of proprietary medicines. In this case it is obviously false to imply that any of those great men mentioned habitually used "Therapion" or any other secret medicine, or that they, when alive, would have sanctioned the use of their names in connection with any advertised remedy, whether secret or open. To make use of the name of a deceased leader in the medical world by introducing it into an advertisement is one of the cunning devices of the patent medicine proprietor. In our opinion the proceeding should be made a felony, or at any rate an offence for which heavy damages might be recoverable by the medical man himself, if living, or by his heirs and executors, if dead. We can fancy Ricord turning in his grave at the infamy of his name being fathered on a remedy to cure "impurity of blood, blotches, pain and

swelling of joints, derangements of liver and kidneys, pain in back, gout, rheumatism, and sleeplessness," which Therapion claims to do. Surely a man occupying so prominent a journalistic position as that of Editor of the *Express* need not be told that any medicine claiming to do all that is a lie and a sham. Let us point out further that all the persons who buy this worthless stuff on the strength of the advertisement in the *Express* are induced to do so by the paid co-operation of the editor and the publishers of that paper, who, with the rest of the staff and the proprietors, share in the money extracted from the public in this dishonest fashion.

PERSONAL.

THE Armstrong College, at Newcastle-upon-Tyne, is now completed, and will be opened by King Edward before next winter, but the exact date of the ceremony is not yet settled.

TICKETS for the Jubilee Dinner of the Society of Medical Officers of Health can be obtained from Dr. Priestley, 22, Telford Avenue, Streatham Hill, London, S.W.

A NUMBER of former friends and pupils of Sir Henry Littlejohn have decided to present him with a portrait on the occasion of his retirement from the Chair of Forensic Medicine in the University of Edinburgh, Sir William Turner is chairman, and Dr. Francis D. Boyd, Honorary Secretary of the Presentation Committee.

DR. W. T. DEARDEN, is about to resign his position as a Councillor for Crumpsall Ward in the Manchester City Council, having been appointed Medical Officer of the Manchester Port Sanitary Authority.

It is announced that his Excellency Professor von Bergmann, the celebrated German surgeon, is to be invested with an honorary degree of laws by the University of Edinburgh.

PROFESSOR CARL O. JENSEN, of Copenhagen, has been awarded the "Walker Prize for Cancer Research" by the Royal College of Surgeons of England. The Council's reasons for the award are given fully in another column.

MR. REGINALD CHEYNE ELSMLIE, M.S., F.R.C.S., of St. Bartholomew's Hospital, has been awarded the Jacksonian prize by the Royal College of Surgeons, England, for his essay on "The Pathology and Treatment of Deformities of the Long Bones."

THE first appointment to the newly founded "Begley Student Prize" has been made by the Council of the Royal College of Surgeons, England, to Mr. Walter Burford Johnson, of St. Thomas's Hospital, London, in accordance with the report of the Examiners.

MR. JUSTICE GRANTHAM took the chair at the forty-sixth annual dinner of King's College Medical School, held on Monday, the 9th instant, at the Hotel Cecil, London.

DR. LOUIS CHAMPIONIERE, Surgeon to the Hotel Dieu, Paris, has been elected honorary fellow of the English Royal College of Surgeons.

AN Honorary Medal has been bestowed by the same College on Lieut.-Colonel Sir Richard Havelock Charles, in recognition of his gift of anthropological specimens.

A CLINICAL LECTURE

ON

FRACTURES OF THE SHAFT OF THE FEMUR.

By WILLIAM S. HAUGHTON, M.D., B.Ch.
Visiting Surgeon to Stevens' Hospital, Dublin.

GENTLEMEN,—Since the architecture of bone is constructed to resist such strains as compression, bending, and twisting; and since the lamellæ of bone can generally be sub-divided into two systems, one taking up "compression," and the other "tension" strains, it is natural to suppose that these two systems of lamellæ play a very important part in determining the planes of fracture, when a bone is submitted to abnormal strains.

That this is true in the case of double fractures of the femurs under consideration, I think may be proved, by comparison with the normal lamellar structure of the femur as revealed in the Röntgen stereoscope.

Sawn sections of the femur can only show the structure of the bone in a single plane, that of the saw-cut. This shows correctly lamellæ running vertically or transversely; but yields little information as to which lamellæ are rising up to surface of section, and which are passing down from it. In other words, it only shows the structure in the length and breadth of the plane of section. But the structure in the third dimension of space, namely, depth, can at best only be guessed at.

There is no method with which I am familiar which gives a correct reproduction of lamellar bone structure so well as that of Röntgen stereoscopy. By it, at a glance, the whole fabric and mechanical model on which the bone is built may be systematically and accurately studied as a beautiful "transparency," in which length, breadth, and depth stand out in bold relief and accurate perspective. The stereoscopic method which I employ for the study of bone structure is that devised by Mr. McKenzie-Davidson. Working by this method, in conjunction with Professor A. F. Dixon, we were enabled to follow out the details of a spiral arrangement of lamellæ in the shafts of long bones which I believe furnishes a correct explanation of the frequency of "oblique" fractures occurring in such bones, notably the femur, tibia, and humerus. Further, most typical fractures follow a definite rule, in which the plane of fracture coincides with one or other system of lamellæ when these are submitted to abnormal strains.

When the normal femur is viewed in the McKenzie-Davidson stereoscope, an appearance is seen which I have attempted to represent in the accompanying diagram.

Surrounding the medullary canal we have the thick tubular wall of dense, compact bone, which at either end expands and becomes thinned out to a mere shell in the articular regions.

Where this expansion and thinning out occurs, we find the lamellæ (which in the medullary canal region are not prominent, and are confined to its periphery) stretching inwards towards the central axis of the bone, meeting converging lamellæ, with which they are welded at the points of intersection, and passing onwards again towards the surface of the bone. The whole arrangement being on a well-defined mechanical model, whose component system may be readily analysed into "compression" and "tension" systems, admirably adapted at once to take up "compression" on the articular surface, and to resist the "stresses" of muscular "tensions," when the muscles come into action.

On referring to this diagram, in which the femur is represented as seen from the front, we see that the lamellæ in the upper end may be conveniently sub-divided into four systems—two arising from the com-

compact tissue on inner side of bone, and two from that on the outer side.

On the inner side, a system (Nos. 1, 1) of straight lamellæ arises from the compact bone near the lesser trochanter, and under side of neck (opposite to the dotted lines of lower bracket 1), and these pass in radiating form straight to the upper half of head, where they receive the weight of body, acting in "compression" (upper bracket 1 under right-hand arrow).

Just below this straight system, a short curved system of lamellæ (lower bracket 2) arch upwards and outwards (upper bracket 2) to support (also under "compression") as buttress arches, a long curved system, which arises from the compact bone on outer side of shaft, below great trochanter.

This third system of lamellæ (lower bracket 3) arches inwards in a long easy curve through the neck, and emerges on the articular surface of lower half of head (upper bracket 3). The weight of the body applied to the inner end of this long arching system, throws some of its members at least into "tension."

A fourth system of lamellæ passes nearly vertically upwards into the great trochanter and becomes continuous in direction with the pull of the glutei inserted there, when thrown into "tension" (left-hand arrow pointing to figure 4).

When the muscles operating the hip-joint are thrown into action, there is a sort of "shearing stress" established in the upper end of femur, in the inter-trochanteric region, as the result of the combined "compression" of inner side of bone, and "tension" on outer side. Where this stress is greatest, there spiral lamellæ are most evident, and they form a right and left-handed intersecting system.

A closer inspection of the upper end of femur in the stereoscope, from different points of view, suggests that the first three systems mentioned are really members of the spiral systems (seen in shaft of femur) coming up from below, and becoming distributed over articular surface in the manner best suited for mechanical support.

As we pass down the shaft, the compact walls of medullary canal assume a more or less cylindrical form. And applied to the internal surface of the wall of this canal are seen oblique lamellæ passing round the bone in spiral form; generally there are two systems, right-handed and left-handed spirals. This arrangement braces the structure of the bone very firmly together, and confers the maximum rigidity, with the minimum of bony material.

As we approach the lower end of femur, these spiral lamellæ alter their direction, and pass by easy curves, finally almost vertically downwards into both condyles, emerging perpendicularly to articular surface of pressure. In addition there are two systems of straight perpendicular lamellæ, of great strength, passing from the compact bone of supra-condyloid regions above, down into the articular surfaces of the corresponding condyles. These are arranged chiefly in antero-posterior planes. Thus they take "compression" on their ends.

Above and through the condyles we see some transverse lamellæ, passing across at the epiphysary level, which prevent the bone from spreading, when the condyles are under pressure. This system acts as "tie-beams" and represents "tension" lamellæ.

This arrangement is practically constant near the articular surface of all long bones, offering a wide surface of pressure.

Now fractures of the shaft of the femur are usually oblique, often presenting sharp V-shaped extremities. And their obliquity closely corresponds with the direction of these spiral lamellæ. When V-shaped, the angle included by the V is very closely related to the intersecting angle of the right and left-handed spiral lamellæ. Further, some fractures of the shaft, chiefly at upper end, are spiral. All of which facts suggest that the visible plane of fracture is very largely the outward expression of the internal structure of the bone. The line of cleavage representing the path of least resistance under a given combination of abnormal strains.

Illustrations of this fact might be cited in connection with almost every typical fracture, with which we are familiar.

Now let us consider the recent skiagrams of the case under consideration.

I am indebted to my colleague, Dr. Stevenson, for skiagrams of the right and left femora, both of which were fractured. The right at junction of middle and upper thirds, and the left just above lower third. In these the planes of fracture are oblique, and their obliquity closely corresponds with that of the spiral lamellæ seen in the stereoscope. Further, in one of these there is distinct evidence of a spiral fracture passing half-way round shaft.

This patient's case is a remarkable one. The boy, M. H., æt. 6, was admitted to Steevens' Hospital some four months ago, with a history of having been pushed by his brother, while playing in the street, against the wheel of a passing dray. Both legs passed through the spokes of the wheel, and in this position rotated with the wheel, getting crushed against the springs and body of cart.

On admission, he was in a state of considerable shock, and suffering from the following injuries: Simple fracture of right femur, upper third; compound

fracture of left femur, lower third; rupture apparently of all ligaments of left knee, except internal lateral; compound very oblique fracture of left tibia just above middle of bone; compound fracture of left fibula, about two and a half inches above external malleolus; both ends of fibula were protruding and partially denuded of periosteum. This last fracture (fibular) was complicated by a very extensive lacerated skin wound passing obliquely more than half-way round leg above ankle, exposing both bones, and a large extent of lacerated and contused muscles and tendons. The foot hung at right angles with leg, and appeared to be attached merely by a strip of skin and the tendons.

On being called to see the patient, the case appeared to be one for primary amputation. But after a rapid examination, as I found good circulation present in the toes, and the child being young and strong, I decided to give the foot a chance, and rely on a very careful cleansing of the skin, and an aseptic treatment of the compound wounds, which is my usual practice. That the treatment was justified in this case, I think the result proves. Of course, the usual signs of fracture of the shaft of femur were present, *i. e.*, shortening, and swelling of the thighs due to muscular contraction of quadriceps and hamstrings; and both legs lay helpless on the operating table, rolled outwards; crepitus and abnormal mobility at the seats of fracture being only too apparent. In addition, the left knee was a "flail," and the left foot was pendant.

Having decided to spare the foot, there were now two things to be done. (1) To disinfect the skin of legs, and cleanse the compound wounds as thoroughly as possible; and (2) to immobilise the multiple fractures. To carry out all this thoroughly in a serious case, it is very necessary to give an anæsthetic, which I find not only permits better work being done, but also greatly diminishes the shock due to the necessary handling of extensive and painful injuries of bone. Where an adult is concerned, with powerful muscles, this is still more needful.

Accordingly, my colleague, Dr. C. M. Benson, induced ether anæsthesia. Before doing so, full operation preparation of hands, &c., was gone through, including boiled rubber gloves and sterilised overalls, by operator and assistants, as it is very essential to preserve intact the aseptic chain of treatment for success in such cases.

The skin of legs was then thoroughly scrubbed with soap and hot water, followed by ether and alcohol. Then all visible particles of dirt were picked out of all the compound wounds with sterilised forceps. And then the wounds were very thoroughly irrigated from below upwards by rubber tubes, with "normal-saline" at body temperature, till, about three gallons had been flooded through wounds.

It is very important to admit no antiseptic inside wounds, using saline alone. If this point is observed, and absolute fixation obtained by plaster, the majority of compound fracture wounds heal by first intention, or, when contused, by primary granulation.

Drains of silkworm gut were then passed to bottom of each wound, and a few points of suture applied to the wound above ankle.

Next came the fixation of these multiple fractures. Many appliances have been used for fixing fractures of the femur, amongst which I may mention Liston's long splint, Mackintyre's double-inclined plane, and Hodgen's sling splint. In careful hands each of these have yielded excellent functional results. But Hodgen's splint is the only one of these which promises recovery without shortening. All suffer from the necessity of frequent adjustment of bandages, and demand from the surgeon and assistants considerable mechanical skill. Where the dressing of compound fractures is necessary, pain to the patient and great trouble to the surgeon are entailed.

Where plaster of Paris is employed as a primary treatment, all these difficulties disappear; and in a case like the one under consideration, I believe it to be the only form of treatment which could have yielded such a good result.

Accordingly, a pair of plaster of Paris "breeches," like fishing "waders," was applied, having first covered all wounds with sterile dressings, and swathed both legs and abdomen and thorax with a single layer of absorbent wool. Two assistants being posted, one at each foot, making gentle traction, with the feet at right angles to legs; another assistant making counter extension with a long towel under thorax, coming up each side at axillæ.

The child being suspended all the while in an apparatus, devised by my friend, Dr. Robert Halahan, of Buenos Ayres, while house surgeon of Steevens' Hospital, which consists of two iron rods in the form of a V, slung between two tables, and fixed by two cross-pieces of iron one on either table, at any desired angle of abduction, the distance between feet in this case being eighteen inches. Plaster was applied in the form of a broad roller spiral bandage, and extended from both feet nearly up to axillæ. A broad cleft was left for urination and defæcation, and a window cut in the plaster while soft over the principal compound wounds. A cross-piece of wood was attached from one foot to the other, by firmly applied bandages. This afforded further fixation, preventing independent motion of the two legs, and diminishing the tendency to cracking of plaster at the joints. This tendency was further prevented, by the incorporation of long wooden strips in the plaster bandages at each joint level.

The addition of the cross-piece of wood to the plaster "breeches" forms a rigid "triangle," which greatly simplifies the nursing and handling of such cases, especially when turning the patient over for cleaning-up purposes.

The mechanical principle of this plaster "breeches" provides "extension" by the grip which the plaster holds in ankles and feet. "Counter-extension" is maintained by the plaster V pressing on perineum, and its general grip all over pelvis. This "counter-extension" was further reinforced, very efficiently, by tight slings from wooden cross-piece and legs to foot of bed, which was raised some eight inches. The weight of the trunk, head, neck, and upper extremities, in addition to the upper part of thighs, all sliding down an inclined plane towards head of bed. And thus maintaining a continuous pull of counter-extension away from the lower extremities.

The convalescence of this case was uneventful. He slept six hours the first night without any opiate. He never had any pain. His temperature rose to 100° F. the first two nights, and remained normal after. The compound wounds were all healed in a fortnight, with the exception of the contused and lacerated wound above ankle, which was healed in six weeks. And the total number of dressings amounted to five or six. He can now walk, and run about, and bear his full weight on either leg; and has a full range of motion in all the joints. The only resulting deformity is a knob of callus marking each fracture, and a subcutaneous V point of bone on left tibia. All of which results emphasise the value of an aseptic treatment of wounds in compound fractures, combined with the splendid fixation afforded by primary plaster of Paris splints.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of the journal. The lecture in next week's will be by H. D. Rolleston, M.D. Cantab., F.R.C.P. Lond., Physician to St. George's Hospital and Physician to the Victoria Hospital for Children, "On Mitral Stenosis."

News comes to hand that a case of plague has been declared at Port Said.

It has been decided that the administrative duties of Senior Medical Officer of the London Recruiting Area shall in future be performed by the Principal Medical Officer of the London District, who will also be Medical Inspector of Recruits.

ORIGINAL PAPERS.

THE BACTERIOLOGY OF AURAL AND NASAL DISCHARGES IN SCARLET FEVER AND OTHER DISEASES.*

By C. J. LEWIS, D.Sc. (Public Health), M.D., F.R.C.P.,

Lecturer on Public Health, School of Medicine of the Royal Colleges, and Medical College for Women, Edinburgh.

IN the course of a research into the micro-organisms associated with inflammatory diseases of the upper respiratory tract, it appeared that an examination of the discharges from the nasal chambers and ears in scarlet fever and other infective diseases formed an important branch of the subject, and might possibly yield fruitful results. For the provision of material for this investigation I am indebted to the kindness of Dr C. B. Ker, Superintendent of the Edinburgh City Hospital. Also I desire to acknowledge with gratitude the help accorded by Drs. Prichard and Monnington, Resident Physicians to the Hospital, in taking swabs for me from the various cases. The research may be most briefly set forth by first describing the methods employed. (a) These did not differ materially throughout the investigation. Thereafter the results will be stated in regard to individual diseases, and some general conclusions may be formulated from these results.

Methods.—Specimens of the discharges were obtained by means of sterile swabs. The specimens were collected with careful precautions, so as to obviate, as far as possible, contamination by contact of the swabs with anything but the discharge. Particularly was this the case in rhinorrhœa, where hairs and crusts in the vestibule need to be avoided, though it was not always easy to obtain the specimen from the interior of the nasal cavity of young children. On receipt of the swabs at the laboratory, it was sometimes possible to prepare direct films and, on staining these, to determine approximately the various kinds of organisms present. But much more than this was necessary to disclose the particular organisms in each case, and cultivations on artificial media were always made. The swab was rubbed over the surface of blood serum or agar in tube and the medium was incubated at 37° C. The swab itself was then immersed in sterile broth and also incubated at 37° C. Next day the cultures on solid media were examined and the broth plated out. The plating out of the broth was required, as it seldom contained only one variety of organism. The plates were made of serum-agar, of agar, or of jelly, and it may be noted that the serum should not be omitted in a thorough investigation, owing to the frequent presence of the pneumococcus in the discharges. It is difficult to isolate this organism if serum be absent from the media. Consequently, I found the serum-agar plate the most satisfactory medium; it best reveals the pneumococcus and diphtheria bacilli in impure cultures. The serum-agar plate may be made in two ways: either (1) by adding serum, such as hydrocele or ascitic fluid, to the melted agar just before pouring the plate; or (2) by spreading the serum over the surface of the cold agar after it has solidified in the plate. The former is the better method. The impure broth culture which is being plated out may be spread over the surface of the plate with a platinum spreader. This gives only superficial colonies in the plate, and from these pure sub-cultures may easily be obtained. The original broth in which the swab has been immersed for eighteen to twenty-four hours at 37° C. may be used for spreading the plate, but as the growth in this broth culture is frequently too copious, it is well to use instead either (1) a dilution, in sterile broth or water, of this original broth, or (2) a sub-culture of this original broth prepared by

* From the Laboratory of the Royal College of Physicians, Edinburgh. (a) "The Scottish Medical Journal," Nov., 1905.

inoculating a fresh broth tube and incubating it at 37° C. for one hour.

In each case submitted to examination the organisms present were isolated by this method in pure culture, and their characters determined by staining and by subcultures on various media. In many cases the pathogenicity of the organisms thus isolated was tested on animals, such as the rabbit and guinea-pig.

Scarlet Fever—Otitis media suppurativa.—There were forty-six cases of this nature from which swabs were taken. It was quite exceptional to obtain a pure culture, or to find present only one organism to which the condition could conceivably be due. In only three of the cases were the cultures practically pure, and each of these exhibited a different organism. In one case, in which the swab was taken at the very commencement of the discharge (on the first day of discharge and very early after its discovery), the only pyogenic organism present was the pneumococcus. *Sarcina flava* also appeared in the plate, but nothing else, and it may have been a contamination from the air. In the second case the only organism present was a diphtheroid bacillus, which was non-pathogenic to a guinea-pig, but otherwise much resembled true *B. diphtheriæ*. In the third case the streptococcus pyogenes was present with only *sarcina flava* as a companion. Of the other forty-three cases, ten showed two varieties of organism, twenty-four showed three, eight showed four, and one case showed five varieties present. There are four great groups of organisms which far exceed in frequency of incidence all others. These are the pneumococci, the staphylococci, the streptococci, and the diphtheroid bacilli. Every case shows one or more of these four groups. The three former need no exposition; but in regard to the diphtheroid bacilli, it is advisable to explain that included in this term are the true *B. diphtheriæ* (Klebs-Löffler), the pseudo-diphtheria bacillus, and the bacillus of Hofmann. The bacillus of Hofmann does not produce acid in glucose broth, but most of the other members of this group of bacilli have this power. Of the forty-six cases, thirty showed staphylococci, thirty showed diphtheroid bacilli, twenty-nine showed streptococci, and twenty-six showed pneumococci. Other organisms occasionally met with were the bacillus mesentericus, proteus vulgaris, bacillus coli communis, and sarcina. The bacillus of Hofmann was present in twelve cases, and in five of these it was the only bacillus of its group present; in the other seven it was accompanied by diphtheria or pseudo-diphtheria bacilli. Thus there were twenty-five cases showing diphtheroid bacilli, other than *B. Hofmann*, and the great majority of these organisms produced acid when cultivated in glucose broth. In only four of these twenty-five cases were there organisms present which morphologically resembled diphtheria bacilli, but which failed to produce acid in glucose broth cultures. The most common bacilli were those akin to *B. diphtheriæ* (Klebs-Löffler) in morphology and in acid production, but differing from it in pathogenicity to guinea-pigs and in typical reaction to Neisser's staining method. These bacilli, isolated from ten cases, were injected into guinea-pigs, but without any pathogenic effect.

The pathogenicity of the pneumococci was tested in nineteen of the twenty-six cases in which their presence was ascertained. The organisms were virulent in five, or a pathogenicity of 26 per cent. The streptococci, similarly investigated in eighteen cases, proved pathogenic in eight. This gives a pathogenicity of 4 per cent. The staphylococci were tested in sixteen of the thirty cases, and proved pathogenic in four—a pathogenicity of 25 per cent. In analysing the results of the experimental injections of cultures of these organisms, it was noticed that when the swab had been taken near the onset of the discharge the organisms possessed greater virulence. Limiting our consideration only to those cases in which the swabs were obtained within a week of the commencement of discharge, it appeared that the pathogenicity of the pneumococci, staphylococci, and streptococci was respectively 55, 50, and 77 per cent.

That is to say, that during the first week of discharge the pus contains virulent organisms, and in later weeks the organisms are seldom sufficiently virulent to produce illness in the animals tested. Of the seventeen pathogenic cultures referred to above, fifteen were obtained from cases in which the discharge had lasted less than a week, and two from cases in which the discharge had lasted from one to two weeks. In cases of longer duration than a fortnight, none of the organisms tested proved virulent to animals.

Scarlet Fever—Rhinitis.—There were twenty-six cases of this nature from which swabs were taken. In only four of these was the discharge mono-organismal. The organisms present in these four cases were the streptococcus conglomeratus, the streptococcus pyogenes longus, and the staphylococcus pyogenes aureus (twice) respectively. The other twenty-two cases showed various combinations of organisms, there being two varieties present in ten cases, three varieties in ten cases, and four varieties in two cases. The organisms present included many different kinds. The pneumococcus was present in six of the twenty-six cases, staphylococci in seventeen cases, and streptococci in eighteen cases. Diphtheroid bacilli were present in fifteen cases. In seven of these the particular organism proved to be the bacillus of Hofmann, and in seven the pseudo-diphtheria bacillus; while in one case both of these were present. Other organisms occasionally isolated from these cases of scarlet fever rhinitis included the bacillus mesentericus and proteus vulgaris. In two of the cases the pus contained neither streptococci nor staphylococci, but only the pneumococcus and the bacillus of Hofmann in combination.

The pathogenicity of the organisms present in rhinitis resembles fairly closely that of those met with in otitis media. Thus the pneumococci showed virulence in 25 per cent., the streptococci in 44 per cent., and the staphylococci in 33 per cent. of the cases tested. Further, it was in the first week of discharge that most of the pathogenic varieties were met with, and the percentage pathogenicity at this stage amounted to 50, 75, and 60 per cent. for the pneumococci, streptococci, and staphylococci respectively. While the pneumococci and staphylococci were not recovered in a virulent state when the discharge had lasted longer than a week, the streptococci were sometimes virulent at later periods. Pathogenic streptococci were isolated during the second and third weeks of discharge, and in one case even after the discharge had persisted for more than one month. This contrasts somewhat forcibly with the absence of pathogenicity in the specimens from the ear discharges of similar duration.

Whooping-Cough—Rhinitis.—In four cases of whooping-cough there was a discharge from the nasal chambers which was examined bacteriologically. The pus in each case contained staphylococci, and in no case contained streptococci. In two of the cases pure cultures of staphylococci were the only organisms isolated from the pus. In one of these, the staphylococcus pyogenes aureus and in the other the staphylococcus pyogenes citreus was present. Both these staphylococci were non-pathogenic on injection into guinea-pigs. The pneumococcus was found in two cases and a diphtheroid bacillus in one case. This bacillus did not stain by Neisser's method, and was non-pathogenic to a guinea-pig, but produced acid on cultivation in glucose broth. In all four cases of whooping-cough the rhinitis was of short duration. The discharge had lasted in one case less than a week and in the other three cases under a fortnight.

Diphtheria—Otitis media.—Five cases of otitis following diphtheria were examined, and in four of these the discharge had only lasted from three to ten days. In no case was the pus mono-microbic, and usually it contained two or three kinds of organisms. The pneumococcus was present in three cases, staphylococci and streptococci in two each, and diphtheroid bacilli in all cases. These bacilli did not stain by Neisser's method. One case showed the bacillus of Hofmann, and two cases exhibited diphtheroid bacilli

which produced acid in glucose broth. In three cases there was present a bacillus morphologically diphtheroid, but incapable of producing acid in glucose broth. This organism on agar plates grows as a dark smear or dark grey-green colonies, which $\times 105$ show a granular substance with dark nuclei scattered throughout it. The organisms, $\times 800$ in hanging drop, appear as long, non-motile rods, often at an angle with each other. These rods stain irregularly with Lömer's blue stain and appear barred and segmented. They are stained positively by Gram's method, but do not stain by Neisser's method. The bacillus mycoides was present in one case.

Diphtheria—Rhinitis.—Six cases of rhinitis following diphtheria were examined. Staphylococci were present in five, streptococci in three, and the pneumococcus in one case. Bacilli of the diphtheria group were present in all cases. These diphtheroid bacilli included a virulent *B. diphtheriae* (Klebs-Löffler) in one case, while in three cases the bacilli were non-pathogenic and negative to Neisser's stain, but capable of producing acid in glucose broth. The bacillus of Hofmann was present in three cases, and bacillus mesentericus in two cases. No case was mono-organismal, and there were seldom less than three varieties of organisms in the pus.

Measles—Otitis media.—Five cases of otorrhœa complicating measles were examined, four of these within two to five days from the commencement of the discharge. In the fifth case the duration of discharge had been between two and three weeks. This latter case should, perhaps, be excluded, as in reality it was scarlatinal otitis, the measles attack having followed scarlet fever. The streptococcus pyogenes was present along with *sarcina flava*, and the streptococcus was pathogenic to a guinea-pig. The other four cases, all recent in origin, and all in children ranging from two to five years of age, showed no streptococci, but all yielded staphylococci. In one of the cases, which had only lasted two days, the pus contained staphylococcus pyogenes aureus and albus. The former proved fatal to a guinea-pig in three days after the subcutaneous injection of 2 c.c. of broth culture, and was recovered from the pus of an abscess at the site of injection in the flank. It was not recovered from the heart blood, but there was serous effusion in the pleura and peritoneum, and the blood was fluid or semi-fluid. The staphylococcus albus also proved fatal to a guinea-pig, but only after twelve days, and the organism was recovered from the heart blood. In the second case the pus yielded a non-pathogenic staphylococcus pyogenes aureus and the bacillus mycoides. In the third case the pus contained the pneumococcus and the bacillus of Hofmann in addition to the staphylococcus pyogenes aureus. In the fourth case the organisms present were the staphylococcus pyogenes albus and a bacillus, diphtheroid in morphological character but incapable of producing acid in glucose broth.

Measles—Rhinitis.—Five cases of rhinitis following measles were examined bacteriologically. The pus from one of these cases, which had lasted a fortnight, gave a pure culture of the pneumococcus, but the pus in the other four cases was polymicrobial. Of the five cases the pneumococcus was present in four, staphylococci in three, streptococci in two, and the bacillus of Hofmann in two. Diphtheroid bacilli, other than the bacillus of Hofmann, were present in two cases accompanied by that organism, and in one case without it. These bacilli were all negative to reaction with Neisser's stain, but produced acid in glucose broth. The pathogenicity of the organisms present in these cases of measles rhinitis was not tested. The duration of the discharge in the five cases varied from one week to one month.

Otitis media not associated with an Acute Infectious Disease.—Swabs were obtained from three cases of otitis media occurring independently of infectious disease. These were utilised for comparative purposes, and exhibited organisms of similar kinds to those

already noted in cases following infectious diseases. Staphylococci were present in all three cases, streptococci in two, the bacillus mesentericus in two, while proteus vulgaris and a diphtheroid bacillus were found in one case. The pus was derived in one case from an acute suppurative otitis occurring in a child, æt. 3. The organisms present were the staphylococci aureus and albus, the streptococcus pyogenes and the bacillus mesentericus. Notwithstanding the acute nature of the illness, none of these organisms proved pathogenic on injection into guinea-pigs.

Mastoid Abscess.—In six cases of mastoid abscess, pneumococci were present in five, streptococci in five, and staphylococci in three. With the exception of one streptococcus, all these were tested as to virulence in culture, but none were found pathogenic to animals.

Frontal Mucocele.—In one case of suppurating frontal mucocele both staphylococci and streptococci were present. At the time of operation the pus contained streptococcus pyogenes and the staphylococci aureus and citreus. Ten days later a swab from the discharge on the dressing contained the streptococcus pyogenes and the staphylococcus albus. The streptococcus after isolation in pure culture was not pathogenic to a guinea-pig.

General Conclusions.—From the examination of the aural and nasal discharges in these 107 cases of varied origin, the following conclusions appear justifiable:—

1. Purulent discharges of aural and nasal derivation exhibit a variety of bacteria, and do not depend upon a single micro-organism common to all cases.
2. There are four main groups of organisms which exceed all others in frequency of occurrence in such discharges, viz., pneumococci, streptococci, staphylococci, and bacilli of the diphtheria group. These, however, do not comprise all the varieties which the pus may contain.
3. Pure cultures from these discharges are the exception rather than the rule, yet they occasionally occur, and may be met with in about 10 per cent. of the cases.
4. While the discharges are not usually monomicrobial, and do not always contain the same organisms in particular diseases, nevertheless the bacterial contents of such discharges associated with individual diseases present distinctive differences. For example, in this series of cases the aural and nasal discharges in diphtheria always contained bacilli of the diphtheria group, the nasal discharges of whooping-cough always contained staphylococci, and the aural discharges of measles likewise always contained staphylococci. The absence of streptococci in the rhinitis of whooping-cough, and in the otitis of measles, may be accidental, but is certainly suggestive in contrast to their prevalence in the otitis and rhinitis of scarlet fever. In the pus from a mastoid abscess, pneumococci and streptococci are more common than staphylococci.
5. In scarlet fever, aural suppuration is not always due to the same organism. Either the pneumococcus, the streptococcus pyogenes, or a bacillus of the diphtheria group may be responsible, and, having regard to the frequent presence of staphylococci in such pus, there is no reason to doubt that cases occur in which a staphylococcus is similarly responsible, though, as it happened, no case in this series showed a pure culture of a staphylococcus.
6. In scarlet fever, nasal suppuration may be of streptococcal, staphylococcal, or pneumococcal origin. Probably it may sometimes be due to bacilli of the diphtheria group.
7. In scarlet fever the pneumococcus is present in otitis much more frequently than in rhinitis. It occurred in 56.5 per cent. of the former, and only in 23 per cent. of the latter cases.
8. In scarlet fever the organisms present in aural and nasal discharges are less virulent in the later than the earlier stages of the suppuration.
9. In the rhinitis of scarlet fever, streptococci may

retain their pathogenicity even when the discharge has lasted for more than a month.

10. If the infectivity of post-scarlatinal discharges bears any relation to their source and duration, or depends upon the pathogenicity of the organisms present, these observations suggest that otitis and rhinitis are equally dangerous in their early stages, but that the nasal discharge is more likely to contain virulent streptococci in its later stages. Perhaps one may go further and suggest that rhinitis may be the most fruitful source of consecutive and "return" cases. I am not aware whether this indictment of rhinitis coincides with the general experience of hospital physicians, but some confirmation of it is afforded by the opinion expressed by Dr. Pugh in a recent address on the infectivity of scarlet fever.

11. The frequency with which bacilli of the diphtheria group are present in the aural and nasal discharges of scarlet fever is very notable. It suggests that scarlet fever and diphtheria may bear a closer relationship than is commonly assigned to them. The epidemiology of these diseases in particular localities requires, and would probably repay, more thorough comparative study.

THE ALCOHOLIC CRAVING.*

By HARRY CAMPBELL, M.D., F.R.C.P.Lond.,

Physician to the West-End Hospital for Nervous Diseases, President of the Society for the Study of Inebriety.

Mankind all the world over shows a liking for stimulants in one form or another, and sometimes this liking may amount to a veritable craving. This widespread desire for things stimulating must have a physiological basis, and can best be explained by the fact that stimulant substances are normally present in the blood and lymph and exercise a beneficial influence on function. A stimulant may be defined as something which renders pent-up energy available for use, and at the same time tends to evoke a feeling of well-being, exhilaration, or even slight intoxication. Reference was made to chemical stimulants only. There is evidence that the blood normally contains stimulants. Many kinds of food contain them in abundance; but of all foods meat is the most stimulating. In the making of beef-tea the stimulating substances are dissolved out of the meat, while the foodstuffs are for the most part left behind, so that this beverage is essentially a stimulant; and there can be little doubt that the popularity of a meat diet is largely due to its stimulant effects. Bird is somewhat less stimulating than butcher's meat, and fish much less so than either. Some vegetable foods are highly stimulating; a purely vegetable meal may suffice to make children hilarious and excited. It is well known that maize, beans and oats have a stimulant effect on horses, and there can be no doubt that the vegetable-feeding animals select their food as well for its stimulating as for its nutritive properties. Apart from the stimulants, which are normally ingested with the food, it was suggested that the animal organism normally elaborates these substances; and that their essential function is to stimulate the nervous system. By means of them the sensory system of the skin and deeper structures, but especially of the viscera, is played upon, and there ensues a feeling of well-being, ill-being, or apathy, according to the nature of the chemical substances present in the body fluids. These may be divided into (a) the stimulating and tonic, which tend to create a sense of well-being, with its emotional accompaniment of happiness and elation; and (b) those which depress the nervous system, inducing a feeling of ill-being with its emotional accompaniment of gloom, irritability, and the like. They play upon the nerve instrument, and according to the preponderance of the one or the other class there is discord, while if they neutralise one another there is simply apathy or a negative feeling. In their absence there would presumably be merely a feeling of indifference. Many considerations support the view that the organism is capable of generating

stimulants. Such a substance as uric acid, which some have supposed to be a poison pure and simple, produces, when swallowed, a stimulating effect. Again, it sometimes happens that a nerve-storm—such as megrim—is preceded by a period of exceptional well-being and unusual good spirits. It is difficult to explain this preternatural elation—for to such it may amount—except on the assumption that it is produced by some stimulant or stimulants which act like opium or alcohol, and it is on similar lines that we can best explain the occurrence in subjects of general paralysis of the insane of a sense of exuberant well-being. It seems not unlikely that the intoxicated joy of youth and the inspired moments of genius may also be brought about by autogenetic stimulants. *Practical Deductions.*—When there is perfect health the blood is well provided with its proper stimulants and not overcharged with depressants, and there is no craving for extraneous stimulants, such as alcohol or tea; but when it is defective in the one or surcharged with the other then is felt the desire for the glass of wine or the cup of tea. In order to obviate this desire we should seek to keep the body at the highest level of health. When man ceases to rely on his own proper physiological stimulants, and resorts to artificial ones, he is playing with double-edged tools.

TROPICAL ABSCESS OF THE LIVER.

By G. P. NEWBOLT, F.R.C.S.ENG.,

Surgeon to the Royal Southern Hospital, Liverpool.

The author stated that his paper was based on cases seen in the tropical wards of the Royal Southern Hospital, Liverpool. In all his cases there was a history of dysentery. Amœbæ were found in the sloughs from the abscess wall in several instances, but only once in the motions. The tendency was for the abscess to point posteriorly through the chest wall. In two patients the abscess opened into the lung, and the pus was expectorated, but it was necessary to drain the abscess freely by resecting rib; both cases recovered. The material expectorated was brownish in colour and contained broken-down liver cells. One of these patients had three abscesses opened and drained during a period of four years, but made a perfect recovery. In another two abscesses were opened during life, but a third lay between them and was not discovered. Mr. Newbolt laid stress on the importance of exploring with a long needle of large calibre, and also drew attention to the fact that a man with a liver abscess might go about with a normal temperature, without much discomfort, but that the pulse was usually quickened. He considered it most important that the dysentery should be cured before the patient was discharged, as this disease was often made light of at the time and might cause fresh infection. In one case the dysenteric pain was so acute that exploratory laparotomy was performed, nothing abnormal was found in the liver, and the patient was cured by syphoning the large intestine with a solution of nitrate of silver, 20 grs. to the pint. In the cases which recovered the pulse rate declined directly after the abscess was opened; if the pulse-rate kept up it was probable that there were other abscesses present, or the dysentery was very severe. Experiments in the *post-mortem* room showed that the healthy liver would not hold stitches, but after opening the abscess through the abdominal wall in most cases, the liver being inflamed, the stitches held; though

* Opening address to a discussion before the Society for the Study of Inebriety, Tuesday, April 10th, 1906.

* Abstract of Paper read before the Liverpool Medical Institution, March 29th, 1906.

in one case packing was used for a week prior to incision. In operating through the chest wall the abscess was emptied with the aspirator, and its wall pulled up and fixed to the edges of the superficial wound, large rubber tubes were used for drainage, and in some instances the abscess cavity was scraped with a blunt lithotomy scoop and irrigated. In order to show how rapidly the cavities close up, Mr. Newbolt said that eight days after the removal of 50 ounces of pus the cavity would only hold four ounces of lotion. In one case the liver abscess was tympanitic, owing to the escape of gas from the adjoining colon.

THE FATE OF CHEMICAL MATERIAL FOREIGN TO THE BODY IN THE HUMAN ORGANISM.*

By HR. LEWIN, M.D.,

Physician to the Charité Hospital, Berlin.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

It is clear that material introduced into the system is, in a short time, expelled again, either in a changed or an unchanged condition. We have to do with two processes that act on the body, namely, the physical and the chemical, and the fate of such substances introduced has been attributed to such physical and chemical processes. This general knowledge is often veiled by vital views, but we must hold fast to the fundamental principle that a substance introduced into the system will not behave differently from what it does outside the system. At present we have but little insight into the chemistry of the animal body, but what we do possess serves to support indisputably the dictum above expressed. Microscopical anatomy has imparted to us very little as to the essentials of life; the little piecemeal knowledge we do possess we owe to chemical investigation. This imperfect insight into the chemistry of the animal body hinders also our insight into the action of foreign bodies in the organism. The end of a ganglionic cell by means of morphia, for example, is as little understood as the origination of the ganglionic cell itself. We know further, without being at all clear as to the phenomenon, that substances introduced excite the greatest functional powers of the system, and still pass away in the urine unchanged.

We are only in a position to understand the whole of the process when the substance is very simple. For example, we know that sodium bicarbonate when introduced into the stomach becomes decomposed chemically, the carbonic acid is set free, and the sodium unites with the hydrochloric acid. But how the mucus of the stomach is dissolved by the sodium bicarbonate is not comprehensible.

The same with the later fate of iron introduced into the system, even if its immediate fate is known to us. It has been proved recently that the configuration of certain substances, such as the varieties of sugar has an influence on the fate of the further chemical action. Then we know that exudative processes act on the substances introduced; so many alkaloids reach the stage of the latest products, for example, atropine up to 60 per cent., cocain up to 95 per cent. There are

also reducing processes in the system; for example, nitro-benzol that is not attacked in the animal organism is changed by vegetables into amino-benzol. We recognise the simultaneous oxydising and reducing change in the animal body. There is no form of iodine that acts in the animal body in any other way than by the splitting off of the iodine. But besides the oxydising and reducing property for many substances, the organism possesses synthetic properties, yea synthesises at times even with decomposition bodies.

What now have these painful discoveries in regard to the changes in substances introduced into the system gained for us as regards the knowledge of life? Only very insignificant particles; concerning the aim of the processes we know very little. There theory must help us out. There is the intoxication theory that has been much dwelt on. This pre-supposes, however, that the organism is capable of striving according to a regular plan. It is true that it may with an aim, but that is by no means always the case. Thus a combination that takes place in the organism is often without object, and on the other hand a moderate dose of carbolic acid introduced into the system is not poisoned by a mere aimful combination with sulphuric acid. There is here, then, a failure of the organism, it does not work with an aim. In the same way material injurious to the body should undergo the same chemical change into harmlessness, which, however, is not the case. Thus ethyl-alcohol is burnt up in the body. Methyl-alcohol on the contrary is only partly converted into ameisic acid. The latter is, however, far less agreeable for the body than ethyl-alcohol. Another way in which the aimfulness of the body is shown is when a comparatively insoluble substance is converted into a soluble one, so that it can the more readily be excreted. But, for example, the less soluble metallic arsenic is converted in the body into a soluble combination that can exert a destructive power. One cannot call that aimful. From all these facts there results this conclusion, that all the processes of the organism of a chemical nature are independent of its consciousness.

More important than the conversion of chemical bodies in the animal organism is their excretion. In respect of this there are two possibilities:— Either the bodies are excreted within a short time, or they become fixed or deposited. The excretion is, therefore, an aimful process. Life without excretion is impossible. The facts are to be extracted by observation, and these when put together give a greater insight into the processes. The organism strives to get rid of unassimilable bodies as quickly and agreeably as possible. This excretion takes place first through the glands, which by their structure are peculiarly fitted for the office. This glandular activity is very varied, not only that of the different glands, but also that of similar glands from individual to individual. In general one may say that each gland excretes foreign material, introduced in or originating in the organism in proportion to size, its excretion of fluid and its warmth. This excretion takes place when osmotic conditions within the system do not prevent it. The height of the activity is increased by stimulation or pressure. Abnormally placed glands can do more according to their size, but only to a certain degree, not more than that

* An address delivered before the Verein f. Innere Medizin, Jan. 15th, 1906.

for beyond this derangement of the secretion takes place. This fact is of clinical importance, for example in the administration of diuretics.

In association with this stands the question whether all substances pass into all glands, or whether there is a specific attraction in glands for particular substances? The question is answered by pointing to the introduction of nutrient material into the cells. These had a specific power of selection, but this power was not outside chemical laws; there was no place for vitalistic views here. It cannot be different in the case of foreign material so we are driven to the view that certain physical-chemical properties of the body are related to the structure of the tissues. In the lense there is a purely osmotic life. As, however, nutrient material cannot be introduced into the lense by way of experiment, may we speak then of a specific power of selection? No power of selection steps in, for that pre-supposes a will on the part of the cells, and that has not been proved, but it is a product of the given factors. Why, with an equal osmotic equivalent of two substances does only one enter? We have no decided explanation for this, undoubtedly individuality enters in, for example, of the glands. A gland may act vicariously and without any special stimulation. But so much stands fast, every gland when it is healthy takes part in the excretion of the foreign bodies. The reason why a gland does not act with uniformity, but in intervals, lies in this, that another gland has become active. Thus the secretion of the breast is interrupted by vicarious activity of other glands. We recognise two kinds of excretion:—(1) The abrupt rise and fall of excretion; (2) the abrupt rise, the broad shoulder of the curve, and slow fall; thus bromide of potassium takes weeks to get expelled from the system. This fact is of importance clinically. For instance, is dose after dose to be given to produce a rapid effect? Frequently that would not be proper, as the organism has already had to strive to get it out of the system as quickly as possible.

All glands excrete, and so (1) the kidneys. Every substance has a capacity for urination (ist Harnfähigkeit). The substances frequently retain their poisonous properties during excretion. (2) The salivary glands participate in the excretion. That was shown by Ambrose Paré, who records that a patient had a bitter taste in his mouth when bitter material had been introduced into his pleural cavity. We saw the same after subcutaneous injections of quinine, as well as after mercurial inunctions; we also find an intermitting action here. We recalled an earlier custom when patients treated with mercury kept a gold ring in their mouth which became white from mercury deposited from the saliva. The alkaloids also are excreted in the saliva. (3) The stomach also excretes, and so in cases of poisoning from subcutaneous injections of morphia, we find morphia in the washings out of the stomach. Iodine goes into the stomach. If starch is introduced into the stomach of an animal and iodic acid is then injected subcutaneously, the iodine is set free and colours the starch in the stomach blue. A large number of bodies are excreted by the stomach, such as albuminous bodies. Typical poisoning is caused by the wash-out water of the stomach, after poisoning by snake-bite. (4) The intestines

excrete a number of substances, even when the bile has been cut off. Here the glands of both small and large intestine act. This has been proved with certainty with regard to Brunner's glands, but not decisively as regards the crypts of Lieberkühn. The free excretion of the gland of the large intestine is a fact, a proof of this is the facile production of changes in the colour after external dressings of sublimate. (5) The mamma belongs to the excretory glands. It excretes the most heterogeneous substances, such as arsenic after taking Fowler's solution, potassium chromate, mercury, lead, senna, antipyrine, and chloral hydrate. This property is of great importance as regards children fed at the breast, as lead or arsenic may be passed on to an infant from mothers poisoned by these substances. (6) The cuticular excretory glands. Thus, excretion of urea through the skin along with profuse sweating or retention of urine. The skin further excretes iodine, mercury, arsenic and iron. Thus may well be explained the production of exanthems in infectious diseases as the product of irritation from excreted infective material, and the critical sweat be brought into connection with the excretion of injurious substances. (7) Excretion through the lachrymal glands. Thus sharp conjunctivitis has been seen from iodide of mercury after insufflation of calomel into the eye, and the internal administration of iodide. (8) Finally, the lungs excrete gaseous bodies, but not ammoniacal gas, which, on the contrary, is found in the vessels of the lungs. A reason for this peculiar behaviour of the lungs towards ammoniacal gas has not yet been given. Croupous changes even have been seen in the lungs from the internal administration of ammonia. Every mucous surface excretes foreign substances, and in this way salicin is found in the synovia and in the peritoneal fluid.

The deposit of foreign material that has been introduced into the system is of great interest as regards poisoning in parenchymatous organs, through an occupation or trade. Then, for instance, in old lead workers who have long left a lead atmosphere lead symptoms appear for a year and a day when the lead deposited becomes soluble again. I have seen lead poisoning 17 years after a shot in the tibia with healing in of the leaden bullet. What physicians for thousands of years have practised without our scientific knowledge, viz., an extensive unloading or eliminating method of treatment with partial participation of many glands should, perhaps, have clinically more attention devoted to it. Undoubtedly we possess in this method of procedure a rich possibility.

THE OUT-PATIENTS' ROOM.

THE ROYAL EAR HOSPITAL.

Case of Fixation of the Malleus.

By Mr. MACLEOD YEARSLEY, F.R.C.S.

MR. YEARSLEY made the following remarks:—This patient, æt. 41, came here a week ago, complaining that he has been deaf for six years, and that he is worse when he is suffering from a "cold," a trouble to which he is distinctly subject. He does not complain of any tinnitus; his deafness, which used to get well as soon as his "cold" got better, has now "settled in his right ear." Inspection shows that his left tympanic membrane is white and thickened, and the tympano-malleo

lar folds are accentuated. In the right ear the posterior tympano-malleolar fold is seen very prominently, and there is a light reflex below it. The normal cone of light is broken and reduced in size, and there is a small calcareous patch in the anterior segment of the membrane. If we examine carefully with a Siegle's pneumatic speculum, it will be found that the malleus does not move.

Examination of the throat shows a chronic pharyngitis with flabby oedematous uvula and fauces. In the nose there is a deflection of the septum to the right, and a large ledge growing from it at the left inferior aspect.

This man is suffering from a chronic catarrhal condition of the tympanum, complicated in the right ear with fixation of the malleus. This fixation is generally due rather to shortening of the malleolar ligaments than to any adhesion to the inner tympanic wall, although the latter condition may occur. He has come up to-day with a view to mobilising this fixed malleus, a small operation, the results of which are usually very satisfactory. As it is somewhat painful, it is more satisfactory to perform it under suitable anaesthesia, such as may be obtained by means of nitrous oxide gas. The ear having been purified, pressure is made with a modified Luca's probe, tipped with gutta percha, on the short process of the malleus, until the fixation is overcome. Usually there is an immediate improvement in the hearing. The house surgeon, Mr. Jones, has just tested this patient's right ear, with the following result:—The C fork shows that Weber's test is positive for the right ear. Rinne's test is negative, and bone conduction is neither increased nor diminished. The voice is heard at 2 feet 5 inches, the whisper at 8½ inches, and the watch only on contact.

The right ear was then purified with antiseptics, nitrous oxide gas was administered by the house surgeon, and Mr. Yearsley mobilised the malleus. The patient's right ear was again tested some five or ten minutes afterwards, when the hearing was found to be: Voice, 4 feet; whisper, 16 inches; watch, 9½ inches.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

PYLORECTOMY.—MR. BOYCE BARROW operated on a man *æt.* about 50, who had been admitted on account of sickness and pain in the epigastrium. On examination a lump could be felt a little above and to the right of the umbilicus; this was thought to be a malignant growth of the pylorus and an exploratory laparotomy was performed. Finding it possible to remove the malignant mass the operation of pylorotomy was at once proceeded with. Separation of the diseased mass from both the small and the great omentum was fairly easily effected, but the posterior connections of the growth could not be satisfactorily recognised at this stage; therefore the duodenum was clamped and divided and the exposed mucous membrane of this portion of intestine, having been purified and covered, the proximal end was raised so as to disclose the posterior attachments of the growth satisfactorily. These involved the head of the pancreas, and great care was necessary in liberating the diseased mass in this region. The vessels having been tied the stomach was clamped, and the diseased portion, with about a quarter of the pyloric end of the stomach itself was removed. The opening into the stomach was next stitched up perfectly by a double row of sutures, and then a gastroduodenal junction was effected the duodenum being attached on the posterior aspect of the stomach, a fresh opening into the latter having been made. The abdominal wall was finally closed and the wound dressed, no drainage being employed. Although the

whole operation took two hours to perform, the patient's general condition at the end was highly satisfactory, his pulse being quite steady and good, only 80 per minute. Mr. Barrow specially drew attention to this fact, which he attributed to the careful manner with which Dr. Flux had administered the anaesthetic, very little anaesthetic having been used after the abdominal incision had been made, and Mr. Barrow pointed out that all the manipulations within the peritoneum—such as, amongst others, the tedious suturing of the bowel—were not painful, and therefore did not require profound or complete anaesthesia. The shock of an operation was greatly added to, he thought, by the prolongation of complete anaesthesia, and the poisoning effect of large doses of anaesthetics administered. There was, he considered, more shock in very complete anaesthesia, but less when a small quantity of the anaesthetic was administered. He said it might seem extra trouble to close one opening in the stomach and then make a fresh one, but the experience of other surgeons had shown the advisability of this procedure, inasmuch as the liability of leakage likely to occur from imperfect fitting of the duodenum into the original opening into the stomach was obviated.

ST. THOMAS'S HOSPITAL.

OPERATION FOR A COMPLICATED CASE OF IRREDUCIBLE HERNIA.—MR. BATTLE operated on a single woman, *æt.* 43, for a tumour in the left groin. She stated that it had appeared about twelve months before as a small, hard swelling, and had since gradually increased in size; more especially had it increased in size during the last two months; it had not been very painful. The swelling was situated in the position of the inguinal canal. It was pear-shaped, the upper part being hard and evidently solid, whilst the lower part was rounded and fluctuated; the skin about the swelling was very sensitive, but showed no change. There was no impulse on coughing and the tumour was not reducible. On the skin of the abdomen were numerous flattened pigmented moles. The diagnosis made was that the patient had an irreducible hernia, and a hydrocele of the hernial sac. An operation was performed for the radical cure of this hernia, which was supposed to be an oblique inguinal one. An incision was made over the inguinal canal running in the long axis of the swelling; the cystic portion was opened and found to contain blood-stained serous fluid. Above that, however, was a mass of inflamed glands which were matted together and adherent to the abdominal wall above Poupart's ligament, and these had to be separated with the knife from the external oblique. Towards the outer part of the lump a flattened extension was found running over Poupart's ligament into the femoral canal. An incision was made through the outer part of this and carried quite round it; by this means the sac of a femoral hernia was thoroughly opened up, and the omentum, which it contained, separated from the lining of the sac and afterwards from the fundus of the sac, where it was intimately adherent to the glandular mass. By this means the glands and attached omentum were removed, after which the neck of the sac, which easily admitted the forefinger, was ligatured and pushed out of the canal. A radical cure was then performed by the method which Mr. Battle employs for femoral hernia (this has already been described in "Operating Theatres"). Briefly, the outer covering of the inguinal canal was divided from the centre of the external ring outwards for two inches; the pillars of the ring were then clearly defined and Poupart's ligament seen from

above. Immediately above this the transversalis fascia over the femoral canal was divided and as the neck of the sac had been pushed out of the canal, the internal pillar of the ring, with the portion of external oblique continuous with it, was brought down through the slit in the fascia and sutured to the fascia covering the pectineus. Other stitches were also inserted, an outer one fastening the same structure to Poupart's ligament and another one fastening it to Gimbernat's ligament. The internal pillar of the ring was then sutured with its portion of the external oblique on to the external oblique higher up. By this means, Mr. Battle pointed out, any pull was transferred to Poupart's ligament and not to the flap, which had been secured to the pectineal fascia. In the present case two sutures were required to hold the pectineal flap in position; in addition, a reinforcing stitch was placed between the compartment of the femoral sheath lying to the inner side of the vein and Poupart's ligament. The external wound was then closed. Section of the glandular mass showed that some of the glands of which

it was composed were pigmented, and it was very possible, Mr. Battle said, that the glandular change was one of melanotic sarcoma, more especially taking into consideration the numerous pigmented moles which were present in the neighbourhood, although none of these were conspicuous by their size or ulcerated. Mr. Battle remarked that it was somewhat difficult to give the right order of events in the formation of this swelling. The patient herself was not a woman of much intelligence and could not give a very clear account of the exact sequence of events. It was very probable that as the glands became inflamed, and there had certainly been inflammation of them, the one in the femoral canal which had been pushed forwards by the femoral hernia also became inflamed, and the inflammation extended through the sac and caused adhesion of its contents, and when contraction came the hernial sac and omentum were pulled up on to the abdomen and flattened against Poupart's ligament, so as to present no definite swelling which could be distinguished in that situation.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, MARCH 16TH, 1906.

The President, JOSEPH F. O'CARROLL, M.D., F.R.C.P.I.,
in the Chair.

AN UNCOMMON FORM OF RENAL DISEASE.

DR. PARSONS exhibited kidneys which had all the appearances of the congenital-cystic form, only a small portion of the kidney substance being left intact. The patient, a labourer, *æt.* 40, was in his usual good health until the day before his death. Suddenly becoming ill he was admitted to hospital, where he died in twelve hours. Clinically he exhibited symptoms of gastro-intestinal irritation, with suppression of urine. The autopsy revealed nothing amiss except the kidneys shown.

DR. O'CARROLL said it would be interesting to know whether the condition was congenital or not.

Professor SCOTT considered the condition as being of the nature of hypertrophic cirrhosis, due to a pathological change that must have begun within the last ten years at least.

DR. TRAVERS SMITH said that some brain trouble might possibly account for the sudden death of the patient.

DR. PARSONS said the brain was examined, and was found normal. He considered it to be more a case of congenital cystic kidneys than of chronic interstitial nephritis.

AORTIC ANEURYSM PERFORATING PULMONARY ARTERY AND CAUSING PERFORATION OF PULMONARY VALVE.

Professor O'SULLIVAN said the patient from whom the specimen was taken was brought in a dying state to hospital. The *post-mortem* showed an aneurysm of the aorta on the right side, half-an-inch above the attachments of the valves, and perforating the pericardium. It had also perforated the pulmonary artery above the valves, and the valves themselves showed evidence of perforation. This latter condition, he said, was caused by the blood-stream that had passed from the aorta into the pulmonary artery.

DR. O'CARROLL mentioned a case, almost identical, that had been shown him by Dr. Earl, but he was not certain as to the involvement of the valves.

EPITHELIOMATOUS PENIS.

Mr. E. H. TAYLOR exhibited a penis removed for epithelioma.

EPITHELIOMA INVOLVING PART OF THE DUODENUM WHERE THE BILE-DUCT OPENS INTO THE INTESTINE.

Mr. E. H. TAYLOR said: The man, *æt.* 40, had several attacks of jaundice, which gradually disappeared after each attack. When he came to hospital his liver was somewhat enlarged, and his skin slightly jaundiced. On opening the abdomen the gall-bladder was distended, and a great number of gall-stones were found in the common bile-duct. Found a hard mass in the duct where it opens into the duodenum, which he removed. On the ninth day the patient's temperature rose and he developed pneumonia, from which he died. Dr. O'Sullivan made the *post-mortem*, and found a cancerous mass at the mouth of the duct. There was no obstruction to the flow of bile, and the liver was enlarged and cirrhotic.

CANCER OF THE OVARY.

Mr. E. H. TAYLOR said: This tumour was removed from a woman, *æt.* 55. On examination it seemed like circumscribed peritonitis, and could be felt just above the pelvis. The tumour was more easily palpated when the patient was under the anæsthetic. On opening the abdomen a quantity of bloody fluid poured out. The patient would be able to leave hospital the following week.

DR. O'CARROLL said the jaundice in the case of the epithelioma of the duodenum was due to the gall-stones, and not to the cancer.

Professor O'SULLIVAN said the duodenal epithelioma resembled a papilloma in many respects. As to the development of pneumonia, it was interesting to note that the diplococcus of pneumonia was found in the bile duct before any trouble appeared in the lung. It was held that croupous pneumonia did not originate from the blood, but through the air passages. It was probable in this case, however, that the diplococci might have reached the lung by extension from the under surface of the liver through the diaphragm.

URTICARIA PIGMENTOSA.

DR. WALLACE BEATTY exhibited a boy, *æt.* nearly 4, the subject of urticaria pigmentosa, dating from a month after birth, and he showed microscopic sections of a nodule excised from inside the knee. He demonstrated the interesting fact that the granules of the mast-cells, which are stained red by polychrome methylene blue in alcohol—fixed and hardened preparations—are stained also by eosin if the skin is fixed

in Zenker's fluid (*i.e.*, Muller's fluid saturated with corrosive sublimate plus 5 per cent. glacial acetic acid) before final hardening with alcohol. Three considerations present themselves—(a) Has Zenker's fluid so altered the granules of the mast-cells as to render them acidophilic instead of basophilic, as they appear to be when alcohol alone is used for fixing and hardening? (b) Are the granules of the mast-cells really basophilic? If the red colour of these granules is due to the methylene azure of the polychrome methylene blue, it is to be noted that methylene azure is an oxidised methylene blue, and contains the SO_2 group—*i.e.*, a less basic body than the methylene blue from which it is derived. (c) Perhaps the true explanation of the red colour of the granules of the mast-cells, when the sections are treated with eosin, followed by Löffler's methylene blue, is that these granules are really stained by methylene azure. Nocht and Robin (*c.f.*, Mann's Physiological Histology) found that on bringing methylene blue and eosin together there is formed methylene azure along with other compounds. If so, the stain is practically the same as if polychrome methylene blue were used. However, the fixing agent is not without some influence, as the mast-cell-granules in sections made from the portion of the skin fixed in Zenker's fluid do not take the characteristic red colour, but a bluish colour, with polychrome methylene blue.

Dr. O'CARROLL said there were two fundamental theories regarding the origin of this disease—*viz.*, that it is either (1) a structural or anatomical lesion, or (2) a chemical one.

Professor SCOTT said on examining the blood he found the lymphocytes existed in almost equal amount with the polynuclear leucocytes. The granules were of a proteid nature, and would be acted upon by reagents. They would be altered by such chemicals as corrosive sublimate.

Dr. WALTER SMITH thought it not improbable that in the near future, the closer study of stains and dyes might throw some light upon the important problem of the nature of proteid substances. He pointed out that an efficient stain usually included or was made up of three constituents:—(1) a nucleus, or chromophore, with a feeble acid or basic tendency. The chromophore usually belongs to the aromatic series, and includes polyvalent atoms—*e.g.*, C : O : S : N. (2) Auxochromes, represented by NH_2 (basic group), or (OH), and oxygen (acidic radicals), tacked on the chromophore, and, correspondingly, modifying its properties. (3) Salt-forming groups—*e.g.*, carboxyl, COOH : sulphonic group HSO_3 , NOH : NO_2 .

This may be represented diagrammatically:—

The general theory of staining depends upon physico-chemical interactions between the stain and the tissue.

Dr. O'BRIEN said that any side-light that could be thrown on the pathology and etiology of the disease would be productive of good results as regarded the treatment and diagnosis.

Dr. WALLACE BEATTY briefly replied. He said—Some thought urticaria pigmentosa might possibly be of congenital origin, like naevi. The child he exhibited was in the stationary phase of the disease; and he had never seen a further advanced case. In his experience he had only met with two cases in the early stage.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, MARCH 29TH, 1906.

FRANK T. PAUL, F.R.C.S., President, in the Chair.

THE DIMINISHING BIRTH-RATE.

DR. HUGH R. JONES read a note on the diminishing birth-rate. Although artificial means of preventing conception were being more generally and systematically adopted, it must be remembered that families had always been limited by prudential self-restraint to an extent not generally realised. The influence of the later age at marriage and the lower marriage-rate and of the employment of women in intellectual and industrial occupations was being under-estimated. The death-rate had also fallen, and this fall began before the fall in the birth-rate. The former was due in part to the high birth-rate in former years, but it also indicated an improvement in the social condition of the population. Improvement in the social status was always attended by a fall in the birth-rate. The natural increment of the population was still high. The low death-rate was masked and compensated for by the low birth-rate. It was to be regretted that, except in 1904 and 1905, the rate of infant mortality had been persistently high. He hoped that the present low birth-rate was only a temporary phase in the history of English civilisation. For a high birth-rate and a robust young population were necessary to continue the past policy of England. The growth of the population of a country depended on the sustained systematic policy of the mass of the people, which was guided by the action and teaching of the educated classes, and upon them was the responsibility.

Dr. COLIN CAMPBELL attributed the decreasing birth-rate among the working classes to the creation of the lower order of practitioners in midwifery. They had been taught the use of the uterine sound—with "strict antiseptic precautions"—and they utilised the knowledge. The *Lancet* had recently directed attention to advertisements of "preventives" in journals such as *Myra's*. He had exhibited, some years ago, samples of preventives sent to a midwife to retail to her patients.

Drs. W. Macvie, Moffat, and G. C. Walker also spoke.

THE OPERATIVE TREATMENT OF UTERINE FIBROMYOMATA.

Dr. T. B. GRIMSDALE read a short note on the operative treatment of fibroid tumours of the uterus, and pointed out the wonderful improvements that had been made in abdominal hysterectomy of late years, and contrasted the mortality at present with that of ten years ago. He also showed that the mortality from operation was now less than that of the disease.

Dr. H. BRIGGS thought the present safety of abdominal hysterectomy in the treatment of fibroids at an early stage was an encouragement to the gynaecologist, but the operation could be often declined to the patient's advantage.

Sir JAMES BARR exhibited Dr. Oliver's new hæzma-nometer.

Mr. G. P. NEWBOLT read a paper on "Tropical Abscess of the Liver," which will be found on page 391 of the present issue.

Mr. K. W. MONSARRAT spoke of the difficulties of the evacuation and satisfactory drainage in cases where the abscess bulged directly downwards from the under surface of the right lobe at considerable depth from the anterior abdominal wall. He considered that an incision below the twelfth rib in the loin was the only route for satisfactory drainage under such circumstances. He mentioned the case of a woman who had always lived in Cheshire on whom he had operated for a single abscess in the right lobe; there were no symptoms of any intestinal disorder, there was no fever, the pus was sterile bacteriologically, but contained amœbæ in large numbers.

The following members also took part in the discussion:—The President Drs. T. R. Glynn, H. W. Carter, Nathan Raw, R. J. M. Buchanan, C. J. Macalister, J. Lloyd Roberts.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

CLINICAL MEETING HELD ON FRIDAY EVENING,
APRIL 6TH.

Under the Presidency of Mr. L. A. BIDWELL.

The following cases were shown:—

By Mr. HOWELL EVANS: Two cases of Congenital Pigmented Wart (Acanthoma), remarks on these cases were illustrated by a series of lantern slides.

By Dr. ARTHUR SAUNDERS (for Dr. Seymour Taylor): Two cases of *Tabes Dorsalis* in women.

By Dr. PHINEAS ABRAHAM: A case of *Dermatitis Erythematosa* which commenced as an irruption indistinguishable from *Pityriasis Rubra Pilaris*; an infant the subject of several *Cornua Cutaneum*, and a case showing an unusual form of *Impetigo Contagiosa* which has sometimes been designated *Impetigo Annulata*.

Dr. ARTHUR SAUNDERS showed a case of *Sclerodermia* involving a localised area on the back, which had followed, and appeared to be the result of an injury; a case of syphilis in a man, with great enlargement of the skull and also of the liver; and a child of 12 with greatly enlarged head and spleen, the result of hereditary syphilis.

Dr. DONALD ARMOUR exhibited a woman from whom he had removed a large polycystic kidney sixteen months before; the specimen was shown at the same time; the patient was in perfect health; he also showed a patient for whom he had excised both temporo-maxillary joints for bony ankylosis some months previously, with a very satisfactory result.

Dr. LEONARD DOBSON showed a case of *Epithelioma of the Auricle*.

Mr. E. PERCY PATON: A case of well-marked *Mollusum Fibrosum*.

Mr. ASTLETT BALDWIN: A case of *Hereditary Ataxia* with marked deformity of both feet.

Mr. L. A. BIDWELL showed a case of *Rodent ulcer* in which the ulcer had developed in the situation of an old syphilitic. There was a large attendance of members of the Society, and an interesting and instructive discussion followed the exhibition of the cases.

ULSTER MEDICAL SOCIETY.

MEETING HELD IN THE MEDICAL INSTITUTE, BELFAST,
THURSDAY EVENING, APRIL 5.

The President, Dr. WILLIAM CALWELL, in the Chair.

Dr. CECIL SHAW showed a case of *Myxo-sarcoma*, involving the nasal cavity, the antrum, and the orbit on the right side, and demonstrated the extent of the growth by transillumination. The patient was a woman, *æt.* 45. A section of the growth was showed under the microscope.

Professor SINCLAIR described three cases of successful nephrectomy, and showed the diseased kidneys. In case 1, the patient was a woman *æt.* 24, and the right kidney was affected with a lympho-sarcoma. There was a great trouble in removing it, owing to adhesions. The operation was done by the transperitoneal method. The kidney, when removed weighed 2½ lbs. The clinical interest of the case lay in the fact that there had been painless hæmaturia two and three-quarter years ago, so that the growth must have begun before that time. Such cases have been known to last for ten or twelve years. The urine was normal, except when blood was present. For five out of the first twelve months the patient was confined to bed by the hæmaturia, but there had been complete freedom from it for the past year. Case 2 was one of carcinoma, and was much more rapid and with more pain. The patient was a woman, *æt.* 41, and the right kidney was diseased. She was aware of a tumour for four months before operation, movable at first, with pain and bleeding for the last three months. The kidney was removed through a lumbo-abdominal incision, and a large part of the fatty capsule was

removed with it. The mass measured 9 by 5 by 3½ inches. The patient did well, and left hospital in a month, and had over a year's respite. The mortality in this operation used to be 70 per cent., but was now reduced to 20 or 30 per cent., and this improvement was probably partly due to our now being alive to the necessity of speed in operating, since ether and chloroform both have a bad effect on the kidney. He preferred the anterior route in cases where the kidney was large and adhesions were present. Case 3 was a caseous tubercular kidney of long standing. It was the left kidney in a man, *æt.* 38, and when removed weighed 3 lbs. It was a pure caseous deposit. The man knew he had a tumour for ten years, but there were no urinary symptoms and no tubercular symptoms elsewhere. Symptoms of intestinal obstruction occurring in a rather acute form on several occasions were the only symptoms present. It was a remarkable thing that there was no mixed infection, and all the more so as the patient was liable to attacks of boils, so the micro-organisms were ready on the premises. The operation was by the transperitoneal route, and was not nearly so difficult as the cancers. After a year there is no sign of other trouble; the man has put on weight, and is at business every day. In all these cases prolonged vomiting gave the greatest trouble, lasting for three, five or seven days. It was an interesting question whether this was due to uræmia or some other toxæmia.

The cases were discussed by Messrs. Mitchell and Fullerton, and Drs. Calwell, McKisack and Fielden.

Dr. H. L. MCKISACK read a paper on

ALBUMINURIA.

He said that he would confine himself to the diagnostic value of albuminuria. There were two main groups—(1) Where the urine rises free from albumin and gathers it on its way; and (2), where the albumin is secreted with the urine. In the first group an admixture of pus with the urine was generally the source of the albumin. The most interesting to the physician was that form of pyelitis sometimes seen in young female children due to infection with the *bacillus coli*. The second group included most of the forms that are of constant interest to the physician, and might be considered in three sub-groups:—(a) Physiological or functional albuminuria, so-called. Many varieties are described: hyaline casts occur in all, but there are no cardio-vascular signs. These cases are of great interest in connection with life insurance. Professor Saunby would pass many of them, and Professor Wright says that to consider these as pathological is one of the antiquities of medicine. Till further light is forthcoming on them, Dr. McKisack would be inclined to say that albuminuria of renal origin denotes some change in the normal epithelium. A certain proportion of these cases ultimately develop nephritis. (b) In the second sub-group there is some disease of another part, but no nephritis. The renal epithelium is slightly affected, as in febrile disease, lead poisoning, and various nervous lesions. In all these it seems to be temporary. (c) The third sub-group includes the more serious affections of the kidney—congestion and real nephritis. These cases cannot be clearly cut off from those in the last sub-group, for a slight febrile albuminuria may occur in scarlatina, and run into a true nephritis, or in pregnancy there may be a mechanical albuminuria which runs into a more serious form. There is a large margin of safety in renal secretion, so that there may be no evidence of the morbid condition, except the albuminuria, a sort of compensation somewhat analogous to what occurs in cardiac disease, hiding all symptoms except on special examination. The small red kidney is not a nephritis at all, but a form of arterial degeneration. The name, gouty kidney, is only half a truth; granular kidney is not correct, for other forms may be granular too, and chronic interstitial nephritis is a name to avoid. It might be called chronic arterial renal sclerosis. Dr. McKisack concluded his paper by a brief résumé, showing how the various forms of albuminuria might be divided either according to the quantity of albumin

usually present, or according to the source of the albumin.

The paper was discussed by Drs. Trimble, Sinclair, Houston, Robert Campbell, and the President. Dr. Houston defended Professor Wright's views on physiological albuminuria, and described the effect of treatment by calcium chloride on many of these cases. In replying, Dr. MCKISACK said that he thought that the presence of albumin showed at least a certain vulnerability in the renal epithelium.

GLASGOW EASTERN MEDICAL SOCIETY.

MEETING HELD WEDNESDAY, MARCH 4TH, 1906.
Dr. T. BARNES, Vice-President, in the Chair.

Dr. J. K. KELLY read an interesting and lucid paper on

STERILITY,

and dealt with the subject chiefly in regard to women. He pointed out certain anatomical considerations, such as the proper position of the os uteri, lying on the posterior vaginal wall, and how flexions, and displacements of the womb tend to displace the natural position of the os, as well as indirectly to set up secondary inflammatory changes inimical to conception. Three conditions, he said, were necessary for impregnation: 1, healthy ovum; 2, healthy spermatozoon; 3, healthy state of the mucous membrane of the uterus. Dr. Kelly pointed out that there was a circulation of peritoneal fluid through the Fallopian tube to the uterus, which carried, like a tide, the ova to meet the spermatozoa, which had to swim up stream. Any mechanical hindrance interfering with the union of these elements would be a bar to pregnancy. It was important to see that there was no impediment, such as atresia, elongated and stenosed os, with endo-metritis. Pyosalpinx, by bringing about adhesions of the fimbriated mouth of the Fallopian tubes, generally brought about sterility.

Dr. Kelly laid considerable stress on operative interference with the cervix and the endometrium, by amputation and curretting, in case of stenosed and elongated cervix with endo-metritis.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD. FRANCE.

Paris, April 7th, 1906.

SUTURE OF THE HEART.

At the meeting of the Société de Chirurgie, M. Querin communicated two cases of wounds of the heart. In the first case, the wound was produced by a knife. M. Querin opened the thorax, evacuated the blood from the pericardium, and discovered a wound in the left ventricle, which he sutured. The patient made a rapid and complete recovery and left the hospital on the thirteenth day. The second case was treated by M. Savariand; the wound, produced by a stiletto, was situated in the right ventricle. The part was sutured two hours after the accident, but the patient succumbed on the fourteenth day from infection of the pleura.

Wounds of the pericardium and the heart are divided into penetrating and non-penetrating. Non-penetrating wounds, says Terrier, concern the muscular fibres and the vessels, and have been observed several times. The wound frequently bleeds abundantly producing compression of the heart, which, if not relieved by opening the pericardium, renders the prognosis particularly grave.

Of all the non-penetrating wounds of the heart, the most important are those which concern the coronary arteries. However, the lesion is not absolutely fatal as in some rare cases spontaneous cure has been observed, but more frequently the patient succumbs

to hæmorrhage and the resulting compression of the heart.

Penetrating wounds of the pericardium and the heart are much more frequent, and here also the prognosis is not necessarily fatal; wounds produced by a pointed instrument are less grave than those produced by a knife or a bullet. Wounds of the auricles are the most dangerous, as the hæmorrhage is very abundant and immediate.

Wounds of the heart, without opening the pericardium, are rare; they are never produced by sharp instruments; they result from fire-arms, contused wounds, and traumatic ruptures.

An interesting fact in connection with heart wounds is the rapidity with which they become cicatrised. M. Tillaux relates a striking example. A lunatic introduced into the region of the heart a piece of wire about five inches long. When M. Tillaux saw him, the foreign body had disappeared, but it could be felt by the fingers rising up and down with the rhythm of the heart. The circulation was by no means disturbed. Thinking that the piece of iron was acting as a plug, he did not dare extract it, and the following day it could not be felt; the patient recovered completely. He died, however, the following year, and at the autopsy the wire was found to have gone through the anterior border of the left lung, the posterior wall of the ventricle, and become fixed in the right lung. In another case a bullet was found encysted in the ventricle.

Launay cites the case of a revolver bullet which had traversed the heart, entering by the left ventricle a little above the point and came out by the same ventricle, but higher up. The patient recovered completely after suture of the heart.

The symptoms of wounds of the heart are sometimes deceptive. They depend on the gravity of the wound, the importance of the hæmorrhage, and the consequent compression, and also on the nerve troubles due to a lesion of the ganglions of the heart.

Sometimes the general condition of the patient is almost normal, but more frequently he is pale, plunged in a state of anguish and prostration, and becomes rapidly cold, or he falls into prolonged syncope and succumbs. According to Fischer, syncope was observed in 87 of 452 cases published. The hæmorrhage as a consequence of the wound may be both external and internal; the former is generally insignificant, but the latter is very grave, for obvious reasons. The signs of compression of the heart are: precordial anguish, cyanosis, smallness and rapidity of the pulsations. Percussion reveals an increase of the normal dullness, and by auscultation the beats are found to be muffled. Respiratory disturbance is constant; dyspnoea, passive pulmonary congestion, and, when the lung and the pleura are wounded, hæmoptysis or pleural effusion may be observed.

According to Fischer, 18 per cent. of wounds of the heart recover, and 51 per cent. when the pericardium alone was concerned.

The treatment of wounds of the heart is both medical and surgical. In a certain number of cases medical treatment suffices, which consists in absolute rest, in order to encourage the formation of the clot and to prevent it from becoming detached. The patient should be kept in a half-sitting posture to make breathing more easy, and to prevent pulmonary congestion. Cardiac agents—digitalis, caffeine, &c., are absolutely counter-indicated as well as injections of serum.

The Surgical Treatment.—It is not many years since surgical interference in wounds of the heart was considered possible. Pegrol and Block said in their classical works that the surgeon was disarmed before cases of the kind. To-day the treatment of wounds of the heart may be regarded as one of the finest conquests of modern surgery, as by an early operation a patient otherwise condemned may recover.

The first thing recommended to be done in wounds of the heart is to close the orifice antiseptically. Later,

if there be signs of compression from hæmorrhage into the pericardium, it should be evacuated by tapping. To suture the cardiac wound, a "shutter" is made over the region by an incision in the form of the letter U. According to Foutau, the incision commences in the third intercostal space near the anterior axillary line, and following the upper border of the fourth rib, it is brought to the border of the sternum, and descends parallel to that bone to the sixth cartilage, and extends outwards to the sixth intercostal space. The fourth, fifth, and sixth cartilages are cut across close to the sternum, and by cutting through the ribs, the shutter can be thrown back, bringing into view the pericardium.

GERMANY.

Berlin, April 7th, 1906.

At the Freie Vereinigung der Chirurgen, Hr. Rinne showed a young man who had been brought to him on account of

EXTREME SWELLING OF THE RIGHT FRONTAL BONE. Six years before he had had an injury to the part, after which the swelling had come on gradually. He suffered from extreme congestion of the whole of the left side of the head, and with such severe headache, coming on at intervals of some weeks, that he was unable to follow his employment, and begged urgently for relief. The speaker decided to chisel out the frontal bone, and came down in doing it upon a sclerosed bony mass about 8 cm. in thickness, and which he cut away down to the dura mater. Below this nothing pathological was found. The wound healed by granulation without the deformity returning, and the patient again became fit for work. The operation was performed two and a half years back, and the patient still felt quite well. There was no tumour in the ears, but simply a sclerosed bony mass.

Hr. Borchards said that under a similar thickening of the frontal bone he had found a small angiosarcoma of the dura mater. The subsequent course in H. Rinne's case excluded such a condition as that.

At the Verein für Innere Medizin, Hr. v. Leyden related a

CASE OF CHALKY METASTASES IN THE HEART AND OTHER ORGANS.

A servant-girl, æt. 19, was admitted into the klinik on January 10th, 1906. The patient had felt ill for some days, complained of tearing and dragging in the limbs, she had slight fever and the joints were somewhat swollen. A diagnosis of articular rheumatism was made, and the patient put on salicylic preparations. She felt better after this, but exhibited a peculiar stupid behaviour. She soon took to bed again, and when desired to remain up opposed this with a certain passive resistance; the stupidity became more pronounced; she complained of violent dragging in the extremities. Examination showed leucorrhœa in which there were no gonococci. Then left-sided paralysis of the abdomen came on; over the heart a systolic murmur was audible. Then serious symptoms appeared, violent headache, dragging in the feet and arms, but no other disturbance of mobility. The sensorium, with the exception of the stupidity, remained free. In the following days excessive vomiting took place, with increasing headache, and soon afterwards the patient was found dead in bed one morning. No decided diagnosis could be made; endocarditis with cerebral complications, was thought of &c. The autopsy revealed a condition that could not have been diagnosed. Sarcomatous infiltration of the surface of the brain. The skull covering showed extreme porosity and atrophy, the inner lamina was perforated in numerous places, and sarcomatous tissue was found in the cavities. The heart was small and flaccid, the auricle, especially the left, infiltrated with bony, hard masses that proved to be chalky infiltrations; there were also similar infiltration in other parts of the heart. Nearly all the internal organs showed similar infiltration, but not to the same extent; the kidneys, lungs and stomach.

The cerebral condition could not have been diagnosed from the symptoms, especially as the fundus oculi was normal. The course of events was this, therefore: The sarcomatous tumour had caused partial resorption of the bony skull, the lime constituents had become softened, and been carried into the blood current and had caused the metastases. It was remarkable that the sarcomatous layer, which had caused no special pressure in the brain, had caused absorption of bone where, from higher pressure from other causes, such a condition had scarcely ever been observed. The malignant tumour, therefore, exerted an especially powerful specific action.

Hr. Davidsohn drew attention to the microscopical preparations. He had seen a similar case six years ago. In that case three organs showed the metastases: the lungs, the kidneys and the stomach, and in that case, as in the present, only in the middle glandular layer. In the present case the heart was affected also. Anatomically there was no visible reason for the excessive deposit. The growth of the tumour into the skull was peculiar. There could be no internal cerebral pressure, as the tumour was situated exclusively outside the dura mater.

Hr. Plehn related

TWO CASES OF LEUCÆMIA.

The first case was that of a girl, æt. 15, very much emaciated, having an enormously spleen. The leucocytes consisted mainly of myeloblasts; there were also nucleated red blood corpuscles. Röntgen ray treatment was instituted. Even in the course of a few weeks a considerable diminution in the size of the spleen was effected and also in the number of the leucocytes, whilst the erythrocytes increased to 5,900,000. The body-weight had increased by 6 kilos, the enlargement of the glands and the albuminuria had disappeared. The spleen had at last contracted to the size of the fist, where at first its length was 37 cm. and its breadth 35 cm. A dermatitis was caused at first by the X-rays, but later on this ceased. The patient now felt well, and the improvement was attributed to the X-ray treatment.

The second case was that of a very much emaciated woman, æt. 76. She had felt weak for four weeks, and for three had had no appetite. A week ago she had hæmorrhagic spots on the haunch. There was no enlargement of either spleen or glands. Examination of the blood showed almost pure myelocyticleucæmia, (numerous small medullary cells). Two days after admission the patient became suddenly somnolent, and died from multiple cerebral hæmorrhages. The case might be taken as a proof that every leucæmia proceeded from the bone marrow. The disease had lasted so short a time that secondary changes in the lymphatic apparatus had not had time to develop.

Hr. Brenda observed that there were no other leucæmia disease of organs than that of the bone marrow.

AUSTRIA.

Vienna, April 7th, 1906.

NOMA OF THE CHEEK.

EISELSBERG exhibited to the members of the Gesellschaft, a young girl, æt. 10, who developed a noma on the cheek that involved the bony structure of the jaw also. The child had always been healthy and took typhoid in her seventh year, after which the noma rapidly developed, destroying a large portion of the cheek.

She was received into hospital two years ago in a hopeless condition, as shown by a photograph. Bart's apparatus was first applied with the hope of binding the bony structure of the joint but without effect.

The defect in the cheek was next tried. A flap was taken from the breast and turned up on the opening and the defect restored in the soft tissue. Nothing remains but to try a prothesis to restore the continuity of the bony structure.

PARALYSIS THROUGH MUSCULAR COMBINATION.

Gersuny presented a patient in whom a peculiar

phenomenon in plastic operations occurred—viz., the deltoid and trapezius. He found it necessary to take a flap from the deltoid for the face. After the deltoid healed he found it paralysed from loss of innervation.

He thought this could be corrected by another operation which he performed on a man, *æt.* 40. This patient commenced with great pain in the region of the right shoulder without swelling or pain in passive movement when received into hospital. He had no power to move it himself.

Hochwart examined him on February 23rd, 1905, and found all the cerebral nerves healthy and normal, but the right deltoid muscle quite atrophied, while the supra and infra-spinati were flat; the right arm was weaker than the left, and he was unable to raise the hand and arm to the level of the shoulder, although he was able to rotate and abduct it. All the other muscles seemed to be normal. Corresponding with the insertion of the nerve in the deltoid was a hypo-æsthetic and algesic zone. Faradic current was lost, but slight contractions were obtained by the galvanic.

On May 6th, 1905, abduction and rotation of the right shoulder was quite lost, while the infra and supra-spinati were distinctly atrophic. The defective sensibility was still present, and the electric condition unchanged.

On June 10th, Hochwart determined to operate by making an incision from the front of the neck over the middle of the acromion outwards, freeing the attachments of both the trapezius and deltoid. The acromion with the lateral part of the spina scapulae were removed with the chisel. The tendinous insertion of the deltoid was removed and its cut end inserted into the lower surface of the trapezius, for which purpose the arm had to be raised and supported in that position during the process of healing. The parts were well kept together with stitches, and care taken to prevent adhesion to the scapula. The wound was closed and healed up in eleven days. In fifteen days the bandages were removed and electric treatment commenced to the deltoid. On the twenty-first day after the operation the patient was dismissed with advice to continue the electric treatment. He returned in September, three months after the operation, slightly better in the movement of the arm. With more energetic movement he was able to lift his arm to the level of the shoulder by the end of the month. By the end of November he was able to perform all the natural movements with perfect ease and freedom but lacked in strength.

On February 20th, of the present year, Prof. Hochwart again examined him, and found the right arm about half a centimetre less than the left; deltoid slightly atrophic; trapezius slightly weaker than the left. Movements in right arm perfect, but all much weaker. Tactile sensibility and feeling of pain normal. Contractions strong in trapezius, nothing from brachial plexus. Faradic and galvanic current, acting on accessories, contract trapezius violently on both right and left. The axillary nerve, when stimulated; does not affect right deltoid with either current, which shows that the innervation is through the accessory nerve which justified the operation.

Hochwart remarked that it was an error to conclude that no motor power was present in a nerve when no current activity was demonstrated. There are cases on record where no electric phenomena could be obtained in muscles, yet the motor activity was perfect.

HUNGARY.

Budapest, April 7th, 1906.

At the recent meeting of the Budapest Interhospital Association Dr. Tuszka Odón reported the case of a woman, *æt.* 28, who had an attack of typhoid fever seven years ago, accompanied by hæmorrhage from the bowel and vomiting of blood, followed by phlebitis of both lower extremities, and nausea and vomiting occurring three or four times a day and induced during the latter time, not only by taking food but by nervous excitement. These were worse near the menstrual period. During the seven years she

had subsisted mainly upon infant's foods, and had undergone various treatments, including rest, lavage and dilatation of the uterus, the latter being followed by some temporary benefit. Upon admission to the hospital, the right kidney was found to have descended to the level of the umbilicus, replacement of which and the removal of the left tube, ovary and appendix was followed by complete recovery.

Dr. Müller Vilmos, speaking on EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS.

said it was his opinion that the profession must go back to old and well-tried methods—clinical history and physical examination—in making the early diagnosis of this disease. Of the newer methods, sputum examination does not inform early enough, tuberculin may give a reaction when no active tuberculosis is present, and may fail to give a reaction when active tuberculosis is really present. While the X-rays may confirm what physical examination has already discovered, it does not reveal anything that cannot be ascertained in other ways. Sources of error in diagnosis may be set down as three: (1) Preconceived ideas—the physician's mind is made up beforehand that the patient has or has not tuberculosis. (2) Inattention to details, the changes that are dealt with in the early stages of tuberculosis are slight, and there are many little things that by themselves mean nothing, but put together mean everything, that in a diagnosis must be reached. (3) Lack of persistence in the examination is often at fault. One investigation is not sufficient, and the evidence must be gone over several times.

Dr. Koranyi Sandor discussed the subject, whether increased molecular concentration of the blood warrants a diagnosis of bilateral kidney disease? He had a case of carcinoma of the left kidney, with the right perfectly normal and a freezing point of the blood 0.635°C. He believed that this concentration of the blood, in spite of the efficiency of the right kidney, was caused by the suddenness with which the additional work was thrown upon it through the rapid growth of the tumour of the other kidney. He concludes that unilateral kidney disease (excluding other causes) can exist together with increased molecular concentration of the blood, and that it is not justifiable in cases in which a lesion of one kidney can be proved, to conclude that the other organ is also diseased, because the molecular concentration of the blood is raised.

DEFECTIVE VACCINATION LAW.

Decision in a case of a physician accused by the State Health Committee of issuing a false vaccination certificate has freed some hundreds of the same charge. The certificate was based on a vaccination of a child of four years, the mother stating it had been successful; it appears not to have been. The magistrate censured the physician for carelessness in giving the certificate, but could not hold guilty of violation of the law, as no time limit is specified. The decision will probably result in legislative amendment of the act relating to vaccination.

LETTERS TO THE EDITOR.

INSURANCE WITHOUT MEDICAL EXAMINATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The medical profession and the public should be alike grateful to you for having taken up the above subject in your usual straightforward fashion. It is time someone spoke out on this barefaced attempt to deprive medical men of their just rights. The manager of the Sun office actually sends a circular to the medical profession boasting how he has outwitted them in the case of 7,500 applicants who have been insured in his office in a single year without medical examination. That is seething the kid in its mother's milk with a vengeance! However, it is comforting to reflect that out of that number a certain percentage are bound to be afflicted with deadly disease that can

be detected only by skilled medical experts. Everyone versed in insurance work knows that a sound medical adviser saves them scores, or, it may be, hundreds of thousands of pounds in a single year. I myself know of a case where a referee rejected an applicant who had been insured by another company a year before. That applicant died within three years, and the company was saved several thousand pounds. But the attempt remains to make money at the expense of medical men, and to delude the public by a system that proffers non-medical admission in substance, but not in fact. The medical profession and the public will, I trust, be kept reminded of the facts of the case by your able and fearless attitude.

I am, sir, yours truly,
A COUNTRY REFEREE.

THE FORTUNES OF QUACKERY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Referring to your articles on quackery, it may not be uninteresting to your readers to learn that the maker of "Pink Pills for Pale People," to which you have on more than one occasion referred, has recently died, leaving property to the value of £1,311,000. This individual, George Fulford by name, twenty years ago, kept a small chemist's shop. Among his customers was a country doctor who was in the habit of making up for his patients an iron pill with a pink coating. His patients had firm faith in the merit of his pills, and he was quite unable to cope with the demand; so he sent the recipe to Mr. Fulford, and directed his patients to that druggist's shop. This induced the chemist to advertise, and the money so spent came back to him many times over in orders for pills, until a short time ago, when he was fatally injured in a motor-car accident, and his estate was found to be worth this enormous sum, made from a country doctor's prescription coupled with his own enterprise. Truly, quackery spells riches, and honest practice not infrequently poverty.

I am, Sir, yours truly,
A PRACTITIONER.

NEWSPAPERS AND QUACK ADVERTISEMENTS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The campaign you have started has done much good. The pages of at least one first-rate paper, the *Tribune*, have been purified in consequence of the exposure you have made of the infamous character of the quack medicine trade. It seems, however, hopeless to expect anything like full success so long as the leading papers show so bad an example. It is especially deplorable to see the *Times* continuing to admit the advertisements of men repeatedly denounced in the very strongest terms by its editors within recent years. The *Times* has upon its staff, either permanently or as occasional contributors, distinguished members of the profession well able to advise the manager in this matter. It is grotesque to read an able series of articles on "Infantile Mortality" in which the part played by the dosing of infants with "soothing" mixtures as a lethal factor is exposed, whilst at the same time quack preparations of this class are largely advertised in the paper. How many innocent mothers have been led to depend upon fraudulent nostrums with fatal results by such advertisements? The fact that they appear in the *Times* is enough with simple readers to establish the truth of any plausible statement the advertisements may contain. Then there are the *Telegraph*, the *Morning Post*, and the *Daily Mail*. Each of these papers is owned by a Peer of the Realm. Each of these noblemen has gained his position through his journal. Their wealth has been accumulated by the same means. They ought not to stoop to augment their incomes by helping, however remotely, in a traffic so cruel and cowardly as that upon which you have thrown so clear a light. If these noble proprietors of great organs that take upon themselves the role of censors of public and private morality do not realise the infamy of

medical quackery, if they are not aware of the misery to which the quack medicine trade gives rise, they can easily ascertain the facts by inquiry, and your articles have shown them at any rate their duty in this latter respect. It seems to me that from the mere point of view of money-making it would pay these papers to exercise the strictest supervision over their advertising columns. If it were known that no advertisement which could be legitimately objected to would be allowed to appear in the paper a large number of advertisers of the better sort would surely be attracted. Many of these must object to the publication of their announcements in juxtaposition to those of blatant impostors and knaves. If the *Tribune* can, as now seems possible, make widely known the fact that it has taken the new departure which I suggest, the fortune of the paper ought to be ensured. I make the proprietor a present of the suggestion.

I am, Sir, yours truly,
Cavendish Square.
April 5th, 1906.
HENRY SEWILL.

THE TREATMENT OF CANCER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In "A Clinical Lecture on Cancer of the Uterus," by Dr. William Alexander, in THE MEDICAL PRESS AND CIRCULAR of April 4th, 1906, I notice that he recommends the administration of dilute hydrochloric acid in maximum doses. "We may suppose" he states, "a tendency to alkalinity in the tissues. . . . Owing to this change in chemical reaction of the tissues, a rapid proliferation of epithelium that was hitherto kept within bounds by a more acid state of the medium in which the epithelial cells now lie, now takes place, and is promoted by the change from acid to alkaline surroundings, as Professor Moore has shown from his experiments on the eggs of the sea-urchin. Therefore if we can render the tissues of a cancer patient more acid, we can retard the growth of cancer. . . ."

It would be interesting to know how Dr. Alexander is able to reconcile his recommendation with the full views expressed by himself and others with Professor Moore(a), in relation to the growth of the eggs of the sea urchin, in a paper read before the Royal Society, viz., "It is only a trace of additional alkali which causes the increased growth, more than a trace stops it entirely."

I am, sir, yours truly,
J. A. SHAW-MACKENZIE, M.D.LOND.
London, April 6th, 1906.

(a) "On the Absence or Marked Diminution of Free Hydrochloric Acid in the Gastric Contents in Malignant Disease of Organs other than the Stomach." By Benjamin Moore, M.A., D.Sc.; in collaboration with Messrs. W. Alexander, M.D., F.R.C.S.; R. E. Kelly, M.B., B.Sc.; and H. E. Roaf, M.B.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

ULSTER HOSPITAL FOR CHILDREN AND WOMEN.—The annual meeting of this hospital was held last week, Mr. Edwin Hughes, J.P., in the chair. The medical staff reported increasing work in all departments. There were 216 children and 81 women admitted to the wards, and 126 operations in the former and 58 in the latter. In the extern department, 2,386 children and 623 women were seen; 172 maternity cases were attended by the hospital nurses. The total number of visits paid by or to patients was 9,493. Drs. Leslie, Williamson, and Howard Stevenson, with Dr. Cecil Shaw, the hon. sec. of the staff, were appointed representatives of the medical staff on the Board of Management. In the report of the Board of Management reference was made to the want of a new hospital to meet the needs of this large and growing working-class district. The present hospital is an old dwelling-house converted to hospital purposes,

but can never be thoroughly satisfactory, and in any case is far too small for the work that is being done.

ROYAL VICTORIA HOSPITAL.—At the first meeting of the new committee for the year, held last week, the following were elected representatives of the Medical Staff on the Board of Management:—Sir Wm. Whitla, Professor Byers, Drs. Mitchell, Calwell, and McKisack.

THE HEALTH OF BELFAST.—Serious attention is being called in the daily press to the question of the health of the city. It appears that for the last eight weeks the death-rate has varied from 20 to 27, being from 4.5 to 10.8 in excess of the average of the great towns. The chairman of the Public Health Committee has endeavoured to reassure the public by pointing out that fluctuations are to be expected, and compares Belfast, which has about 350,000 inhabitants, with Ballymena, which has 11,000, and Lurgan, which has 13,000! It would be hard to find a better instance of the misuse of statistics, for in small towns like these a very small number of cases will affect the rate in a way that is impossible in a large city. During the previous four weeks there had been notified in Belfast 269 cases of zymotic disease, including 115 scarlatina, 57 typhoid, 37 each simple continued fever and erysipelas, 17 diphtheria, 3 puerperal, 2 membranous croup, and 1 typhus. During the same period there were 62 deaths from zymotic diseases and 224 from respiratory affections. The authorities are evidently becoming a little alarmed at the attention that is being called to the state of the public health, and at their last meeting the Committee had a serious discussion on the high death-rate. It appears that in the week ending March 31st, there were no less than 21 deaths from whooping-cough, and 18 from pneumonia. The question of making whooping-cough a notifiable disease was discussed, but for the present at least this step will not be taken.

OBITUARY.

JAMES WILSON, M.A., M.D.

ON March 30th, Dr. James Wilson, M.A., of Govan, died at his residence of apoplexy, at the age of fifty-three. Dr. Wilson was born in Glasgow. He had a distinguished career at Glasgow University, where he graduated M.A., with honours, winning among other distinctions the Blackstone medal for Latin. He practised in Govan for over twenty years, and for several years served on the Town Council (then the Police Commission Board), and also on the County Council.

CHARLES QUINTON, M.R.C.S., L.S.A.

We regret to record the death of Mr. Charles Quinton, M.R.C.S., L.S.A., of Sandy, at the age of seventy-six. He was a member of an old Staffordshire family. The third son of the late Charles Quinton, of Newbolds, Wolverhampton, he was born on January 9, 1830, and received his professional training at the Sydenham College Medical School, Birmingham, where he had a distinguished career, being awarded two first prizes for medicine, anatomy, physiology, midwifery and general proficiency, and was appointed prosector of anatomy at the College. He obtained his M.R.C.S. diploma in 1854 and that of L.S.A. in 1867. His first charge after leaving college was at Tettenhall, Staffordshire, where he carried on a successful practice for some years. Removing to Grosmont, Yorkshire, he remained there for twenty-nine years, holding the appointments of district medical officer of health to the Whitby Union and public vaccinator and surgeon to the Grosmont Ironworks. His large private practice at length proving too much for his strength, he relinquished it and came to Sandy in 1895, and practised there until within a short time of his death.

JAMES PARSONS THORNTON, M.D.DUR., L.S.A. LOND., OF SOUTHPORT.

The death occurred at his residence, Lord Street,

Southport, on Saturday evening of Mr. James Parsons Thornton, at the age of fifty-eight. Deceased was the son of the Rev. John Thornton, Stockport, and was M.D. of Durham (1889), and L.S.A. of London (1872). He commenced practice at Southport, and continued it up to his death, with the exception of a brief period of a few years ago, during which he resided at Torquay.

REVIEWS OF BOOKS.

ESSENTIALS OF HUMAN PHYSIOLOGY FOR VETERINARY STUDENTS. (a)

THE author's aim, as stated in the preface, is to put before medical students as succinctly as possible the facts of human physiology, essential to the study of medicine and surgery, and in this he has succeeded. Pascal has said that "the last thing we find in making a book is to know what we must put first," and writers of physiological text-books seem to have experienced the truth of this saying in full. Dr. Paton's method of beginning and pursuing his subject differs in some respects from most others. The book is primarily divided into three parts. Part I. treats of the Tissues; Part II., of the Nutrition of the Tissues; Part III., of Reproduction. There are no chapters; each part is divided into sections, of which there are twelve in all.

In dealing with the Tissues in Part I., they are somewhat artificially divided into "vegetative" and "master" tissues. The account of the former (Epithelium and the connective tissues) is mainly confined to structure, with short references to chemical composition and function. A useful feature, considering the aim of the work, is the advantage taken in this and other sections of every legitimate occasion to introduce minor doses of physiological chemistry, where connection can be established with the matter in hand. In a few instances exception might perhaps be taken to the terminology, as, for instance, "proteates," applied to acid-albumin and alkali-albuminate, also "formed" material applied to ground substance in connective tissue.

Under the head of "Master Tissues" is given the structure, chemistry and physiology of muscle and nerve. In connection with the latter and under the head of "Sensation," the author introduces the physiology of vision, hearing, smell and other special senses. Following the special senses comes the chief account of the nervous system, both sympathetic and cerebrospinal. That of the former, though much compressed, is distinctly good.

In Part II., the section on Lymph, considering its undoubted clinical importance, might be somewhat enlarged. That devoted to the circulation conveys a useful and judicious amount of information clearly imparted. The reader will probably abandon the attempt to reconcile in all cases the subject treated of, with the heading or sub-heading to which it is allocated. Fortunately this can be done without impairing the usefulness of this part of the book. The physiology of respiration and voice production are included in a section which treats of the "supply of nourishing material to the blood and lymph, and elimination of waste material from them." It is not stated whether the latter function comes under the head of elimination or supply.

The remaining sections of this part are devoted to "food and its digestion," "internal secretions," "excretion from the body." They are relatively short, that on digestion proper being perhaps the most condensed of all.

Part III. comprises eight pages devoted to the structure of the organs of reproduction, and to a short account of development. An appendix of four pages, in which are given some elementary but useful facts of organic chemistry, concludes the work.

(a) "Essentials of Human Physiology for Veterinary Students." By D. Noel Paton, M.D., &c. Edinburgh and London: William Green and Sons.

The book as a whole is pleasing. It is attractively got up, its instruction, so far as it goes, is sound. Its teaching is emphatic, and the selection of matter is judicious. More, perhaps, might have been done to furnish reasons for the statements given, and thus early awaken the student's attention to the all-important fact. That knowledge of function, or derangement of function, is seldom absolute, but has to be deduced from groups of opposing data, which in many cases almost counterbalance each other.

By the addition of four and a half pages, chiefly on muscular movements in the horse, and four on digestion in herbivorous animals, with the omission of ten pages on the senses, four on the nervous system, three on the circulation, four on respiratory movements, and three on articles of diet, the second edition of the work has been neatly transformed into the "Essentials of Physiology for Veterinary Students." *

THE STUDY OF DISEASE. (a)

THAT this comparatively young society is doing good work, a cursory perusal of the reports before us serve at once to show. The Wightman lecture on "Some Neuroses of Early Life" is most interesting, as is also the discussion on the question of sudden death occurring in children. Mr. Tubby contributes a comprehensive paper on the question viewed from its surgical aspect, while the editor himself surveys it from the more strictly medical side. The value of such a discussion cannot be over-estimated, and we regard its record as one of the most important sections of these reports. A paper of much interest is that on appendicitis, contributed by Mr. H. A. Whitelocke. Dr. Grünbaum's paper on Congenital Tropic Edema contains an account of three cases of this curious and somewhat rare form of Edema. Such are a few of the excellent things contained within this volume which, by the way, is well illustrated. Altogether the society must be congratulated on being able to produce such a praiseworthy record of work accomplished by its members. Under the editorship of Dr. Carpenter the volume is assured of every care in its production, and even general practitioners will find its perusal helpful and instructive. To the specialist this volume of reports is an absolute necessity to enable him to keep pace with the progress made in the study of pædiatrics in this country.

HEBBLETHWAITE'S GENERAL PRACTICE. (b)

Who has not derived help from listening to the account given by an experienced practitioner of the interesting cases he has met with in practice? The writer of this little book gives his readers the benefit of his own experiences in a chatty style, free from anything like verbosity or presumptiveness. His remarks and notes cover the entire range of general practice. He has a good deal to say on the subject of peritoneal catastrophes and his words are very much to the point. His treatment of ulcer of the stomach is based upon practical experience, and he does not believe in withholding mouth feeding in every case. "It is somewhat surprising how the regulation of the quantity of food and the times of feeding is successful in curing the symptoms." He believes that urine-testing is very much neglected in general practice, and gives a brief account of his own method together with the conclusions to be derived from results obtained. The notes on fractures and their treatment will be specially useful to the newly-fledged practitioner, as will also the advice given on infant feeding. Dr. Hebblethwaite speaks very temperately regarding the use of infants' "foods," but on the whole does not seem to encourage their adoption generally in practice. The obstetrical notes are good as far as they go, but in another edition we would advise the author to extend them, as this is

the very subject on which young practitioners require most help and guidance. The little book contains a number of hints and ideas of considerable value, and we have no doubt that by increasing the number of topics dealt with it will become a general favourite with those who are starting upon their life's work.

LITERARY NOTES.

DR. J. W. BALLANTYNE, of Edinburgh, who is but 44 years of age, has, says *Medical Notes and Queries*, written nine volumes on Obstetrics, Gynæcology, and Antenatal Pathology; two volumes of a Journal of Antenatal Pathology; sixteen articles in medical encyclopædias and dictionaries; 129 articles in medical journals; 101 shorter contributions to medical journals, and numerous annotations, abstracts, &c.

WE understand that the fourth edition of the manual on "Heart Disease," by Sir Wm. Broadbent, Bart., the third edition of which has been out of print for some time, is now free of the press, and will be ready in a few days. Sir William has been assisted in the revision by his son, Dr. John Broadbent, and chapters have been added on the pulse, disease of the coronary arteries, bradycardia, and atheroma of the arteries; and important additions have been made to the chapters on "angina pectoris" and functional affections of the heart.

"THE BLOODLESS PHLEBOTOMIST" is the extraordinary title chosen for a medical journal recently started in New York. This title, however, is the only part of the programme to which exception may be taken on conservative grounds, supposing the April number to be a fair specimen of future issues. In this we find some interesting articles by well-known American writers, among which we may cite "Proprietary Remedies from the Physician's Standpoint," by W. J. Robinson, Ph.D., M.D.; "The Lesson of the Yellow Fever Epidemic," by Daniel Lewis, M.D., LL.D.; and "Delirium Tremens," by T. D. Crothers, M.D.

DR. LOUIS SEAMAN, an American surgeon, who volunteered his services to the Japanese in the late war, has contributed an interesting account of the thoroughness and skill of the Japanese medical department. In the Japanese archipelago, he says, no fewer than twelve sets of main hospitals were organised, to each of which from one to five branch hospitals were attached. The 25,000 beds which these originally provided were increased rapidly in number as the campaign was prosecuted. In the field every practical precaution against disease was taken. All milk used in the army was sterilised, all the water used was boiled. Every bandage was disinfected. Chemists went ahead of the army with the vanguard, and after testing the water of every well, labelled it drinkable or undrinkable. The surgical and medical treatment was scarcely less remarkable than was the sanitary system. Only one and a half per cent. of the soldiers died of gun-shot wounds, although twenty-four per cent. were wounded.

Glasgow Royal Infirmary.

DRS. HENDERSON and McNair have been promoted from the position of extra-dispensary physicians to dispensary physicians at the Glasgow Royal Infirmary. And Drs. Key, Faulds, and McEwen have been promoted to be dispensary surgeons. The posts thus rendered vacant will be duly advertised.

DR. EDWARD MAGENNIS has been selected as a candidate for the vacancy on the Senate of the Royal University of Ireland. Dr. Campbell, of Belfast, has also come forward as a candidate. The vacancy was caused by the resignation of his Honour Judge Shaw, who was a representative of the Convocation of the University of the Senate.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons of England.—Important Awards.

A QUARTERLY meeting of the Council was held at the College on Thursday, the 5th instant, Mr. John Tweedy, President, in the chair.

Walker Prize for Cancer Research.—The Walker prize of £100, founded by the late Mr. Charles C. Walker, of Lilleshall Old Hall, Newport, Salop, to encourage investigation into the pathology and therapeutics of cancer, was awarded to Professor Carl O. Jensen, of Copenhagen. The Committee appointed to advise the Council of the College in reference to the award of the prize reported as follows:—After receiving valuable advice and assistance from eminent American, Belgian, Danish, French, German, Italian, Swedish, Swiss, and British surgeons and pathologists, regarding the work carried out in their respective countries, and after making careful examination of papers dealing with the pathology and treatment of cancer published in various languages during the last five years, it became evident to the Committee that in any report to be presented to the Council much important work could not be considered, because it had not been done within the prescribed time limit; it had no direct bearing on the treatment of cancer; it was still being pursued and the prize could scarcely be awarded to it at this stage of its progress, although it will fall under the consideration of the Council when the Walker Prize is next awarded.

The Committee were of opinion that Professor Jensen should receive the prize on this occasion. His work is described in a letter from Professor Salomonsen of the State Serum Institute of Copenhagen, and the Committee felt that they could not do better than cite this.

The inoculation of cancer from animal to animal had been made in comparatively few cases, and therefore afforded no decisive material for the study of cancer. Professor Jensen first succeeded in discovering a tumour in the mouse, which made the experimental investigation of cancer on a large scale possible.

Professor Jensen first carried out a large series of inoculations through thirty-five generations, comprehending about 1,000 mice, and thus gave the impulse to certain experimental investigations which are now carried out in many laboratories in different parts of the world. He thus made it possible to investigate, and was himself the first person to investigate systematically, the effect of different factors (heat, light, chemical agents, radium, etc.) on these cancer cells. He has further demonstrated the possibility of producing an anti-cancer serum for mice by the injection of the crushed tumour into rabbits. The serum of rabbits which have been thus prepared has been injected into mice suffering from cancer, with the result that the cancer-tumours in many of them have disappeared absolutely and permanently.

In proposing Professor Jensen to the Council as a fitting recipient of the Walker prize, the Committee have been influenced by the not merely actual work which he has himself done in investigating the nature of cancer, and the effect of treatment upon it, but also by the extent to which he has opened up a field of research to those engaged in the study of cancer on certain lines, enabling them to carry out their investigations over longer periods of time and under better and more determined conditions than have up to the present time been possible.

Jacksonian Prize.—The Jacksonian prize for 1905 was awarded to Reginald Cheyne Elmslie, M.S., F.R.C.S., for his essay on "The Pathology and Treatment of Deformities of the Long Bones due to Disease occurring during and after Adolescence." The prize-subject for the year 1907 will be "The Operative

Surgery of the Heart and Lungs, including the Pericardium and the Pleura." The John Tomes and Cartwright prizes were not awarded. The following was selected as the subject for essays to be submitted in competition for the Cartwright prize for the period 1906-1910—"Prevention of Dental Caries."

First Begley Student Appointed.—Mr. Walter Burford Johnson, of St. Thomas' Hospital, was appointed the first Begley student in accordance with the report from the Examiners in Anatomy and Physiology at the recent Second Examination of the Conjoint Board.

Elections.—Dr. Lucas Championniere, Surgeon to the Hotel Dieu, Paris, was elected an Honorary Fellow of the College. Surgeon-Gen. Arthur Mudge Branfoot, C.I.E., President of the Medical Board, India Office, and Mr. Herbert M. Ellis, R.N., Director-General of the Medical Department of the Royal Navy, were elected Fellows of the College under the rule relating to members of twenty years' standing.

Honorary Medal.—The honorary medal of the College was awarded to Lieut.-Col. Sir Richard Havelock Charles, K.C.V.O., I.M.S., in appreciative recognition of his gift of anthropological specimens, an addition to the Museum of special value and importance, not only on account of the number and variety of the specimens presented, but also on account of the authentic particulars attached to them.

Medico-Psychological Association of Great Britain and Ireland.

THE next meeting of the Northern and Midland Division will be held, through the courtesy of Dr. Macphail, at Derby Borough Asylum, on Thursday, April 19th, at 2.30 p.m. Dr. Macphail kindly invites members to lunch on the day of the meeting, and it is proposed that members should dine together afterwards at the Midland Hotel, Derby, should a sufficient number intimate their intention of being present to Mr. Bedford Pierce, hon. sec. of the Division, The Retreat, York. The election of several new members will be proposed at this meeting, and Drs. Nathan Raw, John Richards, and Wm. Harding will read papers.

The Brighton's Council's Consumption Scheme.

A declaration of trust is being arranged so that the Brighton Corporation may administer the income of £20,000, part of the Hedgcock Bequest, for the treatment of consumptive patients in the town during the next ten years. The following are the principal heads of the scheme which the Sanitary Committee recommend should be embodied in the declaration of trust:—

1. The Corporation shall provide at the Sanatorium suitable accommodation, nursing and medical attendance, for the treatment of resident consumptive patients admitted under the provisions of this scheme.

2. The income received from the investments of the sum of £20,000, part of the Hedgcock Bequest allotted by the Council for this purpose, shall be placed to a separate account to be termed the "Hedgcock Bequest (Consumption) Account."

3. The income of the said fund shall be applied in payment towards the general expenses of the Borough Sanatorium of the sum of £1 per week in respect of each consumptive patient admitted to the Sanatorium for treatment in pursuance of this scheme, such weekly sum representing the cost of maintenance and treatment of each patient.

4. The class of patient to be admitted for treatment, and the duration of treatment of each patient, shall be decided by the Sanitary Committee of the Council on the advice of the Medical Officer of Health, subject to the following conditions:—(a) That each patient

has been resident in the county borough of Brighton for not less than two years immediately prior to the proposed admission, except in cases where, for special reasons, the Sanitary Committee decide by resolution to dispense with this condition. (b) That the patient is unable to pay for treatment, and is a fit person to receive the benefits of the charity.

Royal College of Surgeons, Ireland.

THE following is the prize list for the winter session, 1905-1906:—

Descriptive Anatomy.—Junior—W. A. Swan, first prize (£2) and medal; A. A. Pellissier, second prize (£1) and certificate; Senior—G. C. Sneyd, first prize (£2) and medal; I. Scher, second prize (£1) and certificate.

Practical Anatomy.—First Year—H. D. Gasteen, first prize (£2) and medal; H. G. P. Armitage, second prize (£1) and certificate. Second Year—H. J. Hedley, first prize (£2) and medal; Miss I. M. Clarke, second prize (£2) and certificate.

Practise of Medicine.—H. W. White, first prize (£2) and medal; D. Adams, second prize (£1) and certificate.

Surgery.—H. W. White, first prize (£2) and medal; T. Sheehy, second prize (£1) and certificate.

Midwifery.—H. C. Carden, first prize (£2) and medal; W. E. M. Hitchins and T. Sheehy (equal), second prize (£1) and certificate.

Physiology.—H. J. Hedley, first prize (£2) and medal; J. Menton, second prize (£1) and certificate.

Chemistry.—J. J. Lyons, first prize (£2) and medal; R. White, second prize (£1) and certificate.

Pathology.—H. W. Kay, first prize (£2) and medal; G. S. Lewis, second prize (£1) and certificate.

Physics.—R. White, first prize (£2) and medal; R. H. Weir, second prize (£1) and certificate.

The Summer Session commenced on Monday, April 2nd.

Hospital Saturday Fund.

At the annual general meeting of the Hospital Saturday Fund Association held on Saturday last, Sir Savile B. Crossley, in the chair, the report of the council showed that the receipts from the workshops and business houses had reached £25,930, as compared with £24,344 in 1904, an increase of £1,586. The total was the highest recorded in the history of the movement. The expenses of management amounted to 9.49 per cent. of the gross receipts. The Board of Delegates in January last distributed the sum of £23,631 among 202 hospitals, dispensaries and convalescent homes, &c., this amount being £1,766 more than in any former year. The council noted that the National Association for the Establishment and Maintenance of Sanatoria for workers suffering from tuberculosis was making satisfactory progress; and the Fund has voted the sum of £500 towards its work. The pressing need for increased accommodation for patients of this class is generally admitted, and it is hoped that the Association will be in a position to receive patients by the end of the present year, when the new buildings are completed at Benenden, in Kent.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Accident and Life Assurance Society was held at 429, Strand, London, W.C., on the 30th ult. There were present Dr. De Havilland Hall, in the chair, Dr. Mayn Greenwood, Dr. F. S. Palmer, Mr. F. S. Edwards, Mr. Wm. Thomas (Birmingham), and Dr. J. B. Ball.

The accounts presented showed that the business of the Society for this year had so far been exceptionally good. During the first quarter of the year the sickness claims received are usually largely in excess of the average, but so far is this from being the case in 1906, that in the months of January and February there was a margin in favour of the Society, and in March the claims received, though numerous, are of a slight nature, and causing a very moderate draft on the funds of the Society, which now amount to more than £200,000. Prospectuses and all particulars on

application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

A Physician's Salary in Parliament.

IN the House of Commons last week Mr. Gilhooly asked the Secretary to the Treasury whether it is proposed to fix the salary of the acting physician to the Youghal Auxiliary Lunatic Asylum at £100 per annum, for a limited time; and whether the Board of Governors are to have any control in determining the amount of this salary.

Mr. Bryce replied that the power of fixing the salary of the visiting physician to this institution is vested by statute in the Committee of Management, subject to the concurrence of the Lord Lieutenant. The Committee have fixed the salary at £100 per annum, with the proviso that the physician may, after eight years' satisfactory service, receive an increase not exceeding £25 per annum. The Lord Lieutenant, however, has not yet signified his concurrence, owing to the fact that certain temporary difficulties have arisen in framing regulations for the management of the institution.

University of Aberdeen.

At the Graduation ceremony on Thursday last, April 5th, the following degrees were conferred:—

DOCTOR OF MEDICINE (M.D.).

** Cruickshank, Lewis Davie, M.B., Ch.B., Darlaston, Staffs.

**Galloway, John Charles, M.A., M.B., Ch.B., Banff. Holt, Thomas, M.B., C.M., Burnley.

Johnston, George Hall, M.B., C.M., Wath-upon-Dearne.

Mackenzie, Dudley Macdonald, M.B., Ch.B., Ealing, W.

Mitchell, Robert, M.B., C.M., Hooton Pagnell. ***Pearse, Wilfrid William, M.B., C.M., Acting.

Medical Officer of Health, Hong-Kong.
Rose, Alexander, M.B., C.M., South Norwood, S.E.
Sutherland, Arthur Leslie, M.A., M.B., Ch.B., Darwin.

**** "Highest Honours" for Thesis.

*** "Honours" for Thesis.

BACHELOR OF MEDICINE (M.B.) AND BACHELOR OF SURGERY (Ch.B.).

With First Class Honours.

*Gill, John Frederic, B.Sc., Ackworth, Pontefract.

**McKerrow, William A. H., Workington.

* Passed Final Examination with "Distinction."

** Passed Final Examination with "Much Distinction."

Trinity College, Dublin.—Conjoint Examinations in Ireland.

CANDIDATES have passed the First Professional (March and April, 1906) Examination as undernoted:—
R. White (with honours), S. Campbell, R. Charles, D. F. Curren, J. Donegan, J. Donoghue, J. W. Flood, F. R. Jones, L. C. King, J. Mitchell, T. Murray, J. T. MacDonnell, F. McDonnell, M. O'Brien, P. O'Farrell, W. R. O'Keefe, and R. A. Wright.

Second Professional Examination.—Messrs. G. C. Sneyd and J. T. McKee (with honours), E. M. Donovan, D. J. Lyne, J. O'L. Murray, J. M. Smythe.

At Hilary Term, 1906, the following candidates passed the final examination in Medicine Part II.:

Surgery.—John D. Sands (passed on high marks), Basil G. Brooke, Robert B. Jackson, Ralph S. Oldham, Samuel G. S. Haughton, Alfred G. Alexander, Hercules J. Knox, Gustav W. Thompson.

PROFESSOR KOCH left Berlin on Saturday for Naples, whence he sails for Tanga on the 16th inst. From Tanga he will set out for the interior of Africa at the head of a German Imperial expedition to investigate "sleeping sickness."

THE last meeting of the Society for the Study of Inebriety was held on Tuesday, April 10th, 1906, in the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W., when Dr. Harry Campbell opened a discussion on "The Alcoholic Craving," which will be found in another column under "Original Papers."

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Tuberculous Nephritis and Cystitis in the Female.—Mirabeau (*Monats. f. Geb. u. Gyn.*, February, 1906) concludes after several years' investigation: (1) That tuberculosis of the bladder in women is, without exception, a secondary process, descending from the kidney, and stands in no direct relation to genital tuberculosis; (2) in at least 50 per cent. of all cases, renal tuberculosis is unilateral; (3) by means of the cystoscope, and ureteral catheterism, diagnosis may be made absolute; (4) detection by palpation of a thickened ureter is practically sufficient, and can be detected by practitioners not specially experts in renal and vesical surgery; (5) in unilateral renal disease descending to the bladder, the full functional activity of the healthy kidney can usually be determined by clinical observation and by chemical and microscopical examination of the urine isolated by ureteral catheterism and the segregator, if not, examination of the kidney itself may be necessary; (6) early removal of the tuberculous kidney is sometimes the best treatment. Mirabeau performed nephrectomy on a patient suffering from unilateral renal tuberculosis in the fifth month of pregnancy. The patient was delivered at term of a healthy child, and was in very good condition two and a half years later.

Appendicitis Complicating Pregnancy and Parturition.—E. Davis (*American Journal of Obstetrics*, March, 1906) cites cases of appendicitis of an acute and chronic nature operated on during pregnancy with normal convalescence and delivery at term. From his experience and the literature of the subject, he concludes appendicitis is not predisposed to by pregnancy, and if it occurs it may happen at any time during pregnancy, and may be primary or secondary. In mild cases the vomiting which accompanies the attack may be mistaken for the vomiting of pregnancy, and in cases complicating early pregnancy and the puerperal period pain is apt to be referred to the region of the liver, and even the left side of the abdomen, rather than to the affected region. Appendicitis during pregnancy runs a rapid course, and suppuration in a majority of cases will develop. Where pus is formed it should be evacuated at the earliest possible moment, and it should be remembered that the uterus and tube usually form one of the walls of the abscess. In evacuating pus, tissues should be disturbed as little as possible to avoid abortion or premature labour, and to prevent pus becoming disseminated throughout the abdomen. The occurrence of premature labour is unfortunate in these cases, and always adds greatly to the gravity of the situation owing to the breaking up of the abscess wall. Davis, in conclusion, draws attention to the fact that adhesions following appendicitis may bring discomfort and danger to a patient who becomes pregnant after she has recovered from disease of the appendix, and urges, in view of the serious consequences which follow appendicitis in pregnant women, the appendix be removed as soon as inflammation is diagnosed; remembering the impossibility of differentiating between inflammation of the right tube and ovary and of the appendix, operation should be done without waiting to make a positive diagnosis. F.

Acute Cholecystitis in the Puerperium.—Vineberg (*Amer. Med.*, March, 1906) says that, taking into consideration the frequency with which women suffer from gall-stones, and bearing in mind the statement made by reliable authorities that pregnancy and labour favour the occurrence of biliary colic, acute cholecystitis in the puerperium ought to be of more frequent occurrence than the literature would seem to warrant. It is probable that the disease is often

overlooked, or is mistaken for puerperal sepsis. The author cites two cases with symptoms of acute abdominal inflammation, occurring on the ninth and tenth days after delivery respectively, ascribed to sepsis by the attending physicians, but at the operation the diagnosis of acute cholecystitis was confirmed. Christiani also reports two cases and points out the importance of bearing this complication in mind with regard to differential diagnosis, as the danger to which, where the condition is not made out, the woman is exposed, on the one hand from useless, if not injurious, intra-uterine interference, on the other from the possible empyæma of the gall bladder not being dealt with by timely operation, is very considerable. F.

Enucleation of Fibro-myoma of Uterus during Pregnancy (*Brit. Med. Journ.*, March 10th, 1906).—J. Stewart, Leeds, records a case under this heading pointing out how infrequently fibroids of the uterus require enucleation during the pregnant state and mentions that Schroeder was the originator of the idea. Dr. Stewart was sent for at night to see a patient between five and six months pregnant, complaining of severe pain in the back, constant in character with exacerbations. A vaginal examination showed the cervix to be normal and as there was no hæmorrhage, he gave the patient an injection of morphine and diagnosed a threatened miscarriage. The following morning, upon making a thorough examination, revealed a tumour about the size of the fist, hard, smooth, dull on percussion, and tender on handling, tympanitic all round and a well-marked dulness between it and the uterus. Nothing distinctive was made out by vaginal examination. The patient stated that she became pregnant five months previously and had enjoyed good health till three days before, when she was seized with violent pain in the lower part of back, which remained constant and was unassociated with hæmorrhage, vomiting ensued, caused by the ingestion of food. The temperature at the time of examination was 101° F., and the pulse 110. A fortnight before she had noticed a movable lump in her left side. After this examination the diagnosis of ovarian cyst, probably dermoid, which had undergone axial rotation, was made. Mr. Moynihan saw the case in consultation and agreed with this view. The following day the abdomen was opened and, a sessile tumour was found attached to the left of the fundus uteri. There were no adhesions and no discolouration of the peritoneum covering the tumour. The uterus was rotated so that the tumour appeared in the incision. A third of the tumour was found embedded in the wall of the uterus. A circular incision was made and the fibroid shelled out. Hæmorrhage, was severe and difficult to control, but was finally checked by pressure and drawing the sides of the uterine wound together with Pagenstecher's thread and overlapping stitches. On section the tumour showed no signs of hæmorrhage into its substance nor beneath its capsule. Dr. Stewart believes the pain was due to the malignant influence all fibroids have upon the pregnant state—a tendency to produce abortion or miscarriage. The patient was confined at full term of a living male. H.

Lumbar Puncture in Puerperal Eclampsia (*Brit. Med. Journ.*, March 24th, 1906).—Proud, Maryport, while considering the pathology of infantile convulsions and their recent treatment by lumbar puncture, was led to speculate on its value in the analogous conditions of some parturient adults. Eclampsia, he considers, arises in cases with marked symptoms of renal disturbance, but whether the convulsions are due to toxæmia or to pressure on the cerebral centres has

not been established by pathologists. In two cases of eclampsia he carried out lumbar puncture with gratifying results. In the first case the convulsions came on after labour, and were very numerous and severe. Chloral, salt solution, croton oil, and packs were tried without avail. The coma was deep and the pulse irregular and feeble. Puncture was made in the third lumbar interspace and a rapid dropping of fluid followed for some minutes. The fits ceased and the patient gradually came round. The second case was one in which a primipara was affected. She had had several fits during eight hours before being seen by the doctor. As the head of the child was on the perinæum, forceps were applied and the child delivered. After this the patient remained deeply comatose with stertor and cyanosis. An hour later the pulse was scarcely perceptible. Hot packs, croton oil, and pilocarpin, &c., were tried. Puncture was made in the third lumbar interspace, when there was a quick gush of fluid, evidently under pressure, about half an ounce in amount. The patient becoming unruly, the needle was withdrawn; her breathing was now regular, and no more fits occurred. She gradually recovered consciousness and convalesced normally.

H.

Vaporisation of the Uterus.—Karl Baisch (*Zentralblatt f. Gynäk.*, January 6th, 1906) says it is not to be denied that curettage fails in a large number of cases, especially in the forms of metro-endometritis observed about the menopause. Among the material of the Frauenklinik in Tübingen, only one-third of the patients between 40 and 50 years of age have been cured by curettage. It is among these cases, which frequently call for total extirpation, that vaporisation proves itself of benefit. As the result of the microscopical examination of a very large number of uteri in which vaporisation had been employed, the author declares that the temperature of the steam and the length of time of its application have very much less influence on the effect than is generally supposed. The inner surface of the uterus is always scalded to a depth of about 2 mm., and this burnt stratum protects the deeper layers from further injury. Subjacent to the burnt stratum, one can recognise macroscopically an intensely hæmorrhagic zone, which is also about 2 mm. thick. According to the histological nature of the burnt tissue the therapeutic effect varies. When the steam works on a fungous hypertrophic mucosa the glands are preserved to a considerable degree, and after a short time the former condition returns. If the mucous membrane is thin and atrophied it will be completely destroyed and the uterus obliterated. Thus the different opinions of authors are to be explained. Now as one does not know the thickness of the mucous membrane before vaporisation, the latter is contra-indicated during the reproductive period of the woman's life. A reliable result is obtained when curettage precedes the vaporisation either at the same sitting, when, owing to the painfulness of the procedure an anæsthetic must be given, or, better, five to seven days after the curettage, when with the regeneration of the mucous membrane the vaporisation causes no pain and can be done without anæsthesia, and there is no bleeding to hinder the deep action of the steam. The combination of curettage and vaporisation is the better method for production of the menopause. A graduation of the effect so that after the vaporisation the periods become weaker and more regular is never to be obtained with certainty. Without the preceding curettage success must be completely left to chance. The vaporisation is only to be used in smooth-walled, regularly built, uterine cavities. Myomata contra-indicate it. It is usually not only unsuccessful in their presence, but also very dangerous owing to the possibility of gangrene. Every infection, whether septic or gonorrhœal, of the uterus or of its adnexa, must be considered a strict contra-indication to vaporisation. There remains, therefore, for the method only the simple uncomplicated cases of premenstrual hæmorrhage for which it gives, when com-

bined with curettage, a most satisfying result—and is thus a rich addition to conservative therapy. G.

The Prevention of Fever in the Puerperium.—Zweifel (*Zentralbl. f. Gyn.*, January, 1906) again proposes that the blood clots which regularly collect in the posterior fornix *post-partum*, should be removed because they can become a breeding ground for pathogenic micro-organisms, and from the extension of the latter to the uterus fever arises. A speculum is introduced into the vagina during the first visit to the lying-in woman, that is, several hours *post-partum*, and the clots removed with a dry sterile sponge or forceps. It is a quite painless and harmless procedure, and gives better results than douching. The best method of all is when the woman is able to press out the clot herself. The results of this treatment in his Klinik are that there is a large decrease in the number of septic cases, because spontaneous infection is less likely to occur, and that the lochial discharge is only very lightly bloody for a few days. Rubber gloves must always be worn, and as few internal examinations as possible should be made before the delivery of the child. G.

The Technique of the Cæsarean Section.—Olshausen (*Zentralbl. f. Gynäk.*, January 6th, 1906) contributes, among others, the following observations on this subject based on his experience of 118 Cæsarean sections performed in his Klinik. The operation was performed for contracted pelvis in 91 cases, and the remaining 27 were for eclampsia, myomata, carcinoma, vaginal fixation, nephritis, vitium cordis, and stenosis due to cicatricial tissue in the cervix or vagina. As regards the technique, the abdominal incision must extend from a good distance above the umbilicus to about 8 cm. or more from the symphysis pubis, so that the uterus can be raised outside the abdominal wall. A sponge is then put behind it, and the wall drawn temporarily together with two forceps. The uterine incision must avoid the placenta. The position of the latter is discovered when one observes the injection of the uterine wall, which is most marked over the placental site. By this means, the author was uncertain of the position in only two of his cases. If the anterior wall is much more prominent than the posterior, the placenta is nearly certain to be on the former. The same does not stand for the normally more prominent posterior wall. One can open the posterior wall just as well as the anterior. There is no longer any need to fear hæmorrhage if a large dose of ergotinine is hypodermically injected about twenty minutes before the operation. The uterine incision must be made in the middle line. When this is done and the placenta is avoided the hæmorrhage is never dangerous. Compression of the cervix is superfluous; in fact, it should be avoided because more severe hæmorrhage takes place when it is removed. The sutures are of catgut, and are inserted so that as much muscle as possible without peritoneum or decidua is seized. The interrupted sutures are then carefully tied, and the peritoneum is closed with a continuous suture above them. In seven women the operation was performed twice, in two three times, and in three four times. All these twelve recovered. Among the 91 operations for contracted pelvis, nine died. The author operated personally on 65 cases with three deaths, his assistants on 26 cases with six deaths. G.

NOTE.—A summary will appear each week in the following sequence:—

- (1) "Recent Medical Literature."
- (2) "Recent Surgical Literature."
- (3) "Recent Gynecological and Obstetrical Literature."
- (4) "The Recent Literature of Physiology, and Pathology."

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

CLAPHAM PRACTITIONER.—We quite agree with you that in admitting a notice of a "beauty" show to its advertisement columns a certain esteemed and distinguished medical contemporary is establishing a somewhat doubtful precedent.

SIR JOHN B.—A considerable sum of money is needed to found the proposed Institute of medical sciences in connection with the University of London. The scheme promises well—in fact more than any yet advanced—as regards unification and sound organisation of medical teaching in the metropolis. We shall be pleased to give you the names of persons authorised to receive subscriptions to this most excellent educational project.

ARRIVAL AND DEPARTURE (BUT NOT BY COOK'S EXCURSION).

By "motor" and "steamboat" and "train"
We leave home, and we come back again.
But to enter this world, and leave it, we're bound
To come in by the "Tube" and depart "Underground,"
Except for the few who are otherwise fated
To be drowned, blown to bits, peradventure cremated.

—A. D.

RUSTICUS SENIOR (Hants).—It is impossible to answer such a question without fuller knowledge of the facts of the case. Many persons of unsound mind, for instance, do not require asylum supervision, nor, indeed, for that matter, constant personal care. For your own protection we should advise you to consult one or more leading alienists.

MR. J. ANJO (St. John's, Antigua).—We are quite unable to accede to our correspondent's request. Our contemporary, *The British and Colonial Chemist and Druggist*, would more likely be able to carry out his request.

DR. H. H. E. is thanked for his note. Enquiry is being made and the result will be communicated.

H. S. (Carlsbad).—The report should first be officially vouched for.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, APRIL 11th.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Discussion on Syphilis (opened by Mr. J. Hutchinson): Syphilis considered in connection with—(1) Mental Disease, Dr. Savage; (2) The Nervous System, Dr. P. Stewart; (3) The Viscera, Dr. H. White.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—5.15 p.m. Meeting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. J. Pardee: Clinique. (Surgical). 5.15 p.m. Lecture:—Mr. J. Cantile: How to Recognise and Treat Abscess of the Liver.

Vacancies.

St. George's Union.—Second Assistant Medical Officer. Salary £120 per annum, with board, residence, and washing. Applications to Dr. J. C. Muir, at the Infirmary.

Borough of Beigate.—Beigate Rural District Council.—Medical Officer of Health. Salary £250 per annum. Applications to the Town Clerk, Municipal Buildings, Beigate.

Royal Hospital for Diseases of the Chest, City Road, E.C.—Resident Medical Officer. Salary £120 per annum, with furnished apartments, board, and washing. Applications to the Secretary.

Cumberland and Westmorland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer. Salary £130 per annum, with board and lodging. Applications to the Medical Superintendent.

Maestfield General Infirmary.—Senior House Surgeon. Salary £100 per annum, with board and residence. Applications to the Chairman of the House Committee.

Ingham Infirmary and South Shields and Westoe Dispensary.—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing. Applications to James R. Wheldon, Secretary, 74 King Street, South Shields.

Salop Infirmary, Shrewsbury.—House Surgeon. Salary £100 per annum, with board, washing, and residence. Applications to the Board of Directors.

Gartloch Asylum, Gartcosh.—Assistant Medical Officer. Salary £125 with board and lodging. Applications to Medical Superintendent.

Royal Halifax Infirmary.—Second House Surgeon. Salary £100 per annum, with residence, board, and washing. Applications to Oates Webster, Secretary, Royal Halifax Infirmary.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Resident Medical Officer. Salary £100 per annum, with board, apartments, and washing. Applications to C. W. Hunt, Secretary, Hardman Street, Deansgate, Manchester.

West Riding of Yorkshire.—Assistant to County Medical Officer. Salary £250 per annum. Applications to Trevor Edwards, Clerk to the Committee, County Hall, Wakefield.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary £150 per annum, with apartments. Applications to the Hon. Secretary, Mr. G. A. Lightfoot, 23 Castle Street, Carlisle.

Liverpool Infirmary for Children.—House Surgeon. Salary £100 per annum, with board and lodging. Applications to Arnold J. Cleaver, Government Buildings, Liverpool.

Royal College of Surgeons of England.—Election of Board of Examiners in Anatomy and Physiology for the Fellowship. Application to the Secretary, 8. Forrest Rowell (See advt.).

Royal College of Surgeons of England.—Election of Examiners under the Conjoint Examining Board in England. Application to the Secretary, 8. Forrest Rowell. (See advt.).

Holloway Sanatorium, St. Ann's Heath, Virginia Water, Surrey.—Junior Assistant Medical Officer. Salary £175 per annum, with board, lodging, washing, &c. Applications to Dr. W. D. Moore Medical Superintendent.

Appointments.

BURLAND, CHARLES, L.R.C.P. and S.Edin., Medical Officer to the Board of Trade for the Port of Glasgow.

DAVIS, F. H., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Dawley District of the county of Salop.

ENGLAND, G. F., M.D. Cantab., Certifying Surgeon under the Factory and Workshop Act for the Winchester District of the county of Hants.

FAIRBANK, H. A. T., M.S.Lond., F.R.C.S.Eng., Orthopaedic Surgeon to Charing Cross Hospital.

FLETONER, J. P., F.R.O.P.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Sherston District of the county of Wilts.

HOWARD-JONES, J., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Worthen District of the county of Salop.

LAMBERT, FREDERICK SAMUEL, M.R.C.S., F.R.O.P.Lond., Medical Officer to the Lincoln Post Office.

LEWIS, CYRIL, M.D., C.M.Edin., Honorary Assistant Physician to the Cardiff Infirmary.

PATERSON, DONALD ROSE, M.D., C.M.Edin., M.R.C.P.Lond., Honorary Surgeon to the Ear, Throat, and Nose Department at the Cardiff Infirmary.

RIDOUT, C. A. SCOTT, M.S., M.B.Lond., F.R.C.S.Eng., Honorary Pathologist to the Royal Portsmouth Hospital.

SHEPPARD, ARTHUR LEWIN, M.B., B.S.Durh., House Physician at the Bristol Royal Infirmary.

SMITH, L. BRINGLETON, L.R.C.P.Lond., M.R.C.S., Junior House Surgeon at the Bristol Royal Infirmary.

WRIGHT, A. J., L.R.O.P.Lond., M.R.C.S., Casualty Officer at the Bristol Royal Infirmary.

Births.

BROOKS.—On April 4th, at the Elms, Penn Road, Wolverhampton, the wife of J. Pratt Brooks, M.R.C.S., of twin sons.

HYALOP.—On April 1st, at Castle Hill House, Settle, the wife of B. B. Hyalop, M.B., of a son.

SMITH.—On April 4th, at 204 Selhurst Road, S. Norwood, the wife of W. H. M. Smith, M.R.C.S., L.R.C.P., of a son.

THOMPSON.—On April 2nd, at The Marlowes, Hemel Hempstead, Herts, the wife of Maitland Thompson, L.R.C.P., M.R.C.S., of a son.

Marriages.

COTTER-MUSSON.—On April 7th, at St. Peter's Church, Fulham, George Edmond Westworth Cotter, M.A., M.B., B.C.Camb., M.R.C.S., L.R.O.P.Lond., son of the late Duncan Donald Darroch Cotter, West Indies, to Muriel Isobel, youngest daughter of Samuel James Musson, of Norwood.

HURST-BAUMANN.—On March 10th, at Savannah, Georgia, U.S.A., Walter Hurst, M.D., B.Sc., L.S.A., and Alice Heselbine Baumann, M.D.

Deaths.

BRETtingham.—On March 31st, at Lyndhurst, Oldfield Park, Bath, Charles Brettingham, M.R.C.S., L.S.A., late Surgeon Bengal Army.

EVANS.—On March 28th, at Zanzibar, Wilfred F. Evans, M.R.C.S., L.R.O.P., fifth son of the late Nicholl Evans, M.D., of Chestnut, Herts.

HILBERS.—On April 7th, at 60 Brunswick Place, Hove, Brighton, Louisa Susannah, widow of George James Hilbers, M.D., aged 88 years.

KIDDLE.—On April 7th, at Locks Heath House, Salisbury, Hants, John Nelson Kiddle, L.R.C.P., formerly of Albert Hall Mansions, London.

SHIPLEY.—On March 16th, at Secunderabad, India, of peritonitis, Edith, wife of Major C. T. Shipley, Royal Fusiliers, and daughter of the late Surgeon-General J. T. C. Ross, C.I.E.

STONEV.—On April 6th, at The Heath, Abbeyleix, Mary Anne, wife of Hugh B. Stoney, M.B.

THE MEDICAL PRESS AND CIRCULAR.

WEDNESDAY, APRIL 18, 1906.

No. 16.

NOTES AND COMMENTS.

The Central Midwives Board and Ward Cousins from the last meeting of the Central Midwives' Board, the resolution standing in their name was postponed. This reads as follows: "No one shall be permitted to begin the course of instruction, either theoretical or practical, until she has produced evidence satisfactory to the Central Midwives' Board that she has received sufficient elementary education to enable her to read a text-book and take notes of cases. But this rule shall not apply to pupils who have received training in general nursing for at least one year." It is a curious commentary on the composition of the Board that such a resolution should not only be necessary, but that opposition to it must be expected. Its opponents apparently believe that seeing there is a dearth of properly qualified midwives, it will be well for the Board to cast its net so wide as to include the mentally halt and maimed. One lady member of the Board apparently does not think much of "registered medical practitioners," and reasoning from her opinion of them, advocates the introduction of any class of nurse.

Alice in Blunderland—A New Edition. An unpublished fragment of this caustic work has recently reached us, and may be of interest:—"Next moment Alice found herself in the middle of a large plain, entirely occupied by rather overgrown cabbages, the Red Queen was by her side. Each cabbage held out an attenuated side-stalk, with which it supported a book. 'Please,' said Alice, 'What are these funny cabbages doing?' 'Doing,' said the Red Queen, 'can't you see? They are learning their lessons.' 'But,' said Alice, 'some of them are asleep, and such a crowd of them have their books turned upside down. And, oh! look at that poor old dear, I think she is blind.' 'It's no matter,' said the Red Queen sarcastically, 'they couldn't read even if they were awake. They never learnt how.' Alice felt inclined to say 'Rubbish,' but she prudently held her tongue instead, and, on releasing it, murmured plaintively, 'Then, how *can* they learn their lessons?' 'They can't,' said the Queen, 'but the Board like it. They make a crowd, and that is so useful, you know. And then,' she added, as an after-thought 'they pay fees.' Alice said nothing."

The Normyl Cure for Drunkenness. Is there any drug cure for drunkenness? Most medical men of experience would answer "No," without a moment's hesitation. The only hope for the chronic inebriate is to brace up his moral fibre and to help him by placing him in an

environment as free as possible from temptation. But where medical men pause on the brink there are always laymen ready to plunge in. Curiously, some of the most ardent of these amateur practitioners are clergymen, who by some strange freak of providence seem to assume a divine right of knowledge of medicine, albeit one of the most difficult, technical, and absolutely responsible of all the learned professions. If there be one thing above all others that is daily forced upon the attention of the medical man, from the first day he enters the hospital to the last day of his active professional life, it is the subject of alcoholism. Its effects, physiological and pathological, upon mind and body are ever before him in the human wreckage of the out-patient and casualty rooms, the wards and the *post-mortem* theatre.

Medical Men know no "cure" for Alcoholism. Yet in spite of the careful study of alcoholism medical men have no cure by drugs. The usual clergyman, however, has rushed into the breach, in the shape of the Reverend Hugh B. Chapman, Secretary of the Normyl Treatment Association for the Cure of Alcoholism. Recently, at a public meeting in Newcastle, he stated that before becoming connected with the society he had tested the treatment upon 230 patients, of whom 220 were cured. If that be a true statement Mr. Chapman deserves a municipal statue in enduring brass, as one of the great benefactors of humanity. Alas! the Normyl physic is a secret remedy, and it is not easy to accept the statement of the Secretary that no pecuniary benefit is obtained from the sale of the medicine. In that case, why keep the composition secret? Medical men keep nothing secret; why, then, should a clergyman observe a less humane and generous code in his ethical relations to society? If no one makes any money out of Normyl, why not give drunkards all over the world a chance of getting salvation?

Proprietary Drink Curses. The reverend gentleman, we believe, appeared on the scene at a somewhat advanced stage of the Normyl Company's development. In its earlier days we were amazed at seeing the names of several leading members of the medical profession connected with the venture. We wrote to them and some approved the "cure," and stated they had sent patients for treatment. This is a sober statement of fact, and yields an extraordinary glimpse of the inner life of our profession. The Normyl method is one of many that have been advanced from time to time. Unlike Normyl, most of these nostrums are based on a frankly commercial footing. Nearly all of them depend upon the administration of narcotic drugs, at

times hidden under the cloak of some rare or costly medicament. We are glad that several Newcastle medical men attended the meeting and told their fellow townsmen what they thought about drink cures in general and the Normyl plan in particular. There is nothing more likely to appeal to the weak and the gullible than these so-called cures for inebriety. If Mr. Chapman is so firmly convinced of his results let him organise an authoritative medical investigation. The subject is important enough.

LEADING ARTICLE.

ANTISEPTICS IN MEDICINE.

THE supreme importance of Listerian methods in modern surgery is so universally recognised that it seems trite to point out that next to the discovery of anæsthetics, that of antiseptics has probably conferred the greatest boon upon suffering humanity. The malign influence of pathogenic organisms is, however, equally at work in those affections which do not directly fall within the province of the surgeon. There are many purely medical disorders which owe their origin to the development of germs and their elaborated toxins within the body, but it is only within comparatively recent times that oral sepsis has been proved to be the cause of such grave affections as pernicious anæmia. The better observance of oral hygiene, together with the application of antiseptic principles to the buccal cavity, is now, happily, being carried out by an increasingly large number. As far as the alimentary canal is concerned, it cannot be denied that the bacterial flora of the human intestine is of considerable importance, and it would appear that even the *bacillus coli* itself has certain functions to perform in connection with undigested food which are advantageous to the body as a whole. The virulence of these intestinal organisms may be enormously increased under abnormal conditions, whereby such affections as peritonitis, colitis, and dysentery may be set up. The administration of the so-called "intestinal antiseptics" may be of doubtful value theoretically, but the fact remains that such substances as β -naphthol or salol are not altogether without salutary effect in states of severe intestinal sepsis. The application of the antiseptic principle to medicine is a subject of very wide importance, touching, as it does, many common diseases which come within the ken of the physician. As Sir Richard Douglas Powell pointed out some time ago, it is septic organisms which cause such havoc in pulmonary tuberculosis by interfering with the natural tendency of the disease to become fibrotic. Similarly, the same germs are responsible for keeping up what would otherwise be a simple bronchitis. The position at which we have now arrived in the treatment of tuberculosis of the lungs in sanatoria may, indeed, be said to consist in an organised attempt to deprive the patient of all added infection in the shape of septic organisms and to preserve his environment in as aseptic a condition

as possible. The creosote preparations are of indisputable value in assisting to bring about the desired end, and where the open-air cure is out of the question saturation of the system by these compounds up to the limit of toleration is one of the best modes of treating the disease. We know that if the tubercle bacillus be rigorously let alone it will almost surely become surrounded by an area of fibrosis which, in other words, is Nature's effort to cure the complaint. The principles of antiseptics may well be said to belong equally to medicine and surgery. Modern observers have also laid stress upon another point of practical importance, namely, that too careful a preparation for any surgical operation, especially a major one, cannot be made. A few days of rigid dieting and attention to the functions of the bowels may make all the difference between the success or failure of an operation, and it would frequently seem that when the latter is undertaken in a hurry without such preparation septic complications arise, no matter how aseptic the surgery may have been. The physician who fully recognises the part played by septic organisms in non-surgical affections is far more likely to meet with success in his treatment than the practitioner to whom antiseptics is a name only.

NOTES ON CURRENT TOPICS.

Cremation.

THE progress of cremation is matter of no little interest and concern to medical men. With the flocking of people into towns, and the consequent expense of land in the neighbourhood of towns, the difficulty of getting suitable sites for cemeteries is an increasing one, and it is impossible on hygienic grounds to justify the practice of burying the dead deep in the earth in strong or impermeable coffins, which must sooner or later give way and pollute the subsoil in the neighbourhood of living-houses. Earth to earth burial in the living humus of the soil is doubtless the most economically and hygienically unobjectionable way of disposing of the dead, but practice and sentiment are all against such a plan. Cremation is, therefore, the most convenient half-way house, and it is slowly creeping into favour with the public of the Western world. From a paper read by Dr. Killick Millard, at the provincial sessional meeting of the Royal Sanitary Institute at Leicester, it appears that in Paris up to the end of 1903, the number of cremations was 3,147, and since then it has largely increased. In the United States the number for 1902 was 3,160, and in Germany in 1903, 1,074. So far in Great Britain 5,020 cremations have taken place, of which 476 were in 1903, 506 in 1904, and 604 in 1905. The bodies have practically all been those of people in the upper and middle classes, probably by reason of the expense as much as by reason of education; but the figures suggest that the primitive custom of burning the dead will soon become a popular one in the present century.

London Consumptives.

THE difficult question of how to deal with the London consumptive, that is, if he has to be dealt with officially, has passed through one phase of its existence. It will be remembered that a short time ago an influential deputation, led by Sir William Broadbent, waited on the Metropolitan Asylums Board with the suggestion that the Board should become the tuberculosis authority for the metropolis in the same way that it is now the fever and small-pox authority. The Board have evidently been much exercised over the enormous responsibility of such a charge, as indeed they well might be, and lately they applied to the Local Government Board for advice. The latter have just replied that the information before them at the moment does not appear to afford sufficient justification for the heavy outlay which would be involved by the proposal, and we learn that Sir William Broadbent himself has seen reason to modify his suggestion that the Metropolitan Asylums Board should be the authority for the purpose. All thinking men who are sensible to suffering and to the devastation consumption is causing in London wish to see the problem of tuberculosis tackled firmly, but it is certainly a matter for deep reflection as to whether the wholesale provision of sanatoria at a crushing expense to the ratepayer would do more than touch the fringe of the evil. It is necessary to keep clearly in mind that unless the prospects of restoration to health for the tuberculous were very much greater than appears at present from sanatorium returns, no scheme that was even approximately self-supporting could be expected. And if the community is to take on its shoulders the care of its consumptives, it should do so with full knowledge of what it has to expect. Otherwise only disappointment and chagrin would result.

International Congress of School Hygiene.

A PRELIMINARY meeting has been held in the London University Buildings with a view to attracting interest in the proposal that the second International Congress of School Hygiene shall be held in London next year. The resolution to that effect was moved by Lord Reay, and carried unanimously, and we hope that the necessary sum, namely, £4,000, will be forthcoming to ensure the success of the undertaking from the financial standpoint. As Mr. Birrell aptly remarked in introducing the Education Bill, the interest of people generally seems to centre in the sectarian controversies connected with elementary education rather than in the measure for promoting the attainments and health of the children. The medical profession can afford to let the various religious bodies fight their own battle on the subject of denominationalism, if they can attract the sympathies of all parties towards the study of the mental and physical health of the rising generation. It is beyond question that Great Britain and Ireland are far behind many Continental and Colonial countries in their arrange-

ments for the improvement of the conditions of elementary school-children, and the bringing together of a number of educational experts from those countries to London would supply a keen incentive to the study of school hygiene over here. It would be lamentable to have to record that for want of funds so rich a city as London was unable to entertain the proposed Congress.

Home Spas

BIG Englanders and Little Englanders can congratulate each other in the attempt that is being made at the International Health, Food and Hygienic Exhibition, at the Crystal Palace, to bring before the people of this country the striking fact that Great Britain contains certain spas and watering places at least as conducive to health as the fashionable resorts of the Continent. Our enterprising neighbours in Germany, France, Italy, and Switzerland have long realised the potentialities of the spa-business, and any little town or village that possesses a spring or a peculiar species of mud knows how to make a fortune out of them, and our own people are beginning to wonder why English sulphur and Scotch chlorides should not prove equally profitable. In the *Health Resort* this month, it is stated that £15,000,000 is spent annually by visitors, most of whom are British, in travelling in Italy. If this be so, there would seem to be no logical reason why Italians should not spend at least half that sum in exploring the benefits of our Northern clime. There is, however, fashion in health-seeking as in drugs and treatments, and we fear that until the German Emperor or the King of Spain can be induced to take a course of baths at Harrogate or Buxton people will prefer Homburg and Marienbad to the attractions of their native spas.

Expert Pathologists and Medico-Legal Cases

A CONFERENCE of pathologists was convened some time ago at the instance of the Medico-Political Committee of the British Medical Association to discuss the position practising pathologists should adopt in regard to inquests and other medico-legal inquiries. The conclusions arrived at are published in a recent number of the *Supplement* to the Association's *Journal*, and are such as will receive general approval. It is suggested that the employment of expert pathologists to assist in *post mortem* examinations in cases of special difficulty is highly desirable, but that the employment of such an expert is to be regarded as in addition to, and not in substitution of, the employment of the medical man who has attended the patient during life. This is quite as it ought to be. The medical man in attendance is, or may be, in possession of evidence which may be of the highest importance, and without which the pathological findings would be meaningless. The truth is best discovered in medico-legal as in ordinary medical cases by a collation of the clinical and pathological facts. The conference also demands that proper

remuneration should be given for expert work and a minimum fee of five guineas for *post mortem* examination and evidence is suggested.

National League for Physical Education.

THE National League for Physical Education and Improvement lately sent a deputation to the Minister for Education for the purpose of urging on him the duty of initiating a scheme for the systematic medical inspection of school-children, and for the establishment of a regular record of anthropometric observations in the rising generation. Mr. Birrell, in reply, expressed his sympathy with the objects of the league, but said that, considering the expense of setting such a scheme on foot the Government would have to be convinced of its practical utility and its general approval. From the point of view of the medical profession, such approval will be generally given on the principle of the old maxim that prevention is better than cure. But it follows as a necessary corollary to such a plan that the result of the observations so made should be something more than a pious record which would be filed in the spacious cellars of a Government office. Observations on the physical condition of children connote steps that should be taken to remove defects and to prevent degenerative processes continuing. If the league could work out a good, economically sound scheme by which work of this kind might be carried out, they would deserve well of their fellows. The cost of medical inspection, if made by qualified practitioners, should be easily recouped by the diminution in the cost of infectious disease administration, and it should not be impossible on these lines to devise a plan which would earn general regard.

Nursing Home Charges.

THE expenses attached to the maintenance of the ordinary "nursing home" are necessarily heavy, especially in fashionable town quarters, where rents are forced up by landlords to the highest possible pitch. At the same time in many such private institutions the charges are often excessive, not to say extortionate. A correspondent has sent us the account tendered by the proprietress of a well-known private nursing home in a smart town on the banks of the Thames. The patient was a small boy some five or six years of age, suffering from German measles. He was in the home for ten days, and the account tendered was for £23 18s. 6d. The fees were two guineas a day for the patient, with £3 3s. a week for a special night nurse, and £1 1s. for her board. The latter items were charged for the first week only, and the total amount was made up of various small fees. Most middle-class folk would agree with the mother in regarding a charge of £23 18s. 6d. for ten days nursing of a small boy with a trivial complaint as excessive. Compared with average medical charges, the scale is simply one of stupendous liberality. The moral is that, before sending a patient to a nursing home, the

medical practitioner will do well to ascertain precisely the scale of fees and to see that the patient's friends are fully informed of the liabilities they are incurring. In this way a deal of trouble and vexation will be prevented.

Barber's Rash.

A RECENT County Court case in which a customer obtained £15 damages against a West End barber, naturally raises the whole question as to the origin and prevention of that cutaneous affection of the face usually known by the name of "barber's rash." Strictly speaking, the term is applicable only to that form of ringworm of the beard region formerly known as "tinea barbæ," or "barber's itch." Sycosis of the face is known to be either hyphogenic, due to lodgment of a trichophyton, fungus in the hair-follicles, or coccigenic due to microbic infection of the skin with pyogenic cocci. The latter organisms find no difficulty in gaining access to the dermal tissues through the minute abrasions inflicted by the razor. It is an established pathological fact that the ordinary white coccus of the human skin, in itself harmless, may, under certain conditions, take a virulent form, so that even if the razor be sterile this germ might be inoculated into the skin, there to produce all its evil effects. The papules and pustules characteristic of the disease do not always appear immediately, though patients sometimes state that they have experienced a sensation of itching after returning home from a barber's shop. The diagnosis between the two different forms of sycosis is not always an easy matter, the microscope being generally necessary for examining thickened hairs, &c. Some people will say, of course, that any skin eruption whatsoever coming on after a visit to a barber is a "barber's rash," though this by no means follows. A too hasty pronouncement of infection from shaving implements may lead an innocent individual into serious trouble, for, given a sterile razor and all the appurtenances of the rasorial operation strictly in accordance with modern aseptic methods, it does not follow that the customer may not develop some irritation, the cause of which lies in his own skin.

Home-Made Galenicals.

FOR a generation or more the making of pharmaceutical preparations has been steadily going out of the hands of the dispensing chemist and druggist into those of the wholesale manufacturer. On the whole, the public gains by a supply of cheaper and better drugs. In the single instance of pills, an enormous saving of time and far greater precision of dosage is effected by the substitution of machine for hand-made labour. At a recent meeting of the Sheffield Pharmaceutical Society, Mr. W. H. Stiles, of Doncaster, read a paper on "Home-Made Galenicals." He deplored the fact that the practice of making pharmaceutical preparations was rapidly going over to the wholesale houses. That state of things, he maintained, was neither creditable to the improved educational

facilities possessed by the modern therapeutical student, nor advantageous to his pocket nor his self-respect when he became a principal. While accepting his statement that with intelligent care galenicals at least equal to those sold by the wholesale manufacturer could be made by any retail pharmacist worthy of the name, we doubt if they could be furnished at anything like an equal cost. Division of labour is an inexorable law, and has settled this question long ago. At the same time it seems more than likely that an energetic chemist might save himself a great deal of money by making many of the simpler galenical preparations in his own pharmacy.

The Gynæcological Bath.

THE examination of the pelvic organs of women is always a more or less disagreeable business, both to patient and doctor, and for accurate diagnosis and the relief of discomfort the administration of an anæsthetic is frequently resorted to. But every anæsthetic has its risks, and in any case the patient has to be confined to bed for a day or two to get rid of the effects. Moreover the administration of an anæsthetic does away with an important factor, namely, the woman's sensation, and in many cases tenderness on palpation is in itself a valuable guide to diagnosis. Dr. Profanter, in a recent number of the *Wiener Klinische Wochenschrift*, proposes a way out of these difficulties which is as original as it is refreshing. He suggests that women should be examined in a semi-recumbent position in a bath filled with warm water. The heat of the water relaxes spasm of the abdominal muscles and allays local tenderness, whilst at the same time the vagina may be distended with water so that the finger can be easily inserted. There is a *naïveté* about the plan which almost moves us to mirth. The idea of a gynæcologist having his consulting-room fitted up as a kind of aquarium, whilst he, suitably attired, pursues his patients, also suitably attired—we trust, through the deep waters of his tanks, is capable of considerable extension. Sir James Barr, of Liverpool, still adheres to his tank treatment of typhoid, we believe, and if the system were applied on Dr. Profanter's lines to other departments we might eventually conduct our confinements in baths and teach children to swim before they could walk. But at present, at the risk of being thought to be reactionaries, we cannot declare ourselves adherents of the blue-water school of gynæcology.

A Prescribing Chemist.

IN the long run dispensing chemists who take upon themselves the illegal prescribing of drugs will inevitably bring their calling into disrepute. After all it is to medical men that they should look for their main support, but they are not likely to strengthen the bonds of good feeling with the profession by usurping their proper function. It would be well for all concerned were coroners to speak out freely upon the subject of irresponsible

prescribing. Not long ago the Manchester Coroner held an inquiry upon an aged woman who died from peritonitis shortly after taking a pill prescribed and dispensed by a chemist who had not even seen the sick person. In the report in the *Manchester Guardian* we find the statement that "the chemist told the coroner he had been in the habit of prescribing for simple cases, and from the information given him by the woman's daughter he did not think he would be doing his duty had he not given her something to relieve the old lady." Medical evidence showed that the drugs given "would tend rather to aggravate her condition than do otherwise." The fact remains that this chemist prescribed for a woman drugs that probably hastened if they did not cause her death. His act was illegal, and does not in substance materially differ from that of any unqualified charlatan who has not passed an examination in pharmacy.

PERSONAL.

WE offer our sincere congratulations to Sir William and Lady Crookes, who celebrated their golden wedding on April 10th.

H.R.H. THE PRINCESS ROYAL has consented to receive purses with donations to the fund now being raised to build the first wing of the reconstructed Bolingbroke Hospital, on the occasion of the laying of the foundation-stone on Saturday, May 5th.

DR. W. J. SIMPSON has left for India, having been asked by the Colonial Office, on behalf of the Government of the Straits Settlements, to inquire into, and to report on, the sanitary condition of Singapore.

UNDER the presidency of Sir Frederick Treves, President of the British Red Cross Society, an International Congress of Red Cross Societies will be held in London for one week in June, 1907.

MR. PETER WILLIAMS, M.R.C.S., of Ferryside, Carmarthenshire, was recently presented with a cheque for £300, and his wife with a silver salver, by a number of friends and patients as a mark of their esteem and respect.

ON May 25th, Dr. Leonard Hill will deliver a lecture at the Royal Institution of Great Britain, on "Compressed Air and its Physiological Effects."

WE regret to learn that Lieutenant Forbes Tulloch, of the R.A.M.C., a popular young officer, accompanying the Royal Society's Commission sent to Uganda to investigate the mysterious "sleeping sickness," has accidentally contracted the disease while dissecting a rat.

MR. GERALD QUIN LENNANE, L.R.C.P., F.R.C.S.I., was elected on Wednesday last as medical officer of health for Battersea, at a salary of £600 a year. There was keen competition for the post, but as the successful candidate had been in private practice in Battersea many years, and was formerly a member of the Battersea Vestry, his election was considered to be fairly assured.

DR. ROBERT JONES, M.D., M.R.C.P., has been appointed Lecturer on Mental Diseases at the Westminster Hospital. Dr. Jones is the Resident Physician and Superintendent of the London County Council Asylum at Claybury, and President-Elect of the Medico-Psychological Association. He is the author of many works and papers on delusions and other forms of insanity.

A CLINICAL LECTURE ON MITRAL STENOSIS.

Delivered at St. George's Hospital on March 20th, 1906.

By H. D. ROLLESTON, M.D.Cantab., F.R.C.P. Lond.,

Physician to St. George's Hospital, Physician to the Victoria Hospital for Children.

This patient, a boy, æt. 14, came in with an acute articular rheumatism, which rapidly yielded to salicylates. He was given 15 grains of salicylate of soda, with double the quantity of bicarbonate of soda every hour for six hours, and then once every four hours. The addition of a full dose of alkali is a remnant of the "alkaline treatment of rheumatism" originated by the late Dr. Fuller, of this hospital, which was the most successful method of treating rheumatic fever before the days of the salicylate. The addition of full doses of an alkali probably has the great advantage of diminishing the incidence of cardiac complications; thus a series of cases in this hospital ten years ago, tabulated by the late Dr. Lee Dickinson, showed that cardiac complications were more frequent in a series of cases treated with salicylates alone than in a corresponding series of cases treated with salicylates and alkalis. For this purpose I much prefer to use bicarbonate of soda rather than bicarbonate or citrate of potash, because the soda salt is less depressing than the potash. Frequent doses of salicylates alone, such as are required in order to combat the acute stage of rheumatic fever, not uncommonly set up vomiting. Some years ago the sister of the ward told me that she always expected cases of rheumatic fever treated with salicylates alone to vomit after the medicine. Very probably this vomiting is due to the irritation of the stomach, set up by the liberation of the salicylic acid; if this be so, the addition of alkali should prevent the formation of free salicylic acid, and so obviate vomiting. In addition, I now always give tincture of capsicum, 1 minim, which, probably by producing slight counter-irritation of the stomach, neutralises the irritating effect of salicylates. At any rate, vomiting is seldom seen in cases treated in this way. In passing, we may refer to the other toxic effects of salicylates. As they relieve pain, it is not unnatural that they should modify sensation in other ways; thus, as is well known, salicylates produce deafness and ringing and buzzing in the ears. Sometimes the nervous effects are more marked, and the mental depression, which often follows salicylates, may pass into a peculiar form of aberration, most commonly seen in women, and accompanied by manifestations of suspicion, such as the belief that the food or medicine is poisoned. We may compare the alteration of taste, which probably is the basis for this delusion, with the impairment of auditory sensation mentioned above. In some cases salicylates cause marked shortness of breath, thereby arousing a suspicion of cardiac dilatation.

When this patient was admitted his heart was found to be definitely affected with established but compensated mitral stenosis. Although there was no history of previous rheumatic fever some form of rheumatic infection must have occurred in the past to account for this mitral stenosis; for this form of heart disease takes months to develop, and therefore could not have developed on this occasion. In this way mitral stenosis contrasts with mitral regurgitation, or with aortic regurgitation, though this is less commonly seen in these circumstances, both of which may develop within a few days of the commencement of an attack of acute rheumatism. In the vast majority of cases mitral stenosis is rheumatic in origin, but it often occurs in cases in which the articular manifestations were slight, and as a result there is no history forthcoming to point to rheumatism. In a number of patients it follows chorea, which we may

regard as rheumatism of the cortex of the brain. This probably accounts for the fact that, whereas ordinary rheumatism is, if anything, commoner in males, mitral stenosis is much commoner in females, the increased incidence of chorea and mitral stenosis in the female sex being thus correlated. Other causes of mitral stenosis are of subordinate importance. Chronic valvulitis, due to long-continued high blood-pressure, such as occurs in the left ventricle in cases of arteriosclerosis and glandular kidney, sometimes leads to a certain amount of narrowing of the mitral orifice, though as a rule there is retraction of the segments of the mitral valve which of course produces dilatation of the orifice. It has been thought that anæmia may be the cause of mitral stenosis in the following way. Anæmia gives rise to dilatation of the left ventricle and mitral regurgitation, and, as a result of the irritation thought to be thus set up, to a certain amount of chronic valvulitis, the chronic valvulitis resulting in the welding together of the segments and eventually in stenosis. This hypothesis, however, is very doubtful and it is perhaps more probable that both the anæmia and the stenosis are the effects of the rheumatic virus, which has not given rise to any articular manifestations. In a few cases, practically pathological curiosities, an adherent clot, forming a pedunculated mass in the auricle, may become so elongated as to project into and narrow the mitral orifice. Lastly, it is often said that mitral stenosis is congenital; if so, it is of the greatest rarity; in short, it is safe to assume that in the vast majority of cases mitral stenosis is rheumatic in origin.

The physical signs of mitral stenosis are of great interest, both because they are variable and because of the interpretation which may be put upon them. In a pure case of mitral stenosis the apex beat of the heart is internal to the normal position. This depends on the fact that a smaller quantity of blood than normal passes into the left ventricle, the left ventricle has less work to do and therefore undergoes a certain amount of atrophy. At the apex there is a presystolic thrill. It is important to distinguish a thrill produced inside the heart from one which is produced in the chest wall, and is due to the greater pulsation of the intercostal spaces than of the rigid ribs, a condition which often occurs in cases of forcibly beating hypertrophied hearts. A thrill of this kind which may be called an exocardial, false, or pseudo-thrill, is often felt when the palm of the hand, as distinguished from the fingers, is placed lightly over the chest wall. A true thrill is one produced inside the heart, and can be felt when the individual fingers of the hand are separated from each other and placed over the intercostal spaces. If a thrill which is felt by the whole hand disappears when the fingers are placed separately over the intercostal spaces, we may conclude that it is produced in the chest wall and not in the heart.

In mitral stenosis the cardiac dullness is increased upwards, and instead of beginning at the lower border of the fourth costal cartilage on the left side occupies the third, or second left, intercostal space close to the sternum. This upward extension of the cardiac dullness, which used to be referred to dilatation of the left auricle, is undoubtedly caused by dilatation of the upper part, or conus arteriosus, of the right ventricle. Pulsation can often be felt over this area of the pulmonary artery, and a shock, due to the more forcible closure of the pulmonary valves, is perceived.

The murmurs of mitral stenosis occur during the

diastole of the heart; there may be a long continuous murmur, occupying nearly the whole of the diastole; in other cases there may be a murmur occupying the commencement, the middle, or the end of the diastole. The presystolic murmur—which, being produced by the contraction of the auricle, has been called the auricular systolic—has also been termed the crescendo murmur by those who wish to avoid committing themselves to the view that it is presystolic in time. It has the characteristic harsh vibratory character of other obstructive murmurs, such as those of pulmonary stenosis and aortic stenosis, the vibrations being so coarse that they can be felt as the presystolic thrill, as well as heard. The presystolic murmur is very variable, and may come and go, so that it may be audible in the morning and absent in the afternoon. It may be well to point out that a presystolic murmur, though generally evidence of mitral stenosis, is not absolutely pathognomonic of that condition. It may occur in other cardiac lesions. The most frequent of these is free aortic regurgitation, in which a murmur, called Flint's murmur, is produced, although there is no organic narrowing of the mitral orifice. As just mentioned, it occurs in cases of free aortic regurgitation, and is explained on the supposition that the column of blood, regurgitating from the aorta, impinges, when entering the left ventricle, on the anterior or aortic cusp of the mitral valve and either bulges it inwards, producing temporary narrowing of the mitral orifice at a time during which blood is flowing from the left auricle into the left ventricle, or sets up vibrations in the mitral valve which are audible as a murmur. A presystolic murmur is also occasionally heard in cases of adherent pericardium, especially in children, and in some cases in which dilatation of the left ventricle is all that is found after death.

The mid-diastolic murmur is audible at the apex as a short murmur immediately following the second sound, so that the condition resembles that of reduplicated second sound at the apex. In order to distinguish between a reduplicated second sound and a mid-diastolic murmur, the condition of the second sound at the base of the heart must be examined. If there is no reduplication of the second sound at the base of the heart, where the second sounds are produced, what appears to be a reduplication of the apex must be due to the addition of the abnormal sound or murmur after the second sound. This mid-diastolic murmur is also rather unfortunately called the post-diastolic murmur, the term "post-diastolic" meaning *after the diastolic or second sound*, and not after the whole period of diastole. It might, perhaps, be naturally thought that "post-diastolic" means after the period of diastole, and so was equivalent to systole. But if the term "post-diastolic" is used at all, it means *after the second sound and before the first*, just as the term "post-systolic" means a murmur *after the systolic or first sound*, i.e., a murmur between the first and second sounds, a condition which is sometimes spoken of as reduplicated first sound. A mid-diastolic murmur is very common in mitral stenosis, especially in cases like this one, where the compensation is good. The causation of a mid-diastolic murmur is, I believe, that during diastole the negative pressure which is produced by the expansion of the left ventricle, sucks the blood in through the narrowed orifice and so produces a murmur.

The early diastolic murmur of mitral stenosis replaces the second sound, is audible on the left side of the sternum, is soft in character, and resembles a regurgitant aortic murmur heard in an abnormal position. This murmur, which is the least common of the three diastolic murmurs met with in mitral stenosis, was described, before the presystolic murmur was recognised, by Dr. Hope, who was the first assistant physician appointed (in 1834) at St. George's Hospital. It is therefore called Hope's murmur. It is probably produced as the result of temporary pulmonary regurgitation (Graham Steell), due to over-stretching and dilatation of the pulmonary artery, which prevents

the valve segments, although they may be perfectly healthy, from coming in contact.

From this description of the diastolic murmurs of mitral stenosis, it is obvious that difficulty may arise in deciding (1) whether in a case of aortic reflux a presystolic murmur present points to concomitant mitral stenosis or is only a "Flint's murmur"; and (2) whether in a child with mitral stenosis a soft early diastolic murmur on the left side of the sternum is to be regarded as evidence of some degree of aortic regurgitation or is only "Hope's murmur," due to temporary pulmonary regurgitation. In cases of this kind a decision may only be possible after most careful consideration of all the cardiac signs.

The other modifications of heart sounds, in mitral stenosis, are accentuation or reduplication of the second sound in the pulmonary area. The importance of recognising accentuation in the pulmonary second sound is that it gives a guide to the state of compensation. As long as the compensation, namely, the hypertrophy of the right ventricle, is able to hold its own, the pulmonary second sound is accentuated. When the compensation begins to fail, in other words, when the right ventricle begins to dilate, so that the tricuspid regurgitation follows, the blood-pressure in the pulmonary artery falls, and the second sound, from being greatly accentuated, becomes weak. The first sound of the heart at the apex is generally short and sharp in mitral stenosis; so that in cases where the presystolic murmur and a short first sound are audible, the mistake sometimes arises of regarding the murmur as systolic and the short first sound as being a normal second sound.

Three stages of mitral stenosis are usually described. In the first stage the compensation is perfect and we hear a presystolic murmur, a fairly normal first sound, followed by a second sound at the apex, an accentuated second sound over the pulmonary artery, and a rather feeble second sound over the aortic area. In the first stage of mitral stenosis the patient has few or no symptoms, and the condition may be found accidentally in a patient who comes to the hospital for some other cause. In the second stage of mitral stenosis the compensation is strained, the patient is short of breath on exertion, and prone to get bronchitis. Such a patient attends in the out-patient room, and is not sufficiently ill to be admitted as an in-patient. The physical signs are a presystolic murmur, followed by a short, sharp first sound, but no second sound, at the apex; great accentuation or reduplication of the pulmonary second sound, some dilatation of the right ventricle, as shown by the epigastric pulsation, and increase of cardiac dulness to the right of the sternum. In this stage the mid-diastolic and early diastolic murmurs may alternate with the presystolic murmur, so that at one time a presystolic murmur may be present at another time absent and replaced by one of the other two. In perhaps the great majority of cases of mitral stenosis there is concomitant mitral regurgitation and a systolic murmur is also present, but for simplicity we have dealt with pure mitral stenosis. As Dr. Graham Steell pointed out some years ago, the murmur most often present in cases showing mitral stenosis after death is a systolic apex murmur, which differs from that of uncomplicated mitral regurgitation in not being audible at the inferior angle of the left scapula.

In the third stage of mitral stenosis, or in the stage of ruptured compensation, the signs strictly characteristic of mitral stenosis have disappeared, and the patient is really suffering, not merely from mitral stenosis, but from the effect of that disease—namely, tricuspid regurgitation.

I will make a few remarks only about some of the results and complications. From backward pressure the left auricle becomes dilated, and by pressing on the left bronchus it may give rise to cough, and, as a result of a certain amount of narrowing of the bronchus, to harsher breathing over the left bronchus than over the

right. This sign may often be found, if looked for, in cases of mitral stenosis. Dilatation and stagnation of blood in the left auricle may be followed by clotting of the blood, especially in the auricular appendix. Blood clots so formed are adherent, but they may become detached, and, by passing into the general circulation, give rise to embolism, and so to important complications.

Embolism of the first branch of the aorta—namely, the coronary artery—very seldom occurs in mitral stenosis; when one of the main branches of the coronary artery is blocked in this way sudden death results. Embolism of the middle cerebral artery, by cutting off the blood supply to the brain, gives rise to anæmic softening of the brain, and hemiplegia. The arteries at the base of the brain being badly supported, the impact of an embolus, although the embolus is simple, or non-infective, may be followed by the production of an aneurysm. This production of an aneurysm is analogous to the formation of an aneurysm at the site of ligature, a very rare event. Embolism of the arteries at the base of the brain, occurring in young women, should always be regarded as probably of embolic origin. Embolism of a cerebral artery may be followed by rupture of an aneurysm. So that a patient with mitral stenosis may have one attack of hemiplegia, due to embolism, followed subsequently by a severe epileptiform attack, due to rupture of an aneurysm and extravasation of blood on the surface of the brain. As a rare but interesting incident, embolism of the central artery of the retina, giving rise to loss of vision in the part of the retina affected, may be mentioned.

Embolism occurring in the kidney and spleen gives rise to the production of infarcts; as the organs have end-arteries anæmic necrosis occurs in the area supplied, by the blocked vessels, and absorption of cell-débris from, or possibly microbic activity in, these areas gives rise to elevation of temperature. In the case of the spleen an infarct shows itself clinically by enlargement and tenderness of the organ, with pain on breathing, due to local peritonitis, over the surface of the spleen, thus imitating left-sided pleurisy. In the case of the kidney there may be albumin in the urine, and in rare cases red blood-corpuscles.

Embolism of the mesenteric artery is followed by intestinal obstruction. Embolism of the main arteries of the limbs gives rise to sudden pain, followed by coldness, loss of sensation, and inability to move the limb. As mitral stenosis usually occurs in young subjects whose arteries are healthy, a collateral circulation rapidly develops, and gangrene of the limbs never occurs, as it would do in older subjects, whose rigid arteries are unable to dilate, and so render establishment of an efficient collateral circulation possible. Detachment of a clot formed in the right auricle will produce pulmonary embolism; if one of the main branches of the pulmonary artery be thus occluded, sudden death follows; if a smaller branch be occluded a pulmonary apoplexy or infarct may or may not result. Pulmonary apoplexy is comparatively common in mitral stenosis, and may be brought about as just described; in many instances, however, no embolus can be found, and it appears that the localised extravasation of blood into the air vesicles is due to rupture of one of the dilated, varicose, and atheromatous branches of the pulmonary artery. However produced, it shows itself clinically by hæmoptysis; in fact, hæmoptysis in a patient with mitral stenosis is nearly always due to this cause, and hardly ever to pulmonary tuberculosis. The moist, œdematous condition of the lungs in mitral stenosis seems to prevent the settling down of tubercle bacilli, which are thus removed before they can establish themselves. After hæmoptysis in mitral stenosis pleurisy with effusion is apt to occur. It is important to examine the lungs carefully with this sequence in mind; otherwise increasing dyspnoea may be put down to the heart, on which the observer's attention is exclusively fixed.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of the journal. The lecture

ORIGINAL PAPERS.

THE PHARMACOLOGICAL ACTIONS AND THERAPEUTICAL USES OF FORMALDEHYDE.

By WILLIAM MURRELL, M.D., F.R.C.P.,

Physician to the Westminster Hospital, Lecturer on Medicine and Clinical Medicine; Examiner in the University of Aberdeen.

THIS paper deals not with the whole subject of the pharmacological action and therapeutical uses of formaldehyde, but with certain phases of it which seem for the moment to be of interest. The literature of the subject is extensive, comprising many hundreds of papers, to give a critical review of which would occupy much space.

Formaldehyde (CH_2O) was discovered by Hoffman in 1869, and during the last decade has assumed a prominent place as a therapeutic agent. It is made by the oxidation of methylic alcohol, the process employed being to pass the vapour over red-hot metal or carbon. It is a gas soluble in water, forming a colourless fluid having a peculiar odour and an exceedingly irritating taste. The 40 per cent. solution is commonly employed, and is usually spoken of as formaldehyde. It has an acid reaction due to the presence of formic and acetic acids and a specific gravity 1.070. "Formalin" is a proprietary article having the same composition.

Formaldehyde is a powerful disinfectant, more powerful than carbolic acid and only slightly less active than corrosive sublimate. It is not only a germicide, but destroys the toxins of diphtheria, tetanus and other diseases. It is extensively employed for the disinfection of rooms and for this purpose various forms of portable apparatus have been devised for manufacturing the gas on the spot. It is chiefly a surface disinfectant, and has a limited range of penetration; for example, it will not disinfect closed books. Its vapour is not injurious to fabrics, metals or woods, nor does it discharge any of the ordinary colours with the exception of violet and light red. Though destructive to micro-organisms it is innocuous to the higher forms of life, and will not kill animal parasites.

It is employed commercially as a preservative of fish, meat and other foods. In the case of milk, 1 in 25,000 or 30,000 is commonly used, but added to milk as drawn from the cow, 1 in 75,000 suffices. The quantity must of necessity be small on account of its taste. The addition to cold milk of 1 in 2,000 is readily recognised, and to milk warmed to drinking temperature, 1 in 5,000 imparts a characteristic taste.

Against the use of formaldehyde as a preservative it is urged that it renders food less capable of digestion, but the evidence on this point is far from conclusive. In investigating the subject it is necessary that attention should be paid (1) to the nature of the food; (2) to the amount of formaldehyde added; and (3) to the length of exposure to the action of the preservative. Under the first heading it may be noted that egg and serum albumin are not rendered insoluble by formaldehyde. Under the second heading it may be stated that with respect to fibrin the addition of 1 in 1,000 of formaldehyde lessens its digestive power by about 5 per cent., and of 1 in 2,000 by about 3 per cent., percentages so small as to be of no importance. Under the third heading it is found that formalisation (1 in 100,000) of beef steak for twenty-four hours has practically no retarding action on digestion. Moreover, formaldehyde in 5 per cent. solutions exerts no inhibitive action on pepsin. Tunnicliffe has shown that in healthy children 1 in 5,000 in milk and 1 in 9,000 in total food and drink exert no influence on the nitrogen or fat metabolism or on fat assimilation.

in next week's number will be by Thos. Gelston Atkins, B.A., M.D., M.Ch., Consulting Surgeon to the Cork Maternity, Surgeon to the Cork South Infirmary, and County Hospital, on "The Treatment of Hamaturia of Renal Origin."

Respecting the pharmacological action of formaldehyde comparatively little is known except that it is a local irritant. Paul Rosenberg, of Berlin, has shown that it can be detected in the blood. In his first experiment 0.48 grammes of formaldehyde were given to a rabbit weighing 1,670 grammes. At the expiration of twenty-three hours blood drawn from the carotid artery gave the reactions of the drug. In a second experiment a rabbit weighing 1,600 grammes was given 0.38 grammes at a single dose, and blood drawn from the carotid artery at the expiration of twenty-three hours gave the characteristic action. In a third experiment a rabbit weighing 1,450 grammes was given in the course of fifteen hours 0.76 grammes of formaldehyde. Eight hours after the last dose the blood was examined and was found to contain 0.775 per cent. of formaldehyde. From these experiments it is clear that free formaldehyde exists in the blood after the administration of adequate doses. That it is eliminated with the milk is shown by an experiment by the same observer. A suckling woman was given in divided doses, in less than twenty-four hours, 0.15 grammes of formaldehyde. On testing the milk, its presence was distinctly shown. It is probable that in the blood formaldehyde enters into combination with albuminous bodies, and that a portion is oxidised into formic acid. That it is eliminated by the kidneys is well-known, and Jacobson has found that 27.6 per cent. could be recovered free in the urine and 3.4 per cent. in combination, probably with ammonia. When one recalls the powerful disinfectant action of the drug, the application of this fact in the treatment of cystitis and other conditions associated with alkalinity of the urine is apparent.

Some years ago investigations were carried out by Dr. F. R. Blaxall and myself with the view of determining the action of formaldehyde on the growth of tubercle bacilli and its value clinically in the treatment of phthisis. The laboratory experiments, which lasted over a period of some months, were part of a series, having for their object the investigation of the action of certain essential oils and other volatile substances on the growth of tubercle bacilli. Incidentally it may be remarked that both oil of cinnamon and oil of peppermint had no retarding action, and were for our purpose useless; formaldehyde, on the other hand, proved most satisfactory. The apparatus used for the experiments was arranged as follows:—

A flask (A), containing a 1 in 1,000 solution of perchloride of mercury, was fitted like a wash-bottle—that is, with two pieces of glass tubing bent at right angles. The lower limb, the lower part of which was immersed in the fluid, communicated with the outside air. The shorter limb connected the flask with flask B, containing sterilised distilled water, fitted in the same way and connected by its shorter limb with a small gas washing bottle (C), which held the fluid to be experimented with. This gas-bottle again communicated with an empty sterilised glass bottle (D), and this again with a large sterilised glass jar (E), covered with an air-tight disc perforated with two holes, through which the ingress (opening at the bottom) and egress (opening at the top of the jar) tubes passed. One egress tube passed thence to a wash-bottle containing sterilised distilled water (F), similar to B, and then to a wash-bottle containing a solution of 1, in 1,000 perchloride of mercury (G). The whole of this apparatus was contained in an incubator kept at 37° C. constantly. The egress tube from flask G was connected through a perforator in the incubator with a water-pump. The water-pump being set in motion, air would enter flask A, and be freed of its organisms in passing through the mercury solution, thence pass to flask B, where any possible splittings of the mercury solution would be taken up, and thence to the gas-bottle C. Here the air would become impregnated with the volatile oil or chemical experimented with, and, passing on to the empty flask D, would leave there its superfluous moisture and enter the jar E. The current of air

would then pass through the wash-bottles F and G, and thence to the water-pump. The two flasks F and G were intended to act as a check to the outgoing of the volatile oil in the impregnated air, and also to prevent any return current of air from the water-pump. Any leakage in the apparatus could at once be seen by the cessation of bubbling in one or more of the flasks.

The apparatus was used in this way:—A dozen sterilised tubes, each of blood serum 6 per cent., glycerine agar-agar, and 6 per cent., glycerine beef-broth, were inoculated carefully from a recently-isolated culture on glycerine agar-agar of the B. tuberculosis. Two tubes each of these culture media thus inoculated were at once sealed with paraffin to serve as controls, and these tubes, with eight other tubes of each culture medium, were placed in the sterilised jar E. The remaining two tubes of each medium were capped with india-rubber caps and placed in a distant incubator, to serve as further controls. The aspirating apparatus was then started, the air bubbling through the liquid in the flasks and through the experimental fluid in the gas-bottle D, so that through the jar E circulated a current of air permeated with the vapour of the experimental fluid. The jar E at this time contained eight tubes of each medium inoculated with a pure culture of tubercle bacillus, plugged only with their sterilised cotton-wool plugs, and two tubes of each medium similarly inoculated, but hermetically sealed with paraffin. After twenty-four hours the jar was disconnected, and under a sterilised cover the cotton-wool plugs from the eight tubes of each culture medium were expeditiously removed. The lid of the jar was then carefully resealed, the apparatus connected, and the aspiration restarted, so that now the eight tubes of each medium inoculated with tubercle bacilli were fully exposed to the influence of the experimental fluid. Forty-eight hours from this time the aspiration was stopped, the jar disconnected, and one tube of each culture medium carefully withdrawn under cover, plugged with sterilised cotton-wool, capped and placed in the distant incubator to await growth. The apparatus was then reconnected and the aspiration restarted, and after another forty-eight hours, or ninety-six hours from the start, two tubes of each medium were withdrawn under the same conditions and placed in the distant incubator, and with them those controls that had been hermetically sealed in the jar.

The experiments with formaldehyde were made with a 6 per cent. solution in sterilised distilled water, an ounce of the solution being placed in the gas-bottle, so that the air bubbled freely through it. The results arrived at were as follow:—

- (a) No contaminations occurred in any of the tubes.
- (b) All the controls grew well except in the agar-agar tube sealed with paraffin in the jar; in this case the plug had been forced out and loosened and no growth occurred.
- (c) None of the tubes kept under the influence of formaldehyde vapour for forty hours, for ninety-six hours, or for ten days, showed any growth whatever.
- (d) Sub-cultures were made from several tubes of the solid media, and from all the tubes of fluid media; all of these failed, with the exception of one glycerine beef-broth tube exposed for forty-eight hours, which, re-inoculated on to blood serum, commenced, after three weeks, to grow feebly. This growth, however, did not progress, and sub-cultures made six weeks afterwards entirely failed.

To obviate the possibility of error after re-sterilisation of the apparatus, another experiment was made which, with certain modifications, was a repetition of the previous one. In this instance, no contamination occurred in the tubes. An alteration was made in this experiment. Tubes were removed from the jar after two days' exposure to the formaldehydised air, after four days, after six days, and after ten days. None of these tubes showed any growth up to six weeks from the date of inoculation, but after that date two tubes of 6 per cent. glycerine agar exposed for forty-eight hours commenced to grow; one developed

a very meagre growth, the other a fairly vigorous growth, and both were sub-cultured with success. None of the other tubes showed any signs of development, and sub-cultures from them all failed with the exception of a 6 per cent. glycerine beef-broth tube, which, after exposure for forty-eight hours, was carried on successfully.

From these experiments it is seen that even a weak solution of formaldehyde, such as 6 per cent., exerts a very marked retarding and inhibitive influence on the growth of tubercle bacilli inoculated on to favourable culture media, and that this influence prolonged over forty-eight hours entirely prevents the growth and future development of the bacilli.

In these experiments no attempt was made to estimate the amount of the volatile vapour in any given quantity of the circulating air at any given time. In the case of the formaldehyde experiments, the irritating odour of formaldehyde was most marked in the earlier stages of the aspiration, and diminished as the experiment neared conclusion. The possibility that the formaldehydised air might condense on the under surface of the disc of the jar, and fall into the open test-tubes, was obviated by inverting some of the tubes.

The clinical observations have been carried on intermittently over a period of nearly ten years, most of them in hospital practice, but some in private. Twenty cases were observed with great care, and for a long period of time, and a much larger number occurring in the ordinary routine of work have been less carefully recorded. The 40 per cent. aqueous solution was employed and it was found that patients could inhale a 2.5 solution without inconvenience. No apparatus of any kind was employed, but the drug was simply inhaled continuously from a piece of lint. No set formula was used, and the composition of the solution was varied from time to time in order to suit the exigencies of the case. Glycerine was sometimes added to prevent too rapid evaporation and it was found that oil of cinnamon rendered the vapour less irritating. The treatment was employed both in men and women, and both in early and advanced cases of tuberculous phthisis. Bacteriological examinations of the expectorations were carried out systematically, for without their aid little or no progress can be made. I give no statistics, for I attach little importance to them in a complicated investigation of this kind, but the results were most satisfactory; better, I think, than can be obtained by any other method of treatment.

It is not my intention to give details of cases, but I will mention one of many years' duration.

A man, *æt.* 46, consulted me in November, 1896. His family history was bad, several members of his family having died of phthisis, and one brother of genito-urinary tuberculosis. He had had a cough with expectoration for some months, was rapidly losing flesh, and had profuse night sweats. His evening temperature ranged from 100.5° to 102°. At the left apex in front was bronchial breathing with moist *râles*. The breathing over this region subsequently became cavernous. Specimens of the expectoration were submitted to Dr. Blaxall, who reported: "Both specimens contain tubercle bacilli. The bacilli are very slender and in clumps, and are fairly numerous. I should consider it to be an early case rather fiercely attacked, and should imagine that the prognosis was unfavourable." The patient was placed on the formaldehyde treatment, and had an inhalation almost continuously until the end of February. The expectoration was examined twice a week, but the bacilli, although fewer in number, were always present. The patient's condition speedily improved, the night sweating ceased, he gained in weight, and in March, 1897, was free from cough and expectoration. A corresponding improvement took place in the physical signs in the chest. In February, 1899, another examination of the sputum showed numerous tubercle bacilli, both isolated and in clumps, with streptococci in fair amount and a few staphylococci. The mixed infection was regarded as a favourable sign indicating

that the tubercle bacilli were being ousted. Three months later the report stated that the tubercle bacilli were all in clumps, that there was no isolated bacilli, and that they stained badly and were smaller than usual. This showed that the patient was improving under treatment. During the whole of this time he lived in England and was able to follow an active life. A couple of years later he retired from business and since then has wintered abroad. He has now passed out of my hands, but he is still alive, and continues to enjoy his ill-health. The result, considering the acute onset and the fact that the patient was but little inclined to take care of himself, may be regarded as satisfactory. The case is not put forward as one of cure, but as one in which the patient, although hampered by phthisis and other conditions not conducive to the maintenance of robust health, was for some years enabled to follow his occupation and in due course retire into private life.

I could give details of many other cases in which the formaldehyde treatment has proved of value. Some are of many years' duration, but it must be remembered that when observations are spread over a long period the patient invariably resorts, from time to time, to other modes of treatment, so that many disturbing factors are introduced, some favourable and others prejudicial. It is apt to be forgotten that, however successful a mode of treatment may be, the interval of a decade in the life of a middle-aged man means much and that at the end of that period he is not so robust, physically or mentally, as at its commencement.

I have found the vapour of formaldehyde useful in the treatment of bronchiectasis, and in a case of this description, due to the aspiration of the fang of a tooth in a dental operation, the patient was kept for many days in a small ward impregnated with this substance with manifest advantage.

Formaldehyde, from its pungent odour and taste, is by no means an easy substance to prescribe in a palatable form, and as some difference of opinion exists as to its medicinal dose I have recently made some observations on this point. To a man suffering from genito-urinary tuberculosis I gave 2½ minims of the 40 per cent. solution flavoured with spirit of chloroform and an emulsion of oil of cinnamon. This was administered in a wineglass of water and produced no inconvenience. The dose, after two days, was increased to 5, then to 7½, and finally to 10 minims. The last dose produced a certain amount of local irritation in the oesophagus, and was followed by the frequent passage of flatus. When, however, the dose was increased to 12½ minims the patient suffered from nausea and vomiting, and the administration of the drug was stopped. The same patient was given an injection into the bladder of a ¼ per cent. dilution of the 40 per cent. solution mixed with a ½ per cent. solution of cocaine. The quantity introduced was about 4 ounces, warmed to the temperature of the body. It gave rise to a considerable amount of pain and discomfort which, however, was speedily relieved by copious irrigation with boracic acid. Subsequently the injection was decreased to ¼ per cent. of the 40 per cent. solution, with the addition of a larger proportion of cocaine, but this, too, gave rise to pain. The attempt to relieve the patient of his sufferings was justifiable, for he had been treated previously, without benefit, with tuberculin, guided by frequent observations on his opsonic index.

A woman, *æt.* 28, who had been operated on for empyema, was given a single dose of 10 minims of the 40 per cent. solution, flavoured as before, immediately after a meal. There was no nausea, but in three minutes the contents of the stomach were evacuated. Another woman, suffering from bronchiectasis, was given 5 minim doses three times a day. After the first dose she complained of nausea which increased with each subsequent dose. There was no vomiting, but after the sixth dose the administration of the drug was stopped.

From these observations, it may be concluded that

the maximum medicinal dose of the 40 per cent. solution is about 10 minims.

Formaldehyde is usually said to be destitute of toxic action and it is certainly not an active poison. A man who took $\frac{1}{2}$ oz. of the 40 per cent. solution recovered; in addition to the signs of local irritation, the lips and extremities were cyanosed, no urine was passed for twenty-four hours, and the specimen first voided contained albumin but neither blood nor sugar. In the case of a man who swallowed a teaspoonful of the 40 per cent. solution, the symptoms were less severe, but he was collapsed, and no urine was passed for nineteen hours, that subsequently voided contained formic acid for two days, but neither albumin nor sugar. In another case, in which a man took a teaspoonful of the 40 per cent. solution, the symptoms were relieved by the administration of liquor ammoniac acetatis. The only recorded fatal case is that of a man who took from two to three ounces of a 4 per cent. solution, death ensuing in thirty-four hours. This would give the fatal minimum dose at somewhere between 0.66 and 2.4 drachms.

It will be well to compare this with the amount of formaldehyde contained in the dietary of a patient fed on formalised milk. In typhoid and other acute specific diseases the usual allowance is 3 pints in the twenty-four hours, that is, 480 drachms or 28,000 minims. Taking the proportion of formaldehyde at its highest, 1 in 25,000, this gives only about 1.1 minims, which is far removed from the range of toxic action. Even if the patient took ten pints of milk a day, there would still be no danger.

Formaldehyde is easily converted into a polymeric solid modification, and combines readily with starch, dextrin, sugar, menthol and all terpenes. Paraform or trioxymethylene is a colourless crystalline powder which when heated readily gives off formaldehyde. In Germany a preparation known as Formamint is largely employed and is favourably spoken of by Zwilling, Rosenberg, and others. It is a combination of formaldehyde with thymol and lactose, the former predominating. Each gramme contains 0.01 grammes of formaldehyde. I prescribe it in the form of lozenges or tablets flavoured with citric acid, and find that they are useful in pyorrhæa alveolaris and a most valuable remedy for flatulence, whether due to atonic dyspepsia or dilation of the stomach, the result of pyloric obstruction. From their local antiseptic action they have been used with benefit in tonsillitis and the sore-throat of scarlet fever and diphtheria.

Formaldehyde has a wide range of usefulness, and will be found a valued addition to our list of active remedial agents.

A NOTE UPON SOME UNUSUAL FORMS OF MIGRAINE IN CHILDREN.

By SYDNEY STEPHENSON, F.R.C.S.,

Ophthalmic Surgeon to the Kensington General Hospital, the Evelina Hospital, and the North-Eastern Hospital for Children, London.

It would be a truism to say that many, perhaps most, of the headaches of children belong to the migrainous type. That fact, of course, is known to every medical man who has much to do with children. It is, I suppose, equally well recognised that juvenile migraine offers certain peculiarities, as examples of which one need merely mention the common bilaterality of the headaches, the marked tendency to periodicity, the relative frequency of tinnitus as a sensory manifestation, and the comparative rarity of premonitory hemianopsia or teichopsia. In fact, like some other diseases, migraine, as it occurs in childhood and in later life, offers several points of contrast, two or three of which it is the purpose of the present paper to

illustrate with cases drawn from my practice. I can entertain no doubt that these forms of migraine, although perhaps uncommon, are perfectly familiar to most physicians, so that I wish to disclaim the least originality for my subsequent remarks. I do not purpose to touch upon that peculiar condition in children which has been described (somewhat unfortunately) as "hemianopsia with third nerve paralysis," the *migraine ophthalmoplégique* of Charcot, since such cases have an entirely different pathology from the vaso-motor cortical changes believed to lie at the root of ordinary migraine. (a) In all the cases examined after death of this rare and curious affection, organic changes—as tumour or tuberculous or inflammatory exudation—have been found to involve the third nerve itself at the base of the brain (see A. W. Stirling, *Archives of Ophthalmology*, July, 1905).

The particular cases to be described may be grouped under three heads as follows:—(I) migraine preceded, accompanied, or followed by temporary aphasia; (II) migraine replaced by bouts of vomiting; and (III) migraine associated with alterations of sensation or disturbances of mobility in the upper or the lower extremities.

(I.)—*Migraine preceded, accompanied, or followed by temporary aphasia.*

CASE No. 1.—George D., a neuropathic lad of 10 years, was brought to me in December, 1900, because he was backward in reading and complained of "colours" before his eyes. There was a family history of migraine preceded by hemianopsia, on his mother's side. The relative visual acuity was R. $\frac{6}{12}$; L. $\frac{6}{12}$. Under atropine, the refraction was found to be R.V. = $\frac{6}{18} + \frac{0.5}{+ 0.25 \text{ 180}^\circ}$ $\frac{6}{6}$; L.V. = $\frac{6}{12} + \frac{0.75}{+ 0.25 \text{ 180}^\circ}$ $\frac{6}{6}$. The external muscular balance was perfect ("orthophoria"). According to the history given, the lad had suffered from three attacks of migraine, the first of which occurred some two months before he was brought to me. Each bout began with an alteration in speech and numbness in the right arm, and was followed by persistent vomiting. The boy, it may be noted, was right-handed. Glasses were ordered for constant use, and it is gratifying to report that the migraine soon became a thing of the past.

CASE No. 2.—Gertrude S., æt. 12, had been subject to attacks of migraine for three years. They occurred about once a month, and were induced by excessive use of the eyes upon near objects. There was a marked history of migraine, with hemianopsia, on both sides of the family. The attacks in this child began with tinnitus and vomiting and "colours" before the eyes, and during the time they lasted (usually the entire day) the child either refused to speak at all, and became very irritable if pressed to do so, or if she attempted to speak jumbled her words together. Orthophoria. Vision two-thirds normal. Under atropine, R.V. = $\frac{6}{60} + \frac{1.5 \text{ Sph.}}{+ 0.5 \text{ Cyl. } 90^\circ}$ $\frac{6}{6}$; L.V. ditto. Constant use of glasses almost fully correcting the compound hypermetropic astigmatism that was present, reduced the number and severity of the headaches, and at the same time relieved the aphasia.

(a) Although the third is the most commonly attacked, yet other cranial nerves, as the 4th, 5th, 6th, and 7th, may be affected.

CASE No. 3.—Alan P., æt. 8, was seen in October, 1905, with the following history:—for the last two years the lad had been subject to violent headaches, occurring on the average, once in two weeks, and generally lasting twenty to twenty-four hours. The attacks terminated in an access of vomiting, and for several hours thereafter the boy could scarcely speak and tended to call common things by their wrong names. The correction by spectacles of the small amount of hypermetropic astigmatism ($+0.25$ D. Cyl. axis 180°) that existed in this patient was without effect upon the migraine.

(II.)—*Migraine replaced by bouts of vomiting.*

CASE No. 4.—Samuel H., t. 8, was brought to the Eye Department of the North-Eastern Hospital for Children on March 15, 1906, with the statement that since he was two years of age he had been subject every fortnight or so to fits of violent and prolonged vomiting. These attacks generally came on at 5 or 6 o'clock a.m., and lasted as a rule the entire day, although on occasion they had been known to persist for as long as three days. The emesis took place independently of food, and the vomited matters consisted mainly of "frothy white water." Upon close inquiry, the lad himself stated that now and then the vomiting was preceded by headache, although usually the former occurred alone. Samuel H. was one of seven children, of whom six survived. None of the others were affected in a similar way, but it is significant that two of them wore spectacles. His mother, maternal grandfather, and a maternal aunt suffered from so-called "sick-headache." Vision was equal to one-half normal. Under atropine, R.V. = $5/60$ $\frac{+5.0 \text{ Sph.}}{+1.0 \text{ Cyl. } 90^\circ}$ $5/9$; L.V.

= $5/60$ $\frac{+5.0}{+2.0}$ 90° $5/12$. The sight could not be brought above this point, even when a pin-hole diaphragm was placed in front of the optical correction. The media of the eye were clear. There was well-marked "pseudo-neuritis"—that is to say, the nasal edge of each optic disc was imperfectly defined, and could not be rendered sharp with any glass. This condition, as I have pointed out elsewhere (*Reports of the Society for the Study of Disease in Children, Vol. III., 1903, p. 342*), is common among children. Thus it was present in as many as 26 (22.80%) of 114 children whom I examined ophthalmoscopically when investigating the condition a few years ago. In the present patient it might excusably have led to an error in diagnosis unless one were familiar with this ophthalmoscopic appearance. The combination of persistent vomiting and blurred optic discs would, under the circumstances, have been suggestive of some intra-cranial mischief.

In Cases Nos. 4, 5, and 6, of which I do not purpose to give details, headaches formed an insignificant feature of the migraine, while vomiting was the symptom that led to the patients, all children between the ages of 10 and 14 years, to seek medical advice.

(III.)—*Migraine associated with alterations of sensation or disturbances of mobility in the upper or the lower extremities.*

The first case quoted in this paper furnishes an instance of alterations in sensibility under the guise of numbness in the right arm, ushering in an attack of migraine. The next case, No. 7, is an example of disturbance of mobility following

migraine. The facts are as follow:—Harriet T., æt. 17, came under my notice early in March, 1906, on account of headaches severe enough to incapacitate her temporarily from her work, that of a domestic servant. The headaches had commenced when she was six years of age, and even then were severe enough to cause her to be dismissed from school when they came on. They could be induced by reading or by straining the eyes in any way. The patient belonged to a large family (six brothers and five sisters), none of the other members of which suffered from frequent or severe headaches. Her mother, however, was affected with "sick headache." Harriet T.'s headaches began with mistiness of the sight, followed by pain in the left side of the brow, and by retching and vomiting. The headache, as a rule, lasted for two days. It was invariably followed by marked twitching in the left arm and slight twitching in the corresponding leg, lasting for about a day. No alterations in speech had been noted. The patient was affected with a considerable degree of compound hypermetropic astigmatism ($+5.0$ Sph.

$\frac{+2.0 \text{ Cyl., axis } 60^\circ}{+2.0 \text{ Cyl., axis } 60^\circ}$) the correction of which by glasses brought sight to about two-thirds normal. The constant use of suitable spectacles gave a considerable amount of relief to the hemicrania. It should be noted, finally, that this patient had suffered from rheumatic fever and chorea about a year before she fell under my notice.

Remarks.—If we accept the current views as to the causation of migraine we shall experience little difficulty in understanding the several types of the affection described in this paper. Vasomotor changes of the cerebral cortex or of the meninges of the occipital region are commonly believed to be the immediate cause of the visual manifestations of migraine. These can readily spread over to, or for that matter originate in, the cortical areas concerned with speech or hearing, or with movements of the arm and leg. Gonzalez (*Annales de Ophthalmologie, July, 1905*) has recently published two cases of migraine, each associated with aphasia only when the hemicrania was left-sided. When the pain was on the right side of the head, there was no aphasia. The first case mentioned in this paper, which was observed in a right-handed boy, was associated with aphasia and numbness in the right arm. Unfortunately, my notes do not make it quite clear whether the pain was in the left side of the head.

A similar train of reasoning would explain the sensory changes occasionally met with in migraine. With regard to vertigo as an accompaniment of migraine, that may be explained by assuming that the nerve storm has assailed the cortical centre of hearing in the temporal region. I may take this opportunity of stating that I have met with a few cases in which severe vertigo, not associated with any particular headache, or with organic disease, occurred in children, under such circumstances as to lead me to suspect that it was nothing more or less than a manifestation of migraine. I only regret that I am not in a position at this moment to give precise details of the cases.

THE King of Italy has conferred upon Mr. Guy Francis Laking, M.V.O., the Royal Order of the Crown of Italy, and the consent of his Majesty King Edward has been given to accept and wear the same.

CLINICAL RECORDS.

CARCINOMA CUTIS, WITH NOTES OF TWO CASES.*

By C. M. O'BRIEN, M.D., L.R.C.P.,

Physician to the City Hospital for Diseases of the Skin and Cancer, Dublin.

BELIEVING the subject of carcinoma cutis to be of equal interest to the surgeon and physician, I am induced to bring forward the two following cases:

CASE I.—A woman, æt. 39, married, no family, was admitted to Skin Hospital on June 4th, 1904, complaining of slight soreness of right breast with stabbing pains. Personal history.—The patient stated she always enjoyed excellent health until about a month previously, when her attention was directed to the right breast, which appeared fuller and heavier than normal, with darting pains occasionally. The pains were often relieved by pressing the breast with her hands. A fortnight before her admission to hospital she presented herself at one of the city hospitals, where the visiting surgeon and his colleagues, after examining her, declined to operate.

On admission to Skin Hospital, on June 4th, 1904, the skin over the right breast, to the extent of two square inches, including the nipple and areola, was thickened, dry, leathery, and of a darkish green colour. On manipulating, it was found adherent to the gland, but the breast moved freely over the underlying ribs, the glands in the axilla were not perceptibly enlarged. The left breast was perfectly normal. In the hope of mitigating her suffering, which was daily becoming more pronounced, she got ten minutes exposure to the X-rays four times weekly; and although the pain almost entirely subsided, nevertheless the disease continued to spread so rapidly that in a month after her admission almost the entire skin over gland was involved. A fortnight later the skin over upper surface of left breast, to the extent of a five-shilling piece, was attacked, first assuming a pale, glassy appearance, somewhat thickened and strongly suggesting scleroderma, but afterwards changing to a dark green. The gland and superficial tissues of the left breast were in the early stages quite free, later becoming involved, forming a rigid casing continuous with that of the opposite side, giving rise to laboured breathing, pallor, and very progressive weakness, the patient describing her hapless condition as if her chest were pressed in a vice. She left hospital on August 27th, after a stay of about ten weeks, the disease by this time having spread to the right axilla and skin over inferior angle of scapula, forming a complete casing for right side of chest, front and back, on auscultating over which greatly diminished breath sounds were perceptible. The heart and internal organs generally were healthy, no family history of cancer. She died in extreme agony on December 4th, 1904. There was no *post-mortem*.

CASE II.—Mr. R., æt. 53, unmarried, managing director of a large flour mill and bakery. Consulted me in January, 1904, for a patch of roughness found right nipple, which had persisted for nearly eighteen months, notwithstanding his having applied various ointments and later tincture of iodine, thinking he was suffering from ring-worm which affection he contracted as a boy. There was slight discharge, but no actual pain.

On examination in January, 1904, the right nipple, although not perceptibly retracted, was covered with branny scales, as was also the areola, the base of the nipple was slightly fissured and presented some oozing, and there was considerable pain on manipulating it. The treatment for eczema was prescribed and carried out. I next saw him early in February, but could not detect any marked change. Between February and July I saw him twice, I again saw him in October, when he

complained of its becoming itchy, and of its having bled slightly, the fissure of nipple before referred to had by this time extended to areola, the patch had increased in size, redness had become more pronounced, especially at circumference, while, towards the centre, there was oozing, with a sodden condition of epithelium. Some of the adherent scales were now removed, by forceps, and placed under microscope in a 40 per cent. solution of caustic potash with negative results. The fissures were now touched with nitrate of silver stick, while the usual remedies for eczema were further persisted in. I saw him again in January and July, 1905, there was more oozing, the eroded patch was studded here and there with bright red spots, which bled freely on being touched, the margin though well defined was not raised, the nipple was not retracted. He consulted me again last month, when the sore presented pretty much the same characteristics as those mentioned as having been present in July. Careful examination on each occasion could elicit no tumour in breast nor involvement of glands in axilla. There was no history of cancer, or psoriasis, in family. The patient never had specific disease.

CONCLUDING REMARKS.

CASE I.—*Cancer en Cuirasse*.—This case interested me because of (a) the age, which was much below the average at which recorded cases of this nature occur; (b) the non-involvement of the lymphatics, as evidenced by the absence of œdema of the upper extremities; (c) the absence of ulceration throughout; (d) the slowness with which it caused fatal results.

CASE II.—*Paget's Disease*.—My case as above recorded may admit of discussion, because the positive exclusion of chronic eczema being difficult in this, as in all such cases at an early stage. Possibly its presence in the male may lead to some increased facilities of controversy, and even excite in the minds of others opinions perhaps unfavourable to, or suspicious of, the diagnosis, even though in the literature of the affection—from 1874, when first described by Sir James Paget, down to the present—nothing can be discovered to explain why it should not occur in the breast of a male.

I have based my diagnosis on the age of patient, the short limitation of patch, with its red raw granulating appearance, coupled with the fact that for nearly two years it has failed to yield to almost every well-known remedy for eczema; whether subsequent events in its history confirm or disprove that diagnosis I am not prepared to say, but, for the sake of humanity, I shall hope for and welcome the latter.

Apròpos of this, my friend Professor Gaucher, of Paris, recently showed me a case "Maladie de Paget," under his care at the Saint Louis Hospital, which I consider a parallel one to mine, excepting perhaps that his was slightly more advanced and occurring in the female.

THE OUT-PATIENTS' ROOM.

WESTMINSTER HOSPITAL.

The Differential Diagnosis of Tabes and Peripheral Neuritis.

By PURVES STEWART, M.D., M.R.C.P.

AMONG the out-patients on February 19th were two men, both of whom complained of difficulty in walking, obscure pains in the legs, and in both patients the knee-jerks were absent. The clinical facts were as follow:—

The first patient, an insurance agent, æt. 60, complained of aching pains in the legs, of some ten years' duration; the pains were aggravated by exertion, and when the patient walked he found himself very unsteady. The previous history was unimportant; he denied venereal disease and stated that he was temperate in alcohol. On examination, his pupils and cranial nerves were normal, there was no cutaneous anæsthesia of the trunk or limbs; there was no muscu-

* Read before the Medical Section, Royal Academy of Medicine, Ireland.

lar wasting or tenderness, and beyond a slight feebleness in the gait, the motor functions were normal. There was no sphincter trouble. The supinator-jerks knee-jerks and ankle-jerks were absent.

The other patient, a labourer, æt. 44, complained of some unsteadiness of walking of about six years' duration, precipitancy of micturition and occasional shooting pains in the leg. Nine years previously he had a venereal sore which was treated for five weeks, but was not succeeded by any cutaneous rash, or sore throat. On examination, the patient's pupils, although not circular, reacted normally to light, and on accommodation; his cranial nerves were otherwise normal. There was no cutaneous anæsthesia, his gait was practically normal, he did not sway with his eyes closed and his feet together. The right supinator-jerk was present, the left absent; the knee-jerks and ankle-jerks were both absent.

These two cases presented several points of resemblance. In both of them there were pains in the legs, both complained of some unsteadiness in walking, and in both the deep reflexes were absent in the lower limbs. In one case, however, there was some sphincter trouble, whilst in the other the bladder was normal; moreover, the irregularity of the pupils in the one case suggested the probability that the venereal sore had really been syphilitic. The two most likely diseases which fell under consideration, Dr. Stewart pointed out, were tabes and peripheral neuritis, and the diagnosis between the two might be a matter of dispute; fortunately, however, the physician nowadays possesses a means of distinguishing between the two without possibility of error: this being accomplished by examination of the cerebro-spinal fluid. Normal cerebro-spinal fluid, Dr. Stewart said, even after prolonged centrifuging, contains practically no cellular elements beyond an occasional endothelial plate and perhaps one, or at most two, lymphocytes in a field of 400 diameters, but in tabes there is constantly present from the earliest stage of the disease an enormous excess of lymphocytes. In a recent series of twenty-five cases of tabes Dr. Stewart had found an average of 130 lymphocytes to the field, the lowest count being 46, and the highest over 300. In peripheral neuritis, on the other hand, the cerebro-spinal fluid is normal. Dr. Stewart therefore performed lumbar puncture on both of these patients. In the first case the fluid was normal; tabes could therefore be confidently excluded. In the second patient, on the other hand, there were no fewer than 177 lymphocytes to the field, the diagnosis of tabes was therefore established. It was no longer necessary to wait for the appearance of all the classical symptoms, such as Argyll-Robertson pupils, ataxic gait, &c., in order to diagnose tabes dorsalis, inasmuch as examination of the cerebro-spinal fluid enabled the physician to recognise the disease in its incipient stage. The prognosis in these two cases was, of course, entirely different; tabetic degeneration being from its nature incurable, whilst the peripheral neuritis, with massage, electrical treatment and the administration of strychnine, would probably recover completely.

OPERATING THEATRES.

NORTH-WEST LONDON HOSPITAL.

TWO CASES OF RETURN OF CANCER IN REMOTE PARTS AFTER A LAPSE OF YEARS.—*First Case.*—Mr. MAYO COLLIER operated on a case of obstruction of the upper part of the rectum due to malignant disease appearing five years after a posterior gastro-enterotomy for malignant disease of the pylorus. The patient, a man, æt. 48, consulted Mr. Collier some five years ago for vomiting, general discomfort after meals, and much wasting. The case was fully reported in the *Lancet*, and at the time some doubt was expressed in the annual review of the *Lancet*, as well as by the well-known authority, Mr. Moynihan, as to

the nature of the obstruction, from the fact that on examination some twelve months after operation the growth had almost entirely disappeared, and from the fact that the patient had increased in weight from nine to fourteen stone. At the original operation in 1901 Mr. Collier had the advantage of the assistance of the well-known surgeon and pathologist, Mr. Jackson Clarke, who expressed an opinion that the growth was undoubtedly malignant; the truth of this opinion and the fallacy of the criticisms as expressed in the *Lancet* and elsewhere were fully borne out by the fact that an extension of the malignant growth of the pylorus to the abdominal wall in site of the operation wound took place some eighteen months ago; the whole time, however, the short circuit has remained efficient and has fully performed its functions, and the man has enjoyed a fair measure of health and strength. The present condition dated from just before Christmas, when the patient complained of great distension and discomfort in the lower left pelvic region and great difficulty in getting the bowels open. The fact that obstruction in the upper part of the rectum was present was apparent by the swollen and markedly clear outline of the sigmoid flexure. The patient being anxious to attend to his duties as a blacksmith as long as possible, postponed the proffered offer of admission into the hospital until absolutely forced to seek relief. On admission, the patient's general condition was fair, although he was very much thinner than when at his best. The malignant growth in the wall of the epigastrium had scarcely, if anything, increased, and the amount of sickness associated with the obstructed rectum was inconsiderable, always being satisfactorily relieved by daily enemata; the abdomen was somewhat distended, tympanitic, and showed clearly the outline of the distended and active sigmoid flexure. On examination per rectum a mass as large as half a cocoa-nut could be felt in the anterior wall of the rectum high up, and extending into the left iliac fossa; the lumen of the bowel was now narrowed and admitted only the tip of the index finger. Mr. Collier said that in this case there was only one course to pursue, and that was to open the bowel above the obstruction. The question as to where the bowel should be opened was, he thought, a matter for urgent consideration; he feared that left inguinal colotomy would be associated with much difficulty, as the disease had apparently extended into the first part of the sigmoid flexure and the walls of this intestine would probably be affected for some distance. A lumbar colotomy was not a desirable procedure, for the patient would have to rely to a large extent on himself for assistance in dressing the new outlet for his evacuations. Transverse colotomy was quite put out of court by the extensive invasion of the abdominal walls in the epigastric region. A right inguinal colotomy would probably finish the patient off earlier than if no operation were performed. Mr. Collier opened the abdominal cavity on the left side by an incision parallel to the upper part of Poupert's ligament, midway between the iliac spine and the outer edge of the rectus abdominis muscle in a line with the umbilicus. On reaching the peritoneal cavity some stained fluid exuded, and the colon was at once found immediately below the incision. Mr. Collier's worst fears were realised, for the whole colon within reach was not only invaded by growth, but was held firmly within the abdominal cavity. The only course to pursue now was to extend the incision upwards and outwards to the left, and to endeavour to find a portion of healthy bowel that could be brought

out of the wound. With the able assistance of Mr. Templeton this was achieved with some considerable difficulty. The bowel was stitched to the abdominal wall in the usual manner, and the patient returned to bed. Mr. Collier said that he had no fear in stating that this was an unusual and very instructive case, not only from the length of time that the original affection of the pylorus must have existed, but from the unusual position of the secondary growth, and from the unusual fact that a re-infection had taken place in a remote part. This case, he considered, was also extremely encouraging in showing the excellent effect that prompt gastro-enterostomy has in cases of pyloric obstruction, if done sufficiently early, in apparently arresting the headlong course of the cancer growth and restoring the health and vigour of the patient for a considerable period of time. In this case, he said, the original operation had secured comparative immunity from the condition of things that pertained at the first operation. Even now if the rectum were not obstructed, the patient would have a fair prospect of enjoying a further period of health and activity.

Case 2.—Mr. Collier operated on another case which he said was to some extent on all fours with the main points of the preceding one. The patient, *æt.* 64, had presented himself at the hospital some four years ago complaining of soreness on the upper surface of the front part of the tongue; this condition had existed some eighteen months and was not abated by previous treatment. On examination, the tongue was found to present several raw patches on the left border and upper surface and two well-marked plaques were present near the median raphe; there was no history of syphilis, but the patient had complained off and on for the last few years of rheumatic pains in various parts of the body, and was of a gouty and rheumatic temperament. Mr. Collier advised that no further time should be lost, but that the anterior half of the tongue be removed. The patient would not consent to this, but agreed that the plaques should be removed so as to leave him a thoroughly useful tongue. A large oval piece was excised from the centre of the tongue well down to the muscles; this on examination was found to be commencing epithelioma. The patient was warned to keep himself well under observation by attending once a month for examination of the tongue and surroundings. Twelve months afterwards some suspicious thickening was evident in the fore part of the tongue near the tip; no glands could be felt in either submaxillary region or in the floor of the mouth. Mr. Collier again urged that the whole of the tongue should be removed, as well as the glands in both submaxillary regions. To this the patient would not consent. A less extensive operation was performed by removing the whole body of the tongue, but leaving two side flaps near the base, so that when these were brought together a small but useful stump would be left. This operation was performed, and the patient made a rapid and complete recovery. The man had been kept under observation for the last three years, and no recurrence had taken place in the tongue or neighbourhood. Some six months ago the patient sought treatment elsewhere for a crop of warts on the prepuce and glans penis; these warts, when first seen by Mr. Collier, were apparently such as one often sees as the result of want of cleanliness in hospital cases; the foreskin was studded by a number of flat, discrete patches, and the whole of the surface of the glans was red and excoriated, apparently from

the secretion from the prepuce. The free use of soap and water with the subsequent application of nitric acid to each individual wart was for a time sufficient to greatly improve matters. Healing of the prepuce took place, and the majority of the warts disappeared. Subsequent applications of nitric acid were required but it was found that successive crops of warts appeared, not only on the foreskin, but also on the glans penis and in the sulcus of the corona. No glands could be felt at this period in either groin. Mr. Collier urged that, considering the patient's age and the previous condition of his tongue, no time should be lost in removing the whole penis. The man was adverse to this procedure and was lost sight of for several weeks. On lately presenting himself again at the hospital, a condition of things was present that could leave no doubt as to the propriety of the previous advice. The glans penis, as well as the prepuce, was now a fungating mass of granulations; the body of the glans was distinctly hard, and there was a large gland in the right inguinal region. The patient now consented to operation, and Mr. Collier removed the penis close up to the pubes by the usual flap operation. The gland in the groin was also removed. Here, again, Mr. Collier said the interest of the case centred on the fact that the original malignant disease of the tongue after the second operation had become more or less quiescent, and that a recurrence had taken place in a remote organ far from the original site of the trouble, and in no lymphatic connection with the original growth. The same question, he remarked, presented itself: Is this a recurrence or a re-infection?

The Sale of Poisons.

THE Earl of Crewe's Poisons and Pharmacy Bill was issued as amended in Committee immediately before the adjournment of the House for the Easter recess. An important clause restricts the sale of sulphuric acid, nitric acid, hydrochloric acid, soluble salts of oxalic and similar poisons, without, however, limiting the class of persons by whom such poisons may be sold.

Trinity College, Dublin.

THE following candidates passed the final examination in medicine during Hilary term, 1906:—Midwifery.—Ralph S. Oldham, John Du P. Langrishe, Francis O'B. Ellison, passed on High Marks; William Hutcheson, Ernest D. Caddell, Thomas D. Graham, Thomas King Edwards, Henry D. Drennan, Michael P. Leahy, Alfred C. Elliott, Ernest C. Phelan, Reginald Holmes, Dudley F. Torrens, John Gray, Francis Casement.

Dublin Hospital Sunday Fund.

THE annual meeting in connection with the Dublin Hospital Sunday Fund was held on the 9th inst., when the reports of the Council and Committee were submitted. The former stated that collections for the fund were made on November 12th, 1905, in 274 places of worship. The "Hospital Sunday Fund Football Match," instituted by Mr. R. M. Peter, in 1878, took place on Saturday, January 6th, 1906, and yielded the sum of £27 3s. for the benefit of the Fund. The amount contributed to the Fund for 1905 was £3,765 1s. 11d. (which includes a generous donation of £100 from R. P.) being a decrease of £112 2s. 7d. as compared with 1904. The awards to the various hospitals amounted to £3,600, and were distributed as follows:—Sir Patrick Dun's £295 16s. 1d.; Royal City of Dublin, £469 0s. 6d.; Stevens', £140 14s. 10d.; Meath, £402 0s. 6d.; Mercer's, £251 17s. 3d.; Drumcondra, £45 12s. 6d.; Coombe, £95 16s. 3d.; Rotunda, £167 8s. 4d.; Royal Victoria Eye and Ear Hospital, £377 16s. 9d.; Convalescent Home (Stillorgan), £195 3s. 11d.; Cork Street, £161 17s. 7d.; Adelaide, £502 11s. 8d.; Monkstown, £139 14s. 4d.; Orthopædic, £191 19s. 5d.; National Children's £198 10s. 1d.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, MARCH 23RD, 1906.

The President, SIR ARTHUR CHANCE, P.R.C.S.I.,
in the Chair.

TREATMENT OF ACUTE PERITONITIS.

MR. EDWARD H. TAYLOR read a paper on the above. After some introductory remarks concerning certain clinical and pathological types of acute peritonitis Mr. Taylor laid emphasis upon the importance of accurate diagnosis of the starting point of the infection. He discountenanced the administration of morphia before a diagnosis had been made, owing to the way in which it masked symptoms. Mr. Taylor then discussed the principal indications for prompt surgical intervention and the points upon which reliance should be placed in arriving at a conclusion as to the necessity or advisability of operation. In connection with the operation itself, he strongly advocated general anaesthesia, but recommended that it should not be unduly pressed. Local anaesthesia might suffice if it were desired merely to evacuate an encapsuled collection of pus or establish a faecal fistula. The conditions likely to be encountered on opening the abdomen were then briefly alluded to and their significance explained. The exact means which should be employed for removing the peritoneal exudate—viz., dry mopping or flushing—were considered in detail, and their advantages as well as their drawbacks pointed out. In conclusion, he reviewed the subject of peritoneal drainage—viz., the best means for ensuring it, and the difficulties which had to be encountered. He regarded drainage of the general peritoneal cavity as practically impossible owing to the rapidity with which drains of all kinds were encapsuled. When acute peritonitis had reached an advanced stage, the abdomen being greatly distended, the extremities cold and livid, the heart's action weak, and the pulse very frequent and feeble, it was doubtful if operative measures could hold out much hope. Abstention from operation in such cases would probably afford evidence of a wise discretion. If intestinal paralysis were impending the caecum might, with advantage, be opened and drained (typhlotomy). Incision and evacuation of the small intestine (enterotomy) or drainage by one or more apertures (enterostomy) too often proved disappointing measures.

The PRESIDENT regarded the administration of morphia in peritonitis cases, as a rule, unwise; it might, however, be useful before operation. Flushing of the peritoneum tended to revive the patient and stimulate the peristaltic action of the intestine. He was inclined to sanction operative measures even in desperate cases, as they alone appeared to offer any prospect of recovery. He related the clinical history of a patient under his own care in whom recovery followed operation, although everything pointed at first to a speedily fatal issue.

MR. R. CHARLES B. MAUNSELL considered morphia before operation harmful, as it tended to cause flaccid distension of the intestines. His own practice was to mop out and dry the peritoneum with gauze, and drain in cases of diffuse (not generalised) peritonitis. He did not flush under such conditions. He described the method which he usually carried out when flushing was indicated. Two openings were necessary, one above and the other below the umbilicus in the hypogastrium.

DR. GOULDING was not strongly opposed to the use of morphia, he regarded it of enormous value in relieving pain. He was in favour of flushing as a means of cleansing the peritoneum.

VOLVULUS OF THE CAECUM TREATED BY REDUCTION AND APPENDICOSTOMY.

MR. R. CHARLES B. MAUNSELL read a paper on the above. The appendix was used as a means of fixation and drainage. Mr. Maunsell advocated closure of the appendicostomy opening by excision or invagination of the mucous lining leaving the muscular portion of the stump to cicatrise. He did not consider it necessary to formally excise the stump from the caecum. The indications for the operation were then briefly enumerated, and attention was drawn to its obvious use as a means of combating ileus in peritonitis.

The communication was discussed by Mr. Wheeler and Mr. Edward H. Taylor.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, APRIL 6TH, 1906.

The President, DR. LINDSAY STEVEN, in the Chair.

OPERATION FOR ASCITES.

DR. A. N. MCGREGOR read notes of a case, in which he had operated, for Dr. T. K. MONRO, for troublesome ascites, by stitching the omentum to the parietal layer of the peritoneum. The patient was shown at the meeting, and although it was seven months ago since the operation was done there was no ascites present. The lower border of the liver was practically in its usual position. The cause of the ascites was found, on inspection of the liver at the operation, to be cirrhosis of the liver. The symptoms generally pointed to interference with the portal circulation and back pressure. One remarkable feature of this case was that the man was strictly temperate in his habits, only taking a bottle of beer daily with his supper.

CASE OF SYRINGOMYELIA.

In the absence of Dr. T. K. MONRO, DR. JOHN FINDLAY showed a man who had for several years been suffering from that comparatively rare disease—syringomyelia. The muscles of the right hand and arm were wasted, and the anaesthetic area was pronounced over the right arm and right lateral half of chest and neck, skirting the face at the lower border of the lower jaw. Scoliosis, inequality of the pupils, ankle clonus, and wasting of the muscles of the right leg were also demonstrated.

DR. HUGH MCLAREN showed a number of sections of the cord at different levels, which exhibited the pathological appearances in a case of syringomyelia who was also a patient of Dr. T. K. MONRO.

DR. W. F. SOMERVILLE read an instructive paper on the influence of

HIGH FREQUENCY CURRENTS ON THE SURFACE TEMPERATURE OF THE BODY.

He was led to undertake this investigation from patients expressing that they felt warmer after electrical treatment. He found the surface rise of temperature greatest on the flexor side of the right forearm. With 500 M.P.'s he had got as big a rise as 9.2°F. The internal rise of temperature was never very great—a few degrees.

DR. SOMERVILLE thought this rise of temperature connected with the vaso-motor system and an increased blood supply, and considered that these changes might account for the great beneficial action brought about by the use of high frequency currents in cases of nervous exhaustion and allied diseases.

CENTRAL MIDWIVES BOARD.

MEETING HELD APRIL 10TH.

The President, DR. CHAMPNEYS, in the Chair.

THE first business of the Board on this occasion was the appointment of President and Treasurer. Dr. Champneys was re-appointed as the former, and Mr. Fordham appointed as Treasurer.

The SECRETARY then read a letter from the President and Fellows of the R.F.C.P.I., and from the University of Dublin, asking if it would be possible to have examinations there.

The PRESIDENT pointed out that both Ireland and Scotland had placed themselves outside the Act, and, on the motion of Mr. Fordham, it was agreed to send answer that the Board was not prepared to take the Act out of the area defined by Parliament.

The revision of rules was proceeded with, and letters were read expressing regret from Sir Wm. Sinclair and Mr. Ward Cousins that work had prevented their coming, but the President urged that the revised rules were already overdue, and it would be wise to discuss Sir Wm. Sinclair's motion concerning wholly illiterate candidates presenting themselves for examination.

Mr. FORDHAM suggested adding the words, "That she possess sufficient knowledge to read and take notes of cases" to the existing rule.

The PRESIDENT was of opinion with Sir Wm. Sinclair that there ought to be some sort of test. He had interviewed the head of the Education Board, but had been told there was nothing available. Certainly the candidate ought to be stopped early in, if not before, the examination.

Dr. DAKIN asked what "read the text-books" meant in the rule as it stood?

Mr. FORDHAM thought interpretation were better left to the presiding instructor.

Miss WILSON asked if any complaints had been sent in by examiners or any candidate rejected.

The SECRETARY answered, that examiners never gave grounds of rejection.

The PRESIDENT said Sir Wm. Sinclair would like to stop illiterate candidates from appearing at examinations by pointing out to them that they were hopelessly illiterate.

Miss WILSON, regardless of the fact that Sir Wm. Sinclair had given personal evidence of many such women coming under his notice, said it would be different if they had had complaints from examiners. It would not do to raise the standard too suddenly. She opposed the motion.

Dr. PARKER YOUNG argued that measures ought to be taken early. It would not be fair to take a woman's fee and then refuse to sign; but

The PRESIDENT answered that was merely a prophecy, and the words suggested by Mr. Fordham were added to the existing rule.

With regard to the laying-out of the dead by midwives, it was agreed that she must not lay out anyone she had not been attending, and a letter was read from the L.C.C. asking that any midwife who had laid out a body must "undergo adequate cleansing and disinfecting to the satisfaction of the local supervising authorities," which request was carried.

The rule relating to the administration of drugs was passed as read:—"A midwife must notify each occasion on which she is under the necessity of administering any drug other than a simple aperient; the dose, time, and cause."

The question of fee to a medical practitioner summoned by a midwife was discussed. Letters from the Privy Council and the Local Government Board stated that it was a mere matter of arrangement. There were plenty of patients able to pay who would not. In the case of the necessitous poor, the money should come out of the rates at the discretion of the local authorities.

Dr. PARKER YOUNG said he presumed the doctor had his fee for notifying puerperal fever.

Miss PAGET replied that was so, but the midwife should have one too, and that would encourage her to notify.

The PRESIDENT: The nurse has to call in the doctor and the matter is then in his hands. Suppose the midwife notifies it as puerperal fever, and the doctor says it is not. Clearly the decision and the fee are his.

The rules re "Calling in a registered medical practitioner," were slightly revised, it being agreed to add

"white leg and mania" as "emergencies," and, on a suggestion from the L.C.C., "primary and *post-partum* hæmorrhage also. The Privy Council had written saying they thought it would be better if midwives told their patients at the beginning, "that there might be a necessity of sending for the doctor at any moment."

Mr. FORDHAM objected that the poor had always a great fear of sending for the doctor, and if the fact of such a possible necessity be hinted at the beginning it would destroy confidence in nurses and result in resorting to uncertificated women.

Dr. PARKER YOUNG thought the patient ought to be told. But

Miss PAGET added that, as the necessity did not arise in more than three per cent. of the cases, she saw none for making the rule. Whereupon

The PRESIDENT arranged that answer should be sent saying the Board did not think it advisable to follow the Privy Council's suggestion.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD. FRANCE.

Paris, April 14th, 1906.

AN INTERESTING CASE OF TUBAL PREGNANCY.

PROFESSOR POZZI had a case under his care recently at the Hospital Broca, Paris, which presented somewhat unusual features; and for the report of which we are indebted to Dr. L. Montaigne. The patient was a married woman, the mother of two healthy children; her two labours had been quite normal, and she had always been regular. Two days before admission to the hospital she had, after her mid-day meal, a fainting fit, accompanied by an abundant hæmorrhage; during the next day fainting fits occurred at intervals of two hours, and on the following day, after having been treated for twenty-four hours by serum injections (500 grammes in all), she was admitted as an urgent case to the Broca Hospital, under Prof. G. Pozzi. Dr. Dartigue was immediately sent for and diagnosed tubal pregnancy (the patient acknowledged that methods of abortion had been practised) and decided on immediate laparotomy. The hysterectomy which was performed took twenty-two minutes. The uterus when removed showed all the characteristics of an extra uterine pregnancy; hypertrophy, very apparent, decidua, an evident tubal pregnancy; the left tube was open and full of blood clots. The operator said that the case under observation presented very rare features, especially with reference to diagnosis and also to the importance of immediate operation. In his opinion it proved the absolute necessity of immediate surgical intervention.

Five days after operation there had been no rise of temperature and the patient was progressing favourably.

SUICIDE OF A POLICE SURGEON.

Considerable mystery surrounds the suicide, at his residence, of Dr. Georges Bellemain, who for many years past has been the official medical attendant to the Paris Prefecture of Police. When the wife of deceased, on returning from a dinner-party, found the door of her husband's study locked, she had the door broken open, and found the dead body of her husband stretched on the floor. On the table lay a letter, which stated that the deceased had poisoned himself with cyanide of potassium. Dr. Bellemain appeared to be in the best of health and spirits when she left him, and his suicide has caused considerable sensation.

GERMANY.

Berlin, April 14th, 1906.

DRS. MORITZ, Oppenheim, and Otto Löw have a paper in Virchow's *Archiv*. Bd., 182, on

THE PATHOGENESIS OF GONORRHEAL EPIDIDYMITIS. It should be sufficiently determined by the present time that the gonococci are the sole exciters of the

disease in question, and that the vas deferens is the usual route by which the parasite passes from the urethra to the epididymis. There are two clinical facts, however, of which examples were seen that appear not to harmonise with this assumption, viz., that the inflammation frequently misses the vas deferens and attacks the epididymis first, and, secondly, that the first symptoms of epididymitis not infrequently appear immediately after infection. As the gonococci have no proper movement of their own, and as their spread over the mucous surface can only result from growth, it is difficult to understand how they can pass the long canal of the vas so quickly.

All these difficulties disappear when we bear in mind that the virus is passed on by the antiperistaltic action from the colliculus seminalis to the epididymis. Such movements were first discovered by Loeb, and they were later on studied thoroughly by Akatsu in the guinea-pig. The question now arises whether clinical observation shows these factors that easily lead to epididymitis are capable of exciting antiperistalsis in the vas deferens. The factors alluded to are all kinds of instrumental treatment of the urethra. Massage of the prostate, pollutions and coitus and bodily exertions. The authors have succeeded in exciting such antiperistaltic movements of the vesiculae seminales and the vas both by electrical and mechanical stimulation. They also satisfied themselves by careful feeling of the cord separated from its surroundings that similar antiperistaltic movements also took place in the human subject.

It now remained to show that these antiperistaltic movements were capable of carrying the micro-organism from the urethra to the epididymis. They inserted powerful cultures by means of a catheter near to the colliculus seminalis, and then, with the abdomen opened, by irritation of the hypogastric nerve excited contraction of the corresponding vas deferens. In a short time inflammation of the epididymis was actually set up, and the organism (*streptococci*) found within it.

The practical teaching of this is that in acute posterior urethritis instruments should not be made use of, that exploration of the prostate should only be made with the greatest caution, and that the patient should abstain from all sexual excitement and severe bodily exertions. In cases of unilateral epididymitis no local treatment of the posterior urethritis should be resorted to in order to avoid disease of the opposite side. In subacute and chronic gonorrhœal urethritis posterior irritating injection should not be employed.

Die Deutsche Med. Zeitung (23, 1906) reports

THREE CASES OF MERCURIAL POISONING.

The first was that of a young woman in the early stage of syphilis. At weekly intervals four injections of oleum cinereum, each containing 94 mgrms. of metallic mercury had been injected. A week after the last injection, the patient, who had excellent teeth, began with violent stomatitis, and on the day but one after a dangerous dysenteric diarrhoea set in. The extremities were cyanosed and collapse was setting in, when the disease was mastered by large doses of opium. As the dysentery improved, however, the stomatitis got worse, and the interchange of bloody diarrhoea and violent stomatitis repeated itself three times. After this, rapid recovery took place, and not only this, but the patient underwent three similar courses of injection treatment without any further trouble.

The second case was that of a young man who, in the course of five hours took five pills each containing 0.02 gr. of calomel. He had repeatedly taken a similar dose before. The following morning he had mucous stools with blood, sometimes passing almost pure blood. The attack lasted for two days, and was then relieved by opium.

Another case was that of a midwife who had disinfected her hands two days running with sublimate, according to the new regulations and subsequently suffered from all the symptoms of mercurial poisoning

(stomatitis, eczema, diarrhoea, a scarlatina-like rash, general feeling of illness and rigors). After a fortnight's interval began a period of intermittent intestinal disturbance, colic, constipation, vomiting, rapid pulse, jaundice, so that the patient, who was previously healthy, was confined to bed for weeks. As, however, the gall bladder was tender at this time, it was difficult to differentiate between this and an inflamed colon. It was held to be certain, however, that the severe symptoms were due to mercurial poisoning, whatever the latter might be.

Hartung observes that mercurial poisoning is not so rare. He has seen several cases of great severity. He was at first afraid to treat such cases with opium, fearing that that evil might follow the non-elimination of the poison. He overcame this fear, however, on reading in Kobert's "Intoxikationen" that opium eaters could bear the enormous dose of 1.8 grms. of calomel (about 27 grains) a day without any ill effects, which could only be explained on the hypothesis that the opium formed an insoluble combination with the calomel in the bowel. Since then he has always treated mercurial hæmorrhagic diarrhoea with large doses of opium, and with excellent results. The threatening symptoms were always cut short in a short time. In private practice he was accustomed to warn his patients against the appearance of toxic symptoms, and on their first appearance to provide them with tincture of opium so that they could take it if the symptoms became severe.

AUSTRIA.

Vienna, April 14th, 1906.

THE PHYSIOLOGICAL EFFECTS OF LEAD POISONING.

TELEKY showed five cases of lead poisoning at the last meeting of the Gesellschaft, and pointed out the effect produced by certain active muscles that are first acted on by the poison. He concluded that the straining of certain groups of muscles was an active factor in producing the paralysis.

Zappert remarked that this opinion was confirmed by his own observations in the cases of children who suffered from lead poisoning where the legs were first attacked and subsequently the hands and arms. The legs in these cases were the most active, while the hands and arms came next in order.

TETANUS AND ANTI-TOXIN.

Lotheissen next exhibited a man, æt. 46, whose right foot had been run over by a street-sweeping machine and badly lacerated. On the second day, as a prophylactic, he injected tetanus anti-toxin. In spite of this early treatment of the dreaded disease tetanic symptoms soon afterwards appeared. He affirmed that this was a very unusual occurrence, as the literature on the subject assured us that very few cases of this kind escaped.

HEPATIC CIRRHOSIS.

Neurath brought forward an interesting case of a child, æt. 6½, suffering from alcoholic cirrhosis of the liver from the excessive drinking of apple wine, of which it took a half to two litres a day.

The child showed symptoms of severe dyspnoea, a colossal increase of the abdomen, whose surface was knobby; enormous œdema of the abdomen, lower extremities, and scrotum. The superficial veins of the abdomen were greatly increased, and a considerable amount of fluid was present in the peritoneum. The right under lobe of the liver was the most affected, and the marginal percussion extended down to a line midway between the xiphoid and the umbilicus. The spleen was also hard and greatly increased in size.

The heart was normal, but the relative amount of urine was small and contained no albumen. The most prominent symptom was the persistent vomitus matutinus. The child slept badly and had intercurrent febrile attacks with terrifying dreams and frequent attacks of delirium.

The treatment first adopted was a free use of diaphoretics and diuretics, and a perfect abstention from all alcoholic and fermentative fluids. This treatment

seems to have had little or no effect and Neurath now proposes to operate and perform Talma's operation, which is an extraction of the liver and fixing in the abdominal wall.

SARCOMA OF THE LOWER JAW.

Spitzer presented a patient who had suffered from sarcoma of the left lower jaw. The bony structure as far forward as the canine tooth had been entirely removed and a prosthesis substituted. With this artificial arrangement, which was fixed to the upper jaw with a hinge, the patient could now speak and eat with his former ease and comfort.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

SCOTCH ASYLUM REPORTS.

CRICHTON ROYAL INSTITUTION, DUMFRIES.—The Commissioners, in their annual report, refer to the gratifyingly low rate of mortality in this institution, and point out that this is not a mere temporary condition, as is seen from the fact that the percentage of deaths, reckoned on the average numbers resident, has during the past two years been only about one-half of the Scottish asylum average, and state that there are two circumstances in the administration of this asylum which probably tend towards producing those healthy conditions of life upon which alone such a low death rate can depend. These are, first, the extensive segregation of the patients; second, the nutritious dietary which is provided for all classes of inmates. The average age at death was, for males 57, and for females 59. One old lady died at the age of 96, after 60 years' residence. She was the last of ten patients, whom Mrs. Crichton, the foundress, reserved her right to nominate during her lifetime. Three gentlemen died after 47 years' residence, and 22 died after 10 years. The average daily number resident during the year was 377 males and 429 females—total, 806.

Dr. Rutherford states that the sanatorium for consumption has been most useful during the year, and that the death rate for consumption last year has been lower than for many years. The average number who died annually during the past five years was ten; last year it was six; but whether this is due to the sanatorium, the experience of one year cannot determine.

The new reception hospitals have been recently completed, where the recently admitted, the acutely insane, and the sick of the pauper section of the inmates are now provided for in a manner which will do everything that is possible to promote the recovery of the curable and alleviate those suffering from bodily diseases.

The Commissioners state that the impression produced by their visit, considering the large-minded and liberal manner in which the institution is managed, and the unmistakable way in which patients benefit from methods of management, could not fail to be favourable.

ARGYLE AND BUTE DISTRICT LUNATIC ASYLUM, LOCHGILFHEAD.—The admissions to this asylum numbered 64, as compared with 73 in the preceding year. Dr. Cameron states that since 1898, when it attained the maximum, the admission rate has shown a tendency to decrease and the low rate of last year has been equalled on only one former occasion. The average age of the patients admitted was 42·8; last year it was 48 years. The proportion of aged persons received has been lower than usual. The percentage of recoveries, calculated on the admissions, was—for the men 47, and for the women—24·3. The total number under care and treatment during the year was 503. Twenty deaths occurred during the year—namely, 6 men and 14 women; and of these 8 were over 70 years of age. The death rate is considerably lower than that of the previous year and 2·8 below that of the District Asylums of Scotland for the same period. No death was due to either accident or suicide.

New workshops have been erected and are now in use. The old workshops are being converted into mortuary chapel, a mortuary, and a room for pathological work. This work has been entirely carried out by the patients and the artizan staff. A most laudatory feature in this asylum is the large amount of excellent work done by the patients and the artizan staff. The Commissioners in their report state that everything that was seen in the course of their visit indicated that the care of the patients is adequately and conscientiously undertaken by Dr. Cameron and his staff.

MURRAY'S ROYAL ASYLUM, PERTH.—Dr. Urquhart in his report states that during the year 44 were admitted, of whom 15 were men and 29 women. Thirty three persons were discharged—17 men and 16 women: The total number of persons under treatment was 181, and the average daily number on the Registers, 142. The average age on admission was 40·9 years, compared with 42·6 in the previous year. One patient was admitted at the age of 84. The causes of insanity as discovered on admission are stated to have been ascertained more or less precisely in every case; 23 were hereditarily predisposed to mental derangement; 9 belonged to families of neurotic tendencies, and the parents of 4 were alcoholic; 12 had been subjected to mental stress of a severe nature, but 8 of these presented such a family history as showed that they were inherently unable to withstand the anxieties under which they had succumbed. The usual list of physical diseases was noted as causative of, or complicating, the mental malady—special diseases of the heart, kidneys and digestive system. One case admitted became insane consequent upon an operation for appendicitis. The recovery rate on the number of admissions is 22·72, as compared with 45·94 last year. The percentage of deaths on the average number resident was 6·34. The amusements and occupations of the patients have been maintained as usual, and this asylum claims to have constituted a record for asylum theatricals, inasmuch as the chaplain produced a farcical comedy entitled "His Way and Hers." We regret that such chaplains are rare. The Commissioners state that the asylum was found everywhere in excellent order, comfortably heated and well ventilated, and draw special attention to the boilers, which supply steam for various purposes to the asylum, having been fitted with a patent furnace through which a steam blast can be passed. By this means the smoke issuing from the chimney stalk is reduced to a minimum, and the consumption of coal is greatly economised and coal of a cheaper class can be used with efficiency. They consider that this system is worthy of consideration by all those who are charged with the administration of public institutions.

PERTH DISTRICT ASYLUM, MURTHLY.—Dr. Bruce states that the admission rate for the year is the lowest since 1892, with the exception of 1900-1901, when there were only 80 admissions. The recovery rate is below the average and the death rate only 3 above the average for the last 4 years.

Hereditary predisposition to mental diseases was ascertained to be present in 23 of the patients admitted and 27 had suffered from previous attacks of insanity. Nine patients were admitted suffering from general paralysis of the insane, but every one of these cases had contracted the disease after leaving the country and taking to town life. The exciting cause of the mental disease in 13 cases was stated to be alcoholic excess. Out of 84 admissions, 27 were recurrent cases. Dr. Bruce observes that many of these recurrent cases recover again and again and have to be discharged; some are of the class which gravitate between the asylum, the prison and the workhouse, most undesirable patients who present undoubted symptoms of mental disease and are in some instances cases of sub-acute chronic insanity—the result of an acute attack of mental disease acquired in early life. He advocates the establishment of special wards in general hospitals for the admission of incipient cases as one worth considering from the point of view of the ratepayer

Attention is drawn by the Commissioners to the high order of the medical work of this asylum and to the scientific and original investigations so ably carried on by Dr. Bruce.

ACTION FOR SLANDER AGAINST A MEDICAL PRACTITIONER.—Sheriff Robertson has now given his decision in the action at the instance of a Fraserburgh chemist against a medical practitioner of the town. The Sheriff finds for the defender, with expenses. The facts of the "regrettable dispute," as the Sheriff in a note calls it, are, briefly, these: It seems that there is a custom in Fraserburgh that each practitioner has particular chemist with whom he chiefly deals, and who has the formulæ of any private prescriptions the medical man may use. The defender in this case ordered a prescription of his own devising to which he gave the name of Mist. Bis. Comp. The prescription was taken to be dispensed to the pursuer, who, not being the defender's particular chemist, had not the formula of the mixture, and dispensed a mixture which was acid, instead of being alkaline. As the result of this, certain telephonic messages passed between the defender and pursuer, and the former wrote a letter which the pursuer complained of as slanderous. The defender in it used such phrases as "false pretence," and complained to the inspector of police, as inspector under the Food and Drugs Act, and altogether seems to have behaved somewhat foolishly. On the other hand the pursuer alone published the letter, and so far from regretting his action in dispensing a prescription the formula of which he did not know, actually dispensed it a second time. His Lordship finds that the defender was privileged in writing the letter, and that malice cannot fairly be inferred from the terms of the letter. It seems to us highly regrettable that a personal dispute of this kind should have been dragged through the law courts. The affair was in itself unspeakably trifling, and a quarter of an hour's frank explanation at the outset would have settled such a difference between any reasonable men. It is pre-eminently the sort of quarrel which is likely to arise through a young practitioner standing too much on his own dignity, and is just one of the instances in which the advice of an older head would probably have saved the situation.

BELFAST.

BELFAST OPHTHALMIC HOSPITAL.—The annual meeting of this institution was held last week, the High Sheriff of the city, Mr. W. F. Coates, presiding. The medical staff report was read by Dr. Cecil Shaw, and gave particulars of a large amount of work. The cases in the extern department for the eye numbered 1,518; those in the ear and throat department 695; and the intern patients 122. The total number of visits paid by patients was 7,280. A sum of £50, asked for in last year's staff report, to complete the furnishing of the operation theatre, had been given by Mr. J. Milne Barbour, and a lady had handed to Dr. Walton Browne another £50 for the further equipment of the theatre with new instruments.

THE CONSUMPTION PROBLEM IN BELFAST.—At a late meeting of the Corporation, the Chairman of the Public Health Committee said that his committee would welcome any suggestion for lessening the death-rate or improving the health of the city. The invitation has been accepted by Professor Byers, who deals with the whole subject in an article of four columns in one of the daily papers. He has obtained figures from the Registrar-General showing the annual death-rate per 1,000 from phthisis in Dublin, Belfast, and Cork for the past twelve years. These figures are 3.6 in Dublin City, 3.3 in Belfast, and 3.9 in Cork, and show no marked change during the twelve years in any one of the cities. After explaining the meaning of the figures, Professor Byers takes as his text the circular issued by the Local Government Board for Scotland on March 10th, 1906, and shows how the excellent suggestions contained in it might be applied to Belfast. His final suggestions are: (1) A special consumption sub-committee of the Public Health Committee, with power to co-opt additional members.

(2) A dispensary for phthisis "at the head of which should be a young capable medical man who would throw his whole energies into the work." (3) The compulsory notification of phthisis. (4) The co-relation of the hospitals which accept consumptive patients, so that the most may be made of the provision they afford.

LETTERS TO THE EDITOR.

THE NORMYL TREATMENT FOR ALCOHOLISM AND THE DRUG HABIT.

SIR.—It can only be lay readers of your paper who can need telling that alcoholism is not a simple condition always due to one and the same cause; that the cases vary widely, and that their causation is extremely complex, being made up of various distinct physical, moral, and mental factors. Anyone with a sufficient knowledge—knowledge easily acquired by a cultivated intellect—of the pathology and psychology of the drunkard, must recognise that cure by a drug of the habitual excessive use of alcohol would approach the miraculous, something like the casting out of a demon of the olden days. The discoverer of such a remedy would rank among the greatest benefactors of mankind—with Jenner, Pasteur, and Lister. Wealth and fame would surely be his. All he would need to do would be to demonstrate the quality of his remedies before a competent scientific tribunal. It would be easy to name many such tribunals. I would suggest the Royal Society, or the College of Physicians, as a choice for the promoters of the Normyl treatment. The inventor of the Normyl treatment not only undertakes to cure alcoholism; he, so to say, throws into the bargain a cure for "the drug habit" as well, thus making his miracle doubly miraculous. It is not necessary to question the inventor's good faith or to doubt his confidence in the efficacy of his method. Such a belief would form only one more instance among scores of similar illusions in the history of medicine. The wonderful fact is that not only the Editor of *Punch*, who from his position must necessarily be a consummate man of the world, but a whole string of noblemen, theological dignitaries and public men should be easily found at this period of the twentieth century to give their support to a theory which can have not much more solid foundation than the belief in witchcraft or the evil eye. There does not seem to be a single man of science among them. They seem to represent not the cultivated classes from which they are drawn, but rather the uneducated mass of the public which unfortunately scorns, distrusts, or hates science and prefers often to subscribe to a belief which is evidently impossible, or even to accept it the more eagerly because it is impossible. It must surely be rare to find in such a connection a string of names of such distinction as composes the committee of the Normyl Association. I trust you will immortalise them in your columns. They are as follow:—

Chairman—Mr. Cecil M. Chapman (Metropolitan Magistrate.)

The Primate of Ireland. The Bishop of Chichester.

The Bishop of Southwark. Lord Armstrong.

Sir Arthur Wilson, K.C.I.E. Canon Scott Holland.

Mr. Stephen Simeon. Mr. Arthur W. Bartlett.

Hon. Sec.—Rev. Hugh B. Chapman.

Hon. Treas.—Mr. Owen Seaman.

I am, sir, yours truly,

HENRY SEWILL.

Cavendish Square, April 11th, 1906.

[It would be of interest to learn how many of the above persons have given their names through personal pressure, knowing little or nothing of the matter.—Ed.]

DR. E. SYMES THOMPSON, F.R.C.P., Gresham Professor of Medicine, will deliver a course of lectures on "The Nervous System" on April 24th, 25th, 26th and 27th, at six o'clock each day, at Gresham College, Basinghall Street, London, E.C. This course is open to the public, and will be illustrated by diagrams.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons in Ireland.

A MEETING of Fellows of the College will be held on Tuesday, May 1st, at 4.30 p.m., pursuant to the provisions of the Supplemental Charter, to witness the election of the following examiners:—Court "A."—For examinations under the management of the Conjoint Committee:—Two Examiners in Anatomy, to examine in Surgery when directed; four Examiners in Surgery, to examine in Anatomy when directed; one Examiner in Physiology and Histology; one Examiner in Pathology and Bacteriology; one Examiner in Midwifery and Gynæcology; one Examiner in Biology; two Examiners in Ophthalmology; one Examiner in Sanitary Law and Vital Statistics; one Examiner in Engineering and Architecture; one Examiner in Languages; one Examiner in Mathematics, Physics, Dictation, and English Essay; one Examiner in Dutch.

Court "B."—For examinations conducted by the College, and not under the management of the Conjoint Committee, viz.:—Two Examiners in Anatomy, to examine in Surgery when directed; four Examiners in Surgery, to examine in Anatomy when directed; two Examiners in Physiology and Histology; two Examiners in Pathology and Bacteriology; one Examiner in Midwifery and Gynæcology; two Examiners in Chemistry and Physics; two Examiners in Dental Surgery and Pathology; two Examiners in Mechanical Dentistry. "Graduates of any University which may be from time to time recognised by the College shall be eligible for election as Examiners in the subjects of General Education. All the other Examiners shall be Fellows or Licentiates of the College, or Professors or Lecturers in any School of Medicine recognised by the College."

"Examiners permanently residing more than one hundred miles from Dublin shall receive (in addition to their examination fees) first-class return railway fare for each occasion on which they are summoned to Dublin to conduct examinations in connection with this College."

Candidates are requested to clearly indicate whether they seek election on Court "A" or Court "B," or on both. In the latter event, they are advised to send separate applications.

Candidates are requested to lodge their applications in writing with the Registrar, at the College, on or before Tuesday, April 24th, at 10 a.m.

International Medical Congress at Lisbon.

THE Booth liner "Ambrose," left the Mersey on Wednesday evening with a large complement of passengers for the International Medical Congress at Lisbon. This steamship company have perfected arrangements for combined sea and land tours, and are now able to frank the passengers right through Portugal, by road or rail, and on *via* Badajos to Seville, Granada, and other places in the South of Spain, and Madrid, giving the option of return from Gibraltar by a P. and O. liner or from Lisbon by one of their own homeward South American mail boats. The company some time ago secured three floors at the most modern hotel at Lisbon, so as to ensure its passengers attending the Congress being comfortably provided for.

The West African Medical Staff.

In the House of Commons on Wednesday last, Mr. Churchill informed Mr. Nolan that coloured medical men of African origin or descent are ineligible for the West African Medical Staff, but are eligible for certain other public appointments in the Gold Coast, Sierra Leone, and Lagos. The West African Medical Staff is constituted principally for the purpose of safeguarding the health of the European officials of the Colonial governments; and West African native medical officers would not, as a rule, command the confidence of the Europeans.

Giebler v. Manning.

THIS was a case stated by a metropolitan magistrate on a summons taken out by the respondent, Manning, a sanitary inspector, on behalf of the Fulham Borough Council, against the appellant, Frederick Giebler, under the Public Health (London) Act, 1891, section 47 (2), for having on his premises 5lb. of meat which was seized by the respondent as being unsound and ordered by the magistrate to be destroyed. It appeared on the face of the summons, and was stated in the case to be the fact, that the information was laid by, and the summons issued to the respondent, expressly on behalf of the Borough Council. The respondent, before applying for the summons, did not report the facts to the Borough Council or to any committee appointed by them. He had never received any express authority by resolution or in writing, general or special, from the Council or any such committee authorising him to make complaints or take proceedings on their behalf. It was contended on behalf of the appellant that by section 107 (3) of the Act it was necessary that the inspector should report to the sanitary authority, and that they should authorise their inspector to apply for a summons and act as prosecutor against the alleged offender. No such report was made, nor did the Borough Council or any committee expressly direct or authorise the respondent to make the complaint and take the proceedings. The magistrate was of opinion that the reports required by section 107 (3) were confined to (a) nuisances discovered by the inspectors themselves under section 1 and other sections; (b) inquiries by them into complaints which were made as to nuisances and offences against the statute and against the statutory by-laws by private individuals under (amongst others) section 3 and 21, and as stated in evidence at the hearing these two classes of reports were always made, and as a fact consequent process was always applied for by the Council's solicitor. The offence in the present instance did not appear to fall into either class. But even if it did, the language of section 107 (3), "subject to the direction of the sanitary authority or of a committee thereof," was, in the magistrate's opinion, capable at least of meaning such direction as it might choose to give, but, however this might be, there was nothing in section 107 (3) or as regards committees in section 99 (4) compelling the authority to give directions in any particular form or manner, and, if so, he thought that the course of business adopted by the Council and committees might well justify the action of the respondent as resting on an implied direction and authority or on ratification. The magistrate accordingly convicted the appellant. Mr. Clarke Hall, for the appellant, submitted that section 107 (3) made it a condition precedent that the inspector prosecuting should have the express authority of the sanitary authority. He cited "Isle of Wight Ferry Co. v. Ryde Commissioners" (25 J.P., 254). The fact that the summons was taken out on behalf of the sanitary authority was important as regards liability for costs. Mr. Danckwerts, K.C. (Mr. W. J. Jeeves with him), for the respondent, argued that any body could take proceedings under section 47 (2), and the words, "on behalf of the Fulham Borough Council," in the summons were quite immaterial. The Lord Chief Justice, in giving judgment, said that the appeal must fail, as the case was practically covered by authority. The really important question was whether an individual could take proceedings under section 47 (2). The other learned Judges agreed, and the appeal was accordingly dismissed, but without costs.

DR. PURVES STEWART, assistant physician to the Westminster Hospital, has been appointed Physician to the National Orthopaedic Hospital.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT LITERATURE OF PHYSIOLOGY AND PATHOLOGY.

The Pathogenesis of Malignant Tumour.—The *Deutsche Medizinische Wochenschrift* of March 22nd contains a synopsis of an important communication made by Prof. Ehrlich on the subject of the pathogenesis of malignant tumours. The material used by Prof. Ehrlich and his collaborators consisted of 230 spontaneous tumours occurring in mice, which were, with a few exceptions, of an epithelial character. Of these, 94 were successfully transmitted to other animals, but only 11 could be successfully transplanted from one animal to another *ad libitum*. In these cases there appeared an extraordinary increase in the energy of proliferation, which rendered full experimental study of them possible. By artificial mixture of carcinoma and sarcoma, genuine mixed tumours were produced which, after two generations, were completely freed from carcinoma, and became pure sarcomata. This elimination was accelerated by heating the inoculation material to a suitable temperature. An intraperitoneal chondroma, occurring spontaneously in a mouse, produced, on subcutaneous inoculation, huge hæmorrhagic growths, while intraperitoneal inoculation led only to the formation of small free bodies, resembling the corpora oryzoidæ found in men.

The first result of these experiments is to show that the infectivity of primary tumours in mice is very slight, the successful inoculations constituting only $\frac{1}{4}$ per cent. of the whole number. Hence the normal organism of the mouse must contain a mechanism which hinders the growth of the developed tumour cell. Prof. Ehrlich considers that we have to make a sharp distinction between the original carcinomatous transformation of the cell and the further growth of this modified cell into a tumour. In transplantation the first moment is excluded, the developed cancer cell being used in the material for inoculation. The large proportion of negative results indicates the important part played by the resistance of the organism to tumour formation.

In general, tumour cells can only be successfully transplanted from a given animal to one of a species so closely related to it that the two can breed together. If, however, highly virulent mouse tumours be transplanted into rats, in the first six to eight days a definite tumour forms. After eight days a degeneration begins which soon leads to complete absorption. If this tumour in the rat be transferred, at the most active period of its growth, to another rat, it fails to grow, while, if transferred back to a mouse, it develops into a typical tumour. This "zig-zag" inoculation from mouse to rat and from rat to mouse can be repeated *ad libitum*, the tumour retaining its power of growth unaltered. The hypothesis which best explains this phenomenon is that the tumour cell requires for its growth a certain substance which is only present in the organism of the mouse; when the quantity of this material which has been transferred into the rat in the first inoculation is exhausted, a second inoculation into a mouse is required in order that the power of growth may be kept up. The natural immunity of the rat depends then, on the absence of this indispensable substance, and may be called an "atreptic" immunity.

In mice, if a successfully inoculated animal be again inoculated on the other side, the result is generally negative, which Prof. Ehrlich explains by assuming that the material necessary for tumour growth has been so completely exhausted by the original tumour, that there is not enough left to enable the second tumour to grow. The facts which have been determined with regard to the active immunisation of

mice against carcinoma are as follows:—The inoculation of mice with the above-mentioned hæmorrhagic tumours, which were not malignant, nor capable of growth by transplantation, resulted in the production of a considerable degree of immunity against highly virulent growths. Still more favourable results were obtained in the case of mice which had been unsuccessfully inoculated with highly virulent material. These animals were found to be immune to subsequent inoculations with any tumour material, no matter how virulent. Prof. Ehrlich attaches special importance to the fact that this immunity is not specific, but holds for the different forms of sarcoma and carcinoma. Investigations which have not yet been concluded, go to show that the animals which are immune to carcinoma and sarcoma are also immune to chondroma. O'S.

Precipitin of Snake Antivenom and Antisera.—Hunter (*Journal of Physiology*, December 19th, 1905) gives the results of experiments regarding the precipitating properties of antisera and antivenom of the cobra and daboia. With rabbits as the animals employed, he arrives at the following conclusions:—(1) Specific precipitin are produced by the injection of snake venoms, and these precipitin have no action on snake sera. Lamb had already discovered precipitin in the case of cobra venom, but regarded them as non-specific; (2) specific precipitin are also produced by the injection of snake sera, but these precipitin have a positive action on the corresponding venoms; (3) there is no constant relation between the precipitating and the antitoxic power of an anti-venom, nor between the quantity of toxic bodies and of precipitable bodies in a venom. The toxins are therefore not the precipitin-producing bodies. R.

Recent Literature of Endothelioma.—Carless (*Practitioner*, February, 1906), summarises in a somewhat haphazard fashion the more recent reports on endothelioma. (1) *Endothelioma of the salivary glands.* The salivary region is the site of many tumours of a complicated nature, of which the so-called "parotid tumour" is the best known. While there has long been discussion as to the correct pathological placing of this tumour, opinion is coming more and more to agreement that it is an endothelioma. On this theory, the cartilage which is so often present, is to be explained as a hyaline degeneration of the cells and stroma of the growth. The cells are usually arranged in well-defined columns and masses, and in some of the columns a lumen is present, the cells nearest it being flat, while those outside are spheroidal or polyhedral. It is impossible to decide whether, if these tumours be endotheliomata, the cells originate in the walls of blood or lymph vessels. (2) *Endothelioma of the testis.* Krompecher believes that endothelioma is the most common form of malignant disease of the testicles. It presents great varieties in histology, the two main types being the *alveolar* and the *diffuse*. The latter is probably what has been described by some writers as "lymph sarcoma testis," and by others, mostly French, as "lymphadenomata." The former is the most common tumour of the testicle, and has often been described as a carcinoma. In addition, tumours of the testicle are sometimes met with containing great nucleated protoplasmic masses, resembling those met with in chorion-epithelioma. (3) *Endothelioma (or perithelioma) of bone.* Histologically, these tumours conform generally to one of two types—(1) vascular tumours with alveoli filled with cells of varying character (2) gland-like structures, the alveoli of which are lined with one or more rows of cells of epithelial type.

These two forms are not infrequently conjoined in the same growth. The tumours vary greatly in vascularity, and are subject to mucoid, hyaline, and colloid regenerations.

The Importance of the Colon.—Monier-Williams (*Brit. Med. Journ.* April 7, 1906) recounts the history of a case from which we may learn something of the importance of the normal functions of the colon. For several years the patient had suffered from colitis, and in 1900 it was decided to make an artificial anus in the ascending colon. Some eighteen months after the operation the patient again became emaciated, and began to lose weight rapidly, so much so that his position became one of grave danger. It seemed reasonable to suppose that the cause of his retrogression was the failure to absorb sufficient water. To remedy this, injections of saline fluid, and later of distilled water, were made into the large intestine. The results were most satisfactory, and although the injections had to be discontinued, owing to the occurrence of severe attacks of purpura hæmorrhagica, nutrition was markedly improved. Notwithstanding the hæmorrhages, the patient improved steadily in health, and continued to increase in weight week by week. Later on, as the intestinal injections were inevitably followed by attacks of purpura, hypodermic injections of saline fluid were substituted. The effects both as regards nutrition and the occurrence of purpura, were the same. Finally, a way out of the difficulty was discovered. By blocking the artificial anus throughout each night the intestinal contents were for several hours of the twenty-four directed into the great intestine. The colon was thus given a chance of absorbing sufficient moisture. This plan was adopted nearly three years ago, and the patient has remained in excellent health during that time. Monier-Williams concludes that absorption of water from the colon is a necessary part of nutrition.

The Mechanism of Protection of Intestinal Worms.—Hamill (*Journ. of Physiology*, February 5th, 1906), details some experiments bearing on the mode by which intestinal worms protect themselves against the action of the digestive juices. Weinland, who was the first to undertake investigations of the sort on the supposition of the presence of an anti-ferment in the body of the worm, came to the conclusion that the protection of the worm against digestion was in the main due to its power of secreting an anti-trypsin. On the other hand, Dastre and Stessano, in the case of *Ascaris*, satisfied themselves of the presence of an antikinase. Like the latter observers, Hamill confined his work to *Ascaris*, of which he obtained a supply from the intestinal tracts of horses. An extract was made by grinding the worms with sand, and extracting with chloroform water. It was proved by a series of experiments that when varying quantities of this extract were added to a fixed quantity of trypsin, the digestive power of the latter as exerted on gelatine varied inversely with the quantity of extract added. The trypsin used was proved to be free of enterokinase. A series of experiments was next conducted to decide whether worm extract, in addition to its antitryptic qualities, might not also possess antikinasic properties. On the one hand, worm extract was mixed with enterokinase, and after four hours, pancreatic juice was added; on the other, worm extract was mixed with pancreatic juice, and after four hours enterokinase added. The digestive powers in the two cases were equal, showing that the worm extract exerted no powers prior to the formation of trypsin. Having thus established the relation of the antibody to trypsin and enterokinase, Hamill proceeded to investigate other qualities of the antibody. His conclusions are—(1) The antibody in the tissue juices of intestinal worms is antitryptic in its action, and not antikinasic; (2) the antibody, in neutral or acid extracts, is uninjured by boiling; in even the mostly faintly alkaline extracts, its action is immediately destroyed by boiling; (3) the antibody is soluble in weak alcohol, but is precipitated when the concentration is increased to 85 per cent. The pre-

cipitate dissolves easily in water, and diffuses readily through colloid membranes.

Ovarian Tumours and Malignancy.—Norris (*Amer. Journ. of Obstetrics*, January, 1906) discusses, with reference to the literature, the nature of ovarian tumours, paying particular attention to the question of malignancy. The frequency with which malignant disease of the ovaries occurs is stated very variously by different operators. Thus, to mention only a few, Kelly finds 8 per cent. of all ovarian tumours malignant, Olshausen 15 per cent., Schroeder, 16 per cent., Freund 21 per cent., and Leopold 23 per cent. Of Norris's 63 cases operated on since 1899, ten proved to be malignant disease, giving a percentage of 15.8; in this series, parovarian as well as ovarian tumours are included. Norris insists strongly on a thorough microscopic examination of all ovarian tumours, since in few, if any of his cases, was there anything in the gross appearance suggesting malignancy. In many cases, indeed the cancerous nature of the tumour would have been undetected unless several sections from different parts—in some cases eleven or twelve—had been made. Of a complete series of 16 malignant tumours of the ovary examined by Norris, 6 were bilateral, 4 being bilateral carcinoma, and 2 carcinoma of one side and multilocular cyst of the other. Norris calls attention to the fact that he encountered no case of sarcoma, although Pick had reported 12 out of 26 cases of malignant disease of the ovary as sarcoma. The term "sarcoma" of the ovary is, however, one which requires more exact definition.

Hæmatoma of the Ovary.—Savage (*Brit. Gynaecological Journ.*, February, 1906) contributes a careful study of the pathology of hæmatoma of the ovary, based on seven cases. The characteristic change due to this condition is the conversion of the ovary into a firm shell of œdematous or hæmorrhagic tissue, enclosing a cyst of viscid, chocolate-coloured blood; adhesions to neighbouring parts are always present, most marked where the cyst-wall is thinnest; the Fallopian tubes rarely show any gross change. Savage thinks hæmatomata of the ovary may be grouped into two classes—(1) Hæmatomata of the Graafian follicle, (2) Hæmatomata of the corpus luteum. In the first group the membrana granulosa is represented, and the process is a multiple cyst formation. The probable cause of this change is an increased amount of blood in the ovary, giving rise to premature ripening of Graafian follicles; into the follicles blood is poured, and the cysts coalesce. Cases of the second group are due to an excessive exudation of blood into the retrogressing corpus luteum. Savage finds no reason for regarding hæmatoma of the ovary as in any way associated with fibroma of the uterus.

Hepatic Cysts.—Dr. Sharp records (*South African Med. Record*, Feb. 25th, 1906) a case of solitary cyst of the liver occurring in a boy, æt. 7. During convalescence from an attack of measles a prominence in the upper part of the abdomen was noticed, which gradually enlarged and was found on examination to be tense and fluctuating. Operation was decided upon, and a large cyst was found growing in the left lobe of the liver, bulging forwards beyond the hepatic margin. It was bounded by a very thin translucent cyst wall, and contained over three quarts of bright yellow fluid. Recovery took place and no recurrence of the cyst was noted. Dr. Sharp points out the rarity of this variety of cyst, and calls attention to the fact that it has not, previous to this, been found in males.

NOTE.—A summary will appear each week in the following sequence:—

- (2) "Recent Surgical Literature."
- (3) "Recent Gynaecological and Obstetrical Literature."
- (4) "The Recent Literature of Physiology, and Pathology."

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CHARGE AGAINST MEDICAL PRACTITIONERS.

To a certain class of mind nothing appears to give greater pleasure than an attack upon the medical profession. Of this tendency we may presume Mr. Vivian possesses a more than usually virulent share. In the debate on the second reading of the Prevention of Corruption Bill in the Commons, on April 3, he alleged that a certain number of medical men received commissions on patients' coffins. It is curious that a man should go out of his way to malign a noble and self-sacrificing profession in that manner. We venture to say that there is no class of society, even including politicians, to which set Mr. Vivian belongs, that attains the general level of high and virtuous thinking and living which governs the medical community.

STUDENT (Westminster).—You will find the Edinburgh Stereoscopic Atlas of Anatomy (F. C. and S. E. Jack) a most useful aid in reading anatomy. It will probably be obtainable in your school library.

BRISTOLIENSIS.—Unfortunately we know of no means of stopping the irregular practice of a prescribing chemist. A strong combination of medical men in a district, by marking the offenders, might do a great deal to check the offender.

Ms. J. S. (Leeds).—The season on the Riviera usually ends with April, as the weather after this month becomes uncomfortably hot. We think, however, your patient would do well at Grasse, which is 2,000 feet above the sea level of Cannes and Nice, and in a beautifully-wooded district. The weather at Grasse is charming during May and June, and we have known convalescents to quickly recover their health in the pure air at this season. The best and most comfortable hotel there is the Grand Hotel, and there is a frequent train service from the railway station at Cannes to the plateau at Grasse, occupying about twenty minutes in the ascent.

F.R.C.P. (Midlands).—The best apparatus for gastrodia-phany is that devised by Einhorn. It consists essentially of an electric lamp carried on the end of a somewhat stiff bougie. Although the method is technical, costly, and troublesome, it yields results that can as a rule be attained by far simpler means.

A REMEDY FOR NIGHT-SQUALLS.

"DOCTOR," said a patient, "I'm a victim of insomnia. I can't sleep if there's the least noise, such as a cat on the back fence, for instance."

"This powder will be effective," replied the physician, after compounding a prescription.

"When do I take it, doctor?"

"You don't take it. You give it to the cat in a little milk."—*Exchange.*

Mr. CLEMENT H. S.—Your communication was unavoidably held over at press.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, APRIL 18th.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover Square, W.).—8 p.m. Exhibition of Lantern Slides of Plant Structure prepared by Mr. A. Flatters.

FRIDAY, APRIL 20th.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos Street, Cavendish Square, W.).—5.30 p.m. Clinical Cases will be shown by Dr. T. B. Whipple, Dr. W. O. Chapman, Mr. S. H. Wareham, and others. Papers:—Dr. J. McCaw (Belfast): Chloroma in a Young Subject.—Mr. R. Campbell (Belfast): The Treatment of Hernia in Children, with an Analysis of 300 Cases of Operation for Radical Cure.

EPIDEMIOLOGICAL SOCIETY (11, Chandos Street, Cavendish Square, W.).—8.30 p.m. Paper:—Dr. B. Farrar: The Infectivity of Cerebro-spinal Fever.

MONDAY, APRIL 23rd.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover Square, W.).—8 p.m. Casual communications: (1) Mr. W. H. Dolamore, M.R.C.S., L.R.C.P., L.D.S.: Two Cysts; ? Dentigerous. (2) Mr. J. G. Turner, F.R.C.S., L.D.S.: Effects of Abscesses arising from Temporary Teeth. (3) Mr. E. J. M. Phillips, M.R.C.S., L.R.C.P., L.D.S.: (i.) Hypertrophy of the Gums; (ii.) Dentigerous Cyst. (4) Mr. N. G. Bennett, M.A., M.B., L.D.S.: Teeth Devoid of Enamel. (5) Mr. W. J. May, L.R.C.P., M.R.C.S., L.D.S.: Absorbed Roots. (6) Mr. W. S. Nowell, M.A., L.R.C.P., M.R.C.S., L.D.S.: Models showing Delayed Eruption of Temporary Teeth following Rickets.

Vacancies.

Surrey County Asylum, Brookwood, near Woking.—Junior Assistant Medical Officer. Salary £120 per annum, with board, lodging, laundry, and attendance. Applications to the Medical Superintendent.

Essex and Colchester General Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and residence. Applications to Alfred C. Buck, Secretary, The Hospital, Colchester.

Wallasey Dispensary and Victoria Central Hospital, Liscard.—House Surgeon. Salary £100 with apartments, board, and service. Applications to Mr. E. Russell Taylor, Kingscourt Liscard, Cheshire.

University of Birmingham.—Assistant Lecturer on Pathology and Bacteriology. Salary £250 per annum. Applications to Geo. H. Morley, Secretary.

Inverness District Asylum.—Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

East Sussex County Asylum, Hellingly.—Second Assistant Medical Officer. Salary £200 per annum, with board, furnished apartments, and washing. Applications to the Medical Superintendent.

City of Liverpool.—Infectious diseases Hospital, Fazakerley.—Assistant Resident Medical Officer. Salary £120 per annum, together with board, washing, and lodging at the hospital. Applications to the Chairman of the Port Sanitary and Hospitals Committee, Municipal Offices, Liverpool.

Cornwall County Asylum, Bodmin.—Third Assistant Medical Officer. Salary £135 per annum, with board, furnished apartments, washing, etc. Applications to Medical Superintendent.

Gartloch Asylum, Gartcosh.—Assistant Medical Officer. Salary £125 per annum, with board and lodging. Applications to the Medical Superintendent.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Resident Medical Officer. Salary £100 per annum, with board, apartments, washing, and railway contract. Applications to C. W. Hunt, Secretary, Hardman Street, Deansgate, Manchester.

Royal National Orthopedic Hospital, 234, Great Portland Street, W.—Resident House Surgeon. Salary £200 per annum, with rooms. Applications to the Secretary.

Liverpool Infirmary for Children.—House Surgeon. Salary £100 per annum, with board and lodging. Applications to Arnold J. Cleaver, Government Buildings, Liverpool.

Holloway Sanatorium, St. Ann's Heath, Virginia Water, Surrey.—Junior Assistant Medical Officer. Salary £175 per annum, with board, lodging, washing, etc. Applications to Dr. W. D. Moore, Medical Superintendent.

London County Asylum, Colney Hatch, New Southgate, N.—Third Assistant Medical Officer. Salary £180 per annum, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk of the Asylums Committee, Asylums Committee Office, 6, Waterloo Place, S.W.

Cork Branch of the Irish Drapers' Association.—Medical Officer. Emolument, duties, etc., on application to the Hon. Sec. (see advt.).

National Maternity Hospital, Dublin.—Extern Assistant Physician. Salary £50 per annum. Applications to Secretary, Holles Street (see advt.).

Appointments.

HAY, JOHN, M.D., Ch.B.Vict., Honorary Physician to the Hospital for Consumption and Diseases of the Chest, Liverpool.

HODGSON, STANLEY, M.D., B.S.Lond., M.R.C.S.Eng., Medical Officer to the South Salford Division of Manchester.

LEGG, T. F., F.R.C.S.Eng., Assistant Surgeon to the Italian Hospital, London.

MACLAREN, WILLIAM MACLAREN, L.R.C.P. and S.Edin., L.F.P.S.Glasg., House Surgeon at the Royal Cornwall Infirmary, Truro.

PRICE, DAVID THOMAS, M.B.Lond., Medical Officer for the Castle Cary District, by the Wincanton (Somerset) Board of Guardians.

TONKING, JOHN HERBERT, M.B.Lond., M.R.C.S., L.R.C.P., Public Vaccinator for Camborne (Cornwall).

Births.

BENTLEY.—On April 6th, at Hrowth, Mitcham, the wife of Harold Bentley, M.R.C.S., L.R.C.P., of a son.

STEPHENS.—On April 11th, at Seaforth House, Hoylake, Cheshire, the wife of J. W. W. Stephens, M.D. Cantab., of a son.

WARD.—On April 6th, at Milverton, Brighton Road, Sutton, Surrey, the wife of Richard Robert Ward, L.D.S., R.C.S.Eng., of a son.

Marriages.

COTTER-MUSSON.—On April 7th, at St. Peter's Church, Fulham, George Edmond Wentworth Cotter, M.A., M.B., B.C., Camb. M.R.C.S., L.R.C.P., Lond., son of the late Duncan Donald Darroch Cotter, Co. Cork, Ireland, to Muriel Isabel, youngest daughter of Samuel James Musson, of Norwood.

Deaths.

TOMLIN.—On April 13th, at Wood Green, Robert Francis Tomlin, M.R.C.S., L.S.A., aged 52.

VOL. CXXXII.

WEDNESDAY, APRIL 25, 1906.

No. 17.

NOTES AND COMMENTS.

Religion and Vivisection.

CAN a man of deep religious conviction be a vivisector? The overwhelming majority of medical men would answer in the affirmative. There are many worthy folk, however, who think otherwise. To them the practice of vivisection is a thing accursed, and they refuse to regard its practice as consistent with the higher moral attributes. In an obituary notice of the late Sir John Burdon Sanderson, we said of that distinguished man of science: "In private life he was imbued with deep religious convictions, and was a member of the Presbyterian Church. In spite of his gentleness and humanity, he has been fiercely assailed by the anti-vivisectionists." That notice brought us a letter from one of that band of restless critics, who regretfully asked how anyone could possibly possess deep religious convictions and humanity and be at the same time a vivisector. The writer might just as well ask, Can anyone be possessed of deep religious convictions and shoot a partridge, or hook a trout, or cut the throat of a calf or a bullock? All those things are done continuously to supply sustenance—and haply "sport"—to mankind; yet, viewed in cold blood, they are acts of revolting cruelty or of despicably mean cunning.

The Evil Spirit called Satan.

DOES our critic—we wonder—eat of the partridge or of the trout, or of the beef brought to his table as the result of abominable cruelty and treachery to lower animals? If so, he does it to preserve his own life and well-being; and yet, from the tone of his letter, he evidently assumes that he, at any rate, is better than men like Sir Burdon Sanderson, who assume the right of experimentation upon the lower animals in order to lessen the sum-total of human suffering. "Can it be thought," pursues our critic, "that it pleases the Deity for men to seize the dumb creatures he has made and torture them in the hope of improving the health of the human species? If it does, where is the difference between the Deity and the evil spirit we call Satan." Well, it seems to us that if man is entitled to seize dumb creatures and "torture" them with an eye to sport, food, personal ornament, bodily service, and so on, that he is equally justified in subordinating their welfare to his own by way of experimentation. If a man, to be religious and humane, must keep his hands off "defenceless creatures" in the laboratory, he must do so equally in field and forest, in pigeon-shooting enclosures, in streams, rivers, and lochs, in the slaughterhouse—in fact, everywhere. If there must be a law for this branch of morality, let it be applied all round, dear Anti-Vivisector.

The decision of the War Office in the notorious "ragging" case and Army Reform. The decision of the War Office in the notorious "ragging" case and Army Reform. Its outcome will be regarded by the majority of law-abiding citizens with approval. It relieves the Commanding Officer and the Adjutant of their appointments, and deprives the four lieutenants concerned of a year's seniority. Any less rigorous treatment of the scandal would have rendered the situation intolerable to the average man in the street. As it is, this speedy and decisive handling of a thorny incident right in the heart of military privilege makes us hope that the era of reform has at last really begun to illumine the gloomy recesses of the Horse Guards. Army abuses and scandals have often been brought to light, but inquiry has been either scotched or punishment evaded. In this case investigation has been prompt and public, and the subsequent sentence fair and fearless. The decision promises well for the future of Army administration.

What about Army Medical Reform?

So encouraging is the prospect that it infuses fresh hopefulness into the desire for Army Medical reform. The inherent rottenness of the present system was shown by that vast exposure of Army shams—the Boer war. Something has been done since then to mend matters—but not a tithe of that which is urgently needed. Were a great war to come upon us to-morrow the Army Medical Department would be hardly a whit better prepared than it was in South Africa. The British mortality from enteric fever, to take one point only, was enormous. The Japanese have recently gone through an infinitely greater campaign with a nominal loss from that malady. In other words the Japanese Army Medical Department was perfectly organised from the standpoints both of science and of administration. The British Army Medical department, on the other hand, presented a complex muddle of rival interests, compounded of official jealousy, incompetence and *laissez faire*, the outcome mainly of the starvation and stern suppression of the medical department by the military authorities.

Mr. Haldane the War Minister.

Clearly, a strong man is now at the head of the military arm. The strength of a Hercules, for that matter, is required to clear the Augean stable. It is to Mr. Haldane, the War Minister, that we must in future look for reform in Army Medical Administration. As a minor but not unimportant matter it would be well for him to inquire into the system that permits civilians to be appointed to surgeoncies

in the Household Troops. Then there is the important question of professional secrecy to which we alluded last week. We expressed our opinion that Surgeon-Major Whiston, in reporting to the Colonel that a person under his command in his opinion suffered from scabies, was thereby committing a serious breach of professional confidence. It may be that the Army authorities think they have a right to such knowledge, but we can conceive no responsible code of medical ethics that would permit of the divulging of such purely professional information. It would be well for Mr. Haldane to point out to the military authorities that they have no right to ask for such information except with the consent of the soldier involved. Besides, the individual surgeon may be wrong. Surgeon Major Whiston's view was contrary to that of several other military surgeons.

LEADING ARTICLE.

PUBLIC NEWSPAPERS AND CERTAIN ADVERTISEMENTS

IN our crusade against the advertisement of remedies of questionable character in the lay newspapers, we pointed out various advertisements of the kind in our contemporary *Truth*. The good work performed by that journal in exposing quackery has always been freely and gratefully acknowledged by us, but we considered it none the less our duty to draw attention to what appeared to be inconsistencies between the editorial creed and the editorial performance. The tone of the answer vouchsafed to us by the Editor is simply amazing. Instead of one of the calm, judicial and closely reasoned articles in which our contemporary is wont to express his views, he has favoured us with four columns of explosive rhodomontade under the elegant title of "Keeping Your Hair On." Even with pen in hand the writer is constrained to utter a half apology for his vulgarity, in advising the Editor of the MEDICAL PRESS AND CIRCULAR to "keep his hair on." However, disputes are not settled by the elegancies of Billingsgate, so we pass on to notice the gist of his defence. Our first criticism was directed against proprietary applications sold under the title of "hair food." We had assumed that all educated persons would be aware of the fact that hair could not be nourished by external applications. Hairdressers, of course, assert the opposite, partly through sheer ignorance, and partly, no doubt, because that teaching favours the sale of their nostrums. The Editor of *Truth*, apparently, has adopted the views of his barber, and possibly also those of John Strange Winter who advertises with him to the same effect. He says that the information as to the inherent worthlessness of any application as a hair food is news to him, and he has no doubt it will be to 999 people out of every thousand. So great was our respect for his journalistic and worldly acumen, that we should have imagined him to represent the odd man in this connection. Instead of that, however, he comments on the impertinence of an unknown journalist to pronounce *ex cathedra*

what tens of thousands of persons believe, on the strength of their own experience, to be a physiological fact. We may remind *Truth* that the efficacy of Count Mattei's remedies in cancer and other serious maladies were vouched for by a host of persons whose *bona fides* was above suspicion, yet analysis showed those remedies to consist of nothing but water. But in framing his tirade the Editor of *Truth* has wandered from the hair food, which is arrant nonsense, and has got on the firmer ground of a hair stimulant, assuming, that is to say, that an old-established medical journal may speak confidently about such simple matters. Years ago we believe the Editor of *Truth* challenged another editor who had assaulted him to fight a duel. He has not on this occasion faced us with so fierce an issue, but nevertheless threatens us with a proxy in the shape of Mr. George R. Sims, whom he advises us quite gratuitously not to fall foul of. The eminent journalist in question, as everyone knows, is interested in a hair lotion, but we are not aware that he has ever advertised it as a hair food, so that the introduction of his client's name hardly strengthens the case for *Truth*. At the same time we may remark incidentally that writers whose names are household words are not likely to add to their ultimate reputation by embarking in trade ventures connected with the sale of nostrums. So much for hair food; now for the "Ganesh" remedies, about which the Editor of *Truth* has little to say. So reticent does he become that he makes no specific allusion whatever either to Mrs. Adair or to the Ganesh remedies—and their prices. In making a quotation from our original article he actually replaces Mrs. Adair's name with a dash. Now, supposing the Editor of *Truth* to be excusable for not knowing the impossibility of feeding hair as one would feed rabbits or white mice, is he to be excused for not recognising the hollowness of the claim to cure wrinkles by wearing a "Ganesh" strap stuffed "with fragrant herbs," and sold at £1 5s. 6d.? His answer to that is simply to drop Ganesh and drift away into vague generalities. We presume he is more or less in honour bound to stick by his advertisers. It is not usual, however, for *Truth* to be reticent about names in leading articles. As a rule names are dragged into the light of day with relentless hand, and the arguments connected with them developed with the closeness and care of a mathematical demonstration. Here a show of refuting us is made by a quotation from a popular writer, Dr. Andrew Wilson. That gentleman, however, cannot for a moment be accepted as a scientific medical authority. Above all, the quotation given (source not stated) simply asserts that the growth of hair may be promoted by suitable lotions. What bearing has that upon hair food as apart from hair stimulation, substituted for fairly obvious reasons by the Editor of *Truth*? In conclusion we can only say that *Truth* has now received due warning as to the medical view of such things as "Ganesh" muscle oil, and wrinkle straps, and other Ganesh remedies, sold at prices varying from 3s. 6d. to £1 1s. and £1 10s. 6d. each (the fragrant strap costs a guinea and £1 5s. 6d. each.) and advertised at rates known only to publishers and their clients

NOTES ON CURRENT TOPICS.

Danger Signal for the Deaf.

In these days of motor-cars and motor bicycles some outward and visible indication of hardness of hearing has become well-nigh indispensable if the victims of that infirmity are not to be slowly but surely exterminated by unwary *chauffeurs*. In steering these too progressive vehicles the driver naturally acts on the assumption that his noisy advent will elicit certain reflexes on the part of pedestrians and drivers of horse-drawn conveyances, and he naturally expects his trumpet warnings to receive some formal recognition by a change of location or direction. An unexpected failure to respond thereto by the prospective victim is extremely likely to lead to his conversion into what the American poet has likened as "trod-upon raspberry tart," and under such circumstances it would be hardly just to saddle the horrified chauffeur with the whole of the blame. There was nothing to indicate to him that his sonorous appeal for space had fallen upon unreciprocative ear-drums, and before that fact had dawned upon him the accident would have happened, and there is one deaf person the less in the world. This special added liability of the deaf to the risks of the road, a liability which will become greater as years roll by, suggests the propriety of the hard of hearing—for it is not only the stone-deaf that we have in view—adopting some distinctive mark of their infirmity. There is nothing dishonourable in being hard of hearing, and even in ordinary social intercourse it would often be a boon to be made aware of the defective auditory condition of one's interlocutor. We must leave it to the afflicted to select the differential mark. a coloured hatband, a red umbrella, or what not, Only it were well done if it were done quickly.

The Tragic Fate of M. Curie.

In these modern days a great scientist occupies a place among the heroes of mankind. The discoverer of Radium, for instance, ranks in the minds of the present generation in much the same way as Christopher Columbus, or Alexander the Great, or Mark Antony did in those of bygone ages. It is indeed an irony of fate that one of the world's greatest scientific discoverers should be cut off in his prime by a street accident. While walking in the streets of Paris on the 19th instant he was unfortunately knocked down by a cab. At the same instant a heavy van coming from the opposite direction ran over his prostrate body and crushed him to death upon the spot. It is characteristic of the simplicity of a great mind that M. Curie refused the Cross of the Legion of Honour offered him by the French Government upon the announcement of his famous discovery. It is no less characteristic of the nobility of true science that he published his discovery freely to all mankind. The sympathies not only of France, which has prematurely lost one of her most distinguished men of science, but also of the whole

world, which shares in that calamity, will be accorded to Madame Curie, who divides with her late husband the glory of the discovery of radium. It is to be hoped that the world generally will be afforded an opportunity of contributing to the erection of an international monument in the shape of a Research University.

Dusty Throats.

THE recent spell of dry weather and the multiplication of motor vehicles raises the question as to the best means of laying the resulting dust. Those who career blissfully and rapidly throughout the country do not see one tenth of the trouble they are creating in their wake, for it is not exaggerating in the least to say that there are certain localities, right in the midst of pure country air, where the dust never settles until long after nightfall. Irritating the eyes of pedestrians and cyclists, hiding the green of the hedgerows beneath a greyish-white film, penetrating houses, ruining furniture and books, contaminating food, and depreciating house property, the dust-fiend wields his unholy sway unlet and unhindered. From the medical aspect, we hear of epidemics of a peculiar variety of sore-throat, due partly to actual mechanical irritation by dust particles and partly to germs. It is true that the nose acts as a natural filter, but it cannot be expected to keep back every dust-particle, not to mention micro-organisms. The remedy is hard to find and doubtless many experiments will have to be undertaken before any practical solution of the dust problem is forthcoming. Some form of tar treatment of main roads appears to have been fairly successful in those places where it has been adopted. The evils of dust are too well-known for any pains to be spared in combating this new danger of modern life.

Success in Failure.

It is not possible accurately to compare Medicine as a career with that of the Bar for there are obvious differences between the two callings; but if taken in their higher branches it may truthfully be said that they share in common the advantages and disadvantages presented by the influence, wealth, and social connection of their adherents. We lately drew attention to the surprising statement in Sir Frederick Treves' vigorous rectorial address at Aberdeen to the effect that success in medicine depended on merit and merit alone, the possession of money and influence operating rather to the disadvantage of the possessor. Our readers may be interested to compare this utterance of perhaps the most successful surgeon of modern times with one made by probably the most distinguished lawyer of to-day. The Lord Chancellor presiding at the annual meeting of the Barristers' Benevolent Association appealed for subscriptions from the more fortunate members of the Bar in favour of the less fortunate. "For," said he, "I am not one of those who think that success at the Bar is even approximately proportioned to merit." This may have sounded a hard saying to an audience of legal peers, high-court judges,

and distinguished K.C.'s, but who will deny that it is far nearer the truth than would have been a jaunty reference to the principles of self-denial and hard-work as the sole factors in success? In Medicine, as at the Bar, worth and ability have their chance, but the handicap is great. Perhaps some day a Cabinet of Labour Legislators will change all this.

Typhoid at Fulbourn Asylum.

A SIGNIFICANT report by Dr. Monckton Cope-man on the late outbreak of typhoid at Fulbourn Asylum, near Cambridge, has been issued by the Local Government Board, and it brings to light a state of affairs which reflects little credit on the sanitary organisation of this country. In 1902 the Local Government Board while sanctioning some loans for the extension of the asylum wrote to the Town Council of Cambridge, pointing out the danger caused to their water-supply through the proximity of the asylum sewage farm. After considerable delay the town council reported the matter to the waterworks company, and the latter wrote to the Board asking for their advice. The Board replied that they were not responsible for advice, but sent copies of the correspondence to the Asylum Committee, to the Town Council of Cambridge, and the Lunacy Commissioners. The Lunacy Commissioners wrote a strong, courteously-worded letter to the Asylum Committee pointing out that the danger was a real one, and urging that the advice of a sanitary expert should be taken and a consultation with the directors of the waterworks arranged. Three weeks later the clerk to the Asylum Committee replied that they did not admit the danger, but if the directors liked to propose a consultation they were prepared to meet them. After this, nothing was done till the inevitable outbreak of typhoid occurred, the irony of fate being exhibited in the fact that it was the asylum itself that suffered from the contamination of their own water. The whole story reflects about as little credit as could be on everyone concerned.

A Successful Action.

It is always pleasant to be able to record the success of medical men in vindicating their character and competency, and we are again able to do so in a recent case at Wolverhampton. The plaintiff had attended the daughter of the defendant for scarlet fever in October, and being convalescent in November the child was allowed to get up and go into a tower adjoining her bedroom. Some days later she developed rheumatism with cardiac complications, and of these she died two months later. No allegations of negligence or want of skill were made till the doctor sent in his account four months later, when the defendant suggested that it was the doctor's fault that the child had contracted rheumatism, and he refused payment. After medical evidence had been called to show that rheumatism was a well-recognised complication of scarlet fever and that there was no negligence in the doctor's action, the jury found

for the plaintiff, and judgment was given in his favour for the full amount. It is significant of the attitude of people of the type of the defendant that the doctor was allowed to continue attendance throughout the illness, and that the trouble only arose when the bill was sent in.

Bald Novelists.

IT is a general cry of a certain section of the literary world that novel-writing does not pay, and one can only be thankful that the public taste is even as good as it is if the bulk of trashy stories that are put on the market fail to attract many readers. One thing, however, that does seem to pay is for a novelist to be bald, but the right way to make money out of this affliction is first of all to deplore the fact in public and secondly to induce people to buy the stuff that cured the defect. Mr. George R. Sims boldly led the fashion among bald novelists, and stimulated by his success the lady who writes under the name of "John Strange Winter" has followed suit. A brochure, entitled "Comely Woman," is now being sent out broadcast to tell how the writer suffered from all sorts of hair ailments and how she found salvation in a preparation of her own elucidation! With a generous desire not to keep a good thing to herself, Mrs. Stannard now offers this stuff to the world at half-a-crown a bottle. Moreover, if it should miss fire she has other shots in her locker, and a whole whirligig of hair foods, creams, and washes may be run through before the sufferer either finds herself supplied with a headful of bushy hair or exhausted in patience and pocket. The only thing necessary to success in the hair-producing and baldness-curing business seems to be ignorance of pathology and ability to advertise, and now that the bald novelists have realised these facts we may expect them to abstract large sums from the credulous.

A Hospital Dodge.

THE difficulties which hospitals in certain cases experience when they wish to inspire confidence in the public mind sometimes lead them into devious paths, but we imagine that nothing done in this country ever equalled in impudence a dodge that was recently perpetrated in America. A certain institution calling itself the "Christian Hospital"—whether for the practice of scientific or unscientific Christianity does not appear—wishing to gain prestige elected *in absentia* the well-known Chicago surgeon, Dr. John B. Murphy, as President of the Medical and Surgical Staff. The honour was one undreamed of by Dr. Murphy and one which he promptly disowned, but the Christian Hospital, imbued with the spirit of their religion, continued to give honour where honour was due, without regard to the feelings of the recipient. Dr. Murphy, therefore, took the prosaic course of going to law, and we are glad to learn that he obtained an injunction restraining the hospital from using his name, together with £50 damages for their having done so in the past. Dr. Murphy is sincerely to be congratulated not

only in having effectively exposed the trick that was played him, but also on having demonstrated that the law in America gives a medical man some guarantee against the improper use of his name. The way that some well-known names in this country are exploited by unscrupulous people for commercial purposes is a scandal.

Phrenology.

AMONG the curious survivals of the unfit is the continued existence of the "science" of phrenology, which still possesses a society, and, presumably, members to subscribe to its funds. Mr. James Webb, the President of the Society, gave an address last week on "Bumps and their Meaning," in which he maintained that the salvation of our national mentality lies in the study of phrenology. If this be the only hope, we fear there is little prospect of the national sanity of the future. It is not a little curious that with the development of neurology and the elucidation of the functions of the different cerebral areas that the stupid empirical myths about bumps and their mental significance should not have perished, as belief in witchcraft and the evil eye have, in the light of fuller culture. The anthropometrical conclusions of the phrenologists have been shown over and over again to have no basis in fact, and to be unworthy of credence by serious people, but as a monument to human gullibility the Phrenological Society survives. Mr. Webb would like to see the study taken up in earnest by medical men, especially those engaged in asylum work; our lunacy records, says he, are seriously increasing and there is no proportionate increase in cures. Granted that doctors in asylums should have plenty of material on which to study clinical phrenology, we fail to see how their work in this direction would influence the number of cures. If they could begin by the abolition of the Phrenological Society, one cause at least of mental instability would be removed from our midst.

The Historical Medical Exhibition, London.

It is now some time since the scheme for a comprehensive historical medical exhibition was announced. It is gratifying to learn that the proposal, so far from being abandoned, has been in the meantime gathering strength and completeness. The scope of such an undertaking is simply enormous, covering as it does the whole history of medicine from prehistoric days up to the present period. Its organiser, Mr. Henry S. Wellcome, may be congratulated upon the inception and the carrying out of so gargantuan a project. In a circular addressed to the medical profession he asks for the loan of articles of interest of any age and any clime. It is to be hoped that medical men who have in their possession anything of the kind will at once place it at the disposal of Mr. Wellcome. The result of this collection should be to reduce, as it were, in panoramic form the evolution of the great science and art of healing. The precise date of the forthcoming exhibition is

not yet definitely announced, but that omission can hardly be wondered at in view of the vastness of the undertaking. It is to be hoped that the main features of the whole thing will be embalmed in some enduring form for the pleasure and instruction of future generations. With the completion of this project Mr. Wellcome will have done much to render his name remarkable in the annals of medical history.

PERSONAL.

"AN expression of the displeasure" of the Army Council is to be conveyed to Surgeon-Major P. H. Whiston in disapproval of his action in the recent case of "ragging" in the 1st Battalion Scots Guards.

PRINCESS CHRISTIAN will open a bazaar at Doncaster to-morrow, Thursday, in aid of the Doncaster Infirmary. The Corporation will present an address of welcome to the Princess.

DR. JOHN CAMPBELL, of Belfast, has been elected a Representative of Convocation on the Senate of the Royal University of Ireland.

LAST week Mr. C. G. Wheelhouse, J.P., received a handsome presentation on the occasion of his retiring from the Presidency of the Filey Club, which he had held for thirteen years. The inscription on the salver was as follows:—Presented to Claudius Galen Wheelhouse, LL.D., J.P., for 13 years President of the Filey Constitutional Club, by the members and their friends, as a token of their respect and esteem.—April 16th, 1906."

THE late Mrs. Mary Day, of Lulsley, Worcestershire, bequeathed £2,000 to the Worcester Infirmary, £1,000 to the Brompton Hospital for Consumption, and £500 each to the Worcester Dispensary and the Birmingham Blind Asylum.

THE annual meeting of the British Association for the Advancement of Science, which is to take place this year in York, will begin on August 1st with an address by the President-elect, Professor Ray Lankester, F.R.S.

A COMPLIMENTARY dinner to Dr. T. F. Dewar, Arbroath, who is leaving the town to take up the duties of medical officer of health for the county, is to be held on the 26th of this month.

MR. BRYDEN GLENDINNING, M.B., has been appointed physician to H.R.H. Princess Ena of Battenberg, the bride elect of the King of Spain. He was formerly house physician at the British Hospital in Paris.

DR. ARCHIBALD R. DOUGLAS, resident medical officer at the Royal Albert Asylum, Lancaster, has been appointed Medical Superintendent.

At the recent graduation ceremonial at the University of Edinburgh, on April 12th, the following distinguished persons, amongst others, received the degree of Doctor of Laws (LL.D.):—His Grace the Duke of Bedford; Dr. Alexander Graham Bell, the inventor of the telephone and a native of Edinburgh; His Excellency Wirklicher Geheimrat, Dr. Ernst von Bergmann, professor of surgery and director of the Royal Surgical Clinique in the University of Berlin; Dr. David Christison, son of Sir Robert Christison, and known for his archaeological attainments; Professor George Dancer Thane, of University College, London; Mr. A. Taylor Innes, Mr. William Crawthorne Unwin, F.R.S., and Miss Louisa Stevenson.

A CLINICAL LECTURE ON THE TREATMENT OF HÆMATURIA OF RENAL ORIGIN.

By T. GELSTON ATKINS, B.A., M.D., M.Ch.,
Surgeon to the Cork South Infirmary and County Hospital.

A Summary of Cliniques delivered in the South Infirmary during the Session 1905-1906.

In applying ourselves to the treatment of hæmaturia of renal origin we must in the first place inquire as to the various pathological causes which produce bleeding from the kidney, for no sound and rational line of treatment can be adopted with any degree of success that has not for its basis the exact pathological causative condition of the hæmaturia.

The various pathological causative conditions of renal hæmorrhage may be divided into (a) traumatic, (b) toxic (drug) and dietetic, and (c) disease. We will, therefore, discuss the treatment of each of these conditions, pre-supposing that only a few remarks on the diagnosis of each condition is sufficient, as, otherwise, it would lengthen this paper to an unjustifiable degree. And, first, with regard to traumatic causes, they are usually due to severe crushings, falls that produce more or less laceration of the renal substance, partial or complete, and manifest this to us by a profuse bright red hæmaturia, which is usually recognised by the local evidence of pain or some external visible local injury. If the convex border of the kidney is lacerated there is a perirenal hæmorrhage, which manifests itself by a sudden swelling in the loin, which, from its sudden onset, must be a hæmatoma. The quantity of blood lost usually varies from slight bleeding to a most profuse hæmorrhage, which may so blanch the patient and produce such collapse that death from this hæmorrhage may ensue. When called to a case of moderate severity, the following treatment I have found very successful. Perfect rest, and continuous cold, in the shape of Leiter's coil, to the loin, with internal styptics. I have seen good follow the use of ergot, given as ergotin g. 1-50 every two, three, or four hours, or oftener. I have also seen good from ergot combined with gallic acid, but I think I have seen more good from twenty-drop doses of adrenalin chlor. (1 in 1,000) every hour than from any other internal remedy. I have also seen benefit from opium. If the bleeding is so profuse as to fill the bladder quickly with blood, it coagulates, and when coagula and urine become mixed, there is great pain set up, which is aggravated by any attempt at the act of micturition, until finally a clot gets impacted in the urethra, which completely prevents any urine being voided. Under these conditions I have found that aspiration of the bladder with the largest possible litholapaxy cannula that will pass breaks up the clot, and so enables, after a time, the bladder to expel its own contents. During this period I usually suggest the exhibition of some urinary antiseptic, as uriform, urotropine, helmisthol, as it is most important to prevent sepsis in the urinary tract. In the meantime the patient sucks ice freely, or takes iced milk, or iced milk and salutaris, or other simple plain non-irritant mineral water, no solids being allowed until the hæmorrhage is controlled.

Should the hæmorrhage be not arrested by these means, or should the patient's condition from the first show that some large vessel must be bleeding, as evidenced by the rapid formation of hæmatomas, in the loin, in the bladder, &c., I would strongly urge that the kidney should at once be explored, through the usual loin incision, and then dealt with according to the conditions found, by a thorough cleansing of the laceration and possibly suture of the renal substances by deep catgut sutures, passed with blunt round (no cutting edge) needles. In addition to this, you could then pack in sterilised gauze, plain, or saturated with sterilised adrenal chlor. solution, which would act

as a drain as well. Should, however, the kidney be so severely lacerated as to be incapable of suturing it with the certainty of arresting hæmorrhage, or should a large branch of the renal artery be lacerated (that branch may possibly be ligatured), then you must have recourse to nephrectomy, and, in severe cases, when the patient seems rapidly losing ground, where the pulse is getting faster and weaker, I would not delay. I should, however, considering the necessary shock of the operation, give an intra-cellular or intravenous injection of normal saline, either before the operation or during its performance, and, generally speaking, treat any complication that might arise by the means that seemed best suited for that particular complication in the individual cases now being dealt with.

(b) CASES OF TOXIC, OR DRUG, OR DIETETIC HÆMATURIA.

It is well known that certain drugs, as turpentine and cantharides, irritate the kidney and produce hæmorrhage. The withdrawing of these drugs is usually sufficient to arrest the bleeding set up by them, and simple rest and a fluid diet completes the cure. So, also, with the hæmaturia of diet. There are certain articles of diet, such as rhubarb and asparagus, or vegetables generally speaking that contain large quantities of oxalates that produce renal hæmaturia. I have at present under my care a gentleman, now æt. about 75, who for as long as I have known him—fifteen years or more—bleeds from his left kidney whenever he eats even one blade of asparagus. The cessation of the asparagus always cures the symptom.

It is more than doubtful that kidneys so easily affected are themselves the subject of some chronic affection; for, in the instance noted above, this gentleman in the last few years has developed a gouty kidney, so that in the pre-stages of this disease, his renal vessels (capillaries) were evidently easily ruptured by the irritant action of the oxalates contained in the asparagus.

We now have to discuss the treatment of the third group.

(c) THE HÆMATURIAS OF DISEASE (RENAL).

The appearance of blood in the course of such general diseases as typhus fever, measles, small-pox, rheumatic fever, or the hæmaturia after cholera, do not seem to call for any special treatment, unless they become excessive, when probably only cupping over the kidneys and a gallic acid mixture or adrenal chlor., will suffice to moderate or check the hæmorrhage, which is due to a toxic congestion of the kidney.

We must now come to that large and important group of hæmaturias which are due to diseased or disorganised states of the kidney itself.

The hæmaturias which accompany kidney disease may be *symptomless*, or they may be accompanied by a series of symptoms, as pain, pyuria, abnormal urination, &c. This serves as a basis of classification of the renal group (A). Symptomless and painless hæmaturia: We find the onset may be sudden, and may be repeated at frequent or infrequent intervals, and the quantity of blood lost may vary from a mere trace to a very profuse and persisting hæmorrhage. This may be the local expression in the kidney of such general systemic diseases as (1) granular kidney, (2) renal syphiloma, (3) cardiac disease; or, it may occur in purely renal conditions as (4) cirrhotic kidney, or (5) angioma or capillary nævus of a renal papilla, or in (6) benign or malignant disease of the kidney, or in (7) rare cases of embedded aseptic renal calculus, or in (8) submucous deposits of crude tubercle (Fenwick).

Of the renal group (B): We find the hæmaturia pronounced and combined with other symptoms, as pain, local or referred, pyuria, abnormal urination, and altered chemical states of the urine. These conditions, more or less, we find in the following states: (1) Chronic granular nephritis (infected); (2) local interstitial nephritis (3) movable kidney (ureter), to twist or narrowing of, or obstruction of, the ureter. (These are all conditions I have frequently seen). (4) Benign or malignant growth of the kidney; (5) renal calculus; (6) renal tubercle; (both common). (N.B.—Renal tubercle I believe to be far more common than was formerly supposed.)

In dealing with the treatment of the hæmaturias of the above conditions, it would be a serious omission to omit any mention of the cystoscope—that marvellous instrument which has practically revolutionised diagnosis, and hence has given precision to methods of treatment of all the diseases of the urinary organs. By its use the blood can be seen flowing from the ureter, the various conditions of the ureteric orifices can be ascertained, and very often from these conditions the affected kidney can be localised, the ureters can be catheterised, and the urine from each kidney obtained separately, which can then be submitted to careful chemical, microscopic, and bacteriological examination; the pelvis of the kidneys can be washed out, and, if necessary, topical remedies can be applied to the pelvis of the kidneys. In this way sterile hæmodynamic agents can be brought into direct contact with the interior of the kidney with good hope of arresting hæmorrhage from the pelvis and calyces.

The hæmaturia of chronic granular kidney, if not excessive, will usually arrest itself without any very special treatment, as it is usually due to increased arterial tension; the loss of blood lowers this and hence is a "curative hæmaturia." If, however, it should become excessive or persistent, as it sometimes does when an acute nephritis is superadded to the chronic disease, then dry-cupping to the loins and hot packs will be of benefit. I have seen iron-alum in 5 grain doses do good; I have also seen ergot and gallic acid apparently arrest the bleeding. Opium is a drug which may no doubt at times arrest the bleeding but it also arrests the action of the kidney, and so may be in this respect injurious.

So also is it with the hæmaturia of cardiac disease. It may be a conservative action, and is not to be unnecessarily interfered with. Should it become excessive the treatment of the cardiac condition will usually suffice to arrest it, and, if not, any of the usual medicinal methods may be tried.

In the treatment of hæmaturias depending on renal syphilomas, the exhibition of rapidly increasing doses of iodides, with or without the addition of adrenal chloride, will rapidly cause a diminution of the bleeding and finally its arrest.

Referring again to the treatment of the hæmaturia of chronic granular nephritis, we may now and then, when ordinary treatment fails, and when it is apparent from the advancing anæmia that unless some means be adopted to bring the bleeding to an end the patient will die, be called upon to ask ourselves whether operative treatment should be adopted. It is a well-known fact that, since the routine use of the cystoscope in those cases, the bleeding has been seen to proceed usually from only *one* kidney, and that cutting into the cortex of this kidney has caused the bleeding to cease. Since Edeboh has introduced the method of renal decapsulation, for the cure of chronic nephritis, hæmaturias have been controlled, and hence we may say that in obstinate cases of renal hæmaturia due to chronic nephritis surgical intervention should be adopted at a much earlier stage of the disease than was formerly the case. Time alone will tell, when large numbers of such cases have been operated upon, of the exact value of this method of treatment.

We now have to discuss the treatment of that rare and obscure form of hæmaturia depending on angioma or capillary nævus of a renal papillæ (Fen-

wick). Some three or four years ago I was consulted with reference to a severe but intermittent bright-red hæmaturia occurring in the person of a girl, æt. 19, and which usually commenced without any apparent cause, about a week after the cessation of the menstrual period. The hæmaturia was symptomless, and the urine did not contain pus. Tubercle bacilli were not then examined for with the certainty in which they can now be detected. With the cystoscope the blood was seen pouring out of the right ureter. The right kidney was explored and its interior freely examined for ureteral stone, with the finger, with a negative result; but in twenty-four hours after the hæmorrhage ceased, and had not recurred when the patient was last heard of about eighteen months ago. The exact pathology of this case was not discovered at the operation, but in all probability it was a case of capillary nævus or a renal papillæ or angioma, as described by Mr. Fenwick.

In such a case as this, where a microscopic examination of the blood shows that it is leaking from the mucous surfaces of the pelvis or calyces, I would be strongly inclined to wash out the pelvis of the kidney, by means of the ureter catheter cystoscope, with sterile salt solution containing either adrenal chlor. or hazeline, and I should any way expect some temporary cessation of the hæmorrhage, which would at times be most important, pending the arrangements, &c., for an operation. These cases are some of the most obscure, in the whole range of kidney disease, both from a diagnostic and prognostic point of view, as well as from the point of view of treatment.

Fenwick has been able in several cases to cut into the kidney and excise, by sharp spoon, the angiomatous papillæ, and he states that in his experience these are usually found in the inferior pole of the kidney, but that they may be tucked very high up in a calyx, and so may be missed by the incision; so he suggests that the exploration should be done somewhat roughly. This seems to be what I unconsciously did in the case already cited, when after the exploration the bleeding ceased.

The exact pathology of such cases is extremely interesting, but is not a subject for the present remarks except in so far as it suggests the above methods of treatment.

In the treatment of hæmaturias of benign and malignant growths, we are able to locate by means of the cystoscope the side from which the hæmorrhage proceeds. In the early stages of these cases there is usually not any renal tumour or renal pain, which would enable the kidney from which the hæmorrhage proceeded to be localised. By examining *during* an hæmaturial period, we can note which ureteric orifice the bleeding proceeds from, or, if the hæmorrhage has ceased, we can notice the condition of the ureteric orifice, which is usually elongated, with its lips swollen, not unlike the orifice of a swollen male urethra, stained a reddish yellow colour, or, in the absence of this, we sometimes find that well-marked small vessel twigs proceed up to the orifice of the ureter, and this enables us to say that the corresponding kidney has been the seat of the hæmorrhage; but we must also remember that in these cases the bleeding may proceed *through* a perfectly normal ureteric orifice. I have now been watching a case of severe intermittent renal hæmorrhage, due to renal carcinoma for several years, and the ureteric orifice is still perfectly healthy on cystoscopic examination in the intervals between the attacks of hæmorrhage.

I would here strongly protest against any operative interference being undertaken, until the kidney from which the hæmorrhage proceeds is located. If on cystoscopic examination there is no blood seen issuing from the ureter, and the condition of the ureteric orifices do not give *exact* information as to which is the diseased kidney, then *no* operative treatment should be undertaken until another examination is made *during the next attack of hæmaturia*, when the blood can be detected issuing from the ureteric orifice corresponding to the diseased kidney. Nephrectomy is

the operation in malignant disease, when that can be done with a due hope of being successful, *i.e.*, before there is any evidence of general systemic infection.

In the hæmaturias of advanced malignant disease, where there is a renal tumour and systemic infection, operation may have to be undertaken with a view to simply arrest the hæmorrhage; and so for the time being prolong the patient's life. If operation is either declined or if other conditions seem to contra-indicate it, I have seen the hæmorrhage arrested by ergole in combination with large doses of calcium chlor. In the case cited, adrenaline, even in large repeated doses failed to even moderate the hæmorrhage; nevertheless, it is one of the drugs that should be fully and freely exhibited in such cases. Hypodermics of ergot in one of its many preparations should receive a trial, and so should turpentine. This is also a class of case where I think direct astringents might be tried by means of the ureter catheter. These solutions should be sterile and should be slowly syphoned in, in such quantities as not to produce severe renal pain.

In benign growths the kidney must be explored, and if it is considered possible to excise the growth this can be done, or a free incision into the renal pelvis, breaking up the capillaries freely, may suffice to arrest the bleeding, and if this fails then recourse must be had to extirpation, partial or complete, of the kidney.

Passing now to the treatment of hæmaturia of embedded aseptic stone, I may remark that, according to Fenwick, this class of symptomless hæmaturia occurs in only 2 or 3 per cent. of all such cases in adults, though it is much more frequent in children. The treatment consists in exploring the kidney and removing the stone, when, as a rule, the hæmorrhage ceases.

In the bleeding of deposits of crude tubercle under the mucous membrane of the pelvis, immediate removal of the kidney—to remove the tuberculous foci as quickly as possible—is the line of treatment to be adopted. It may be possible, with increased knowledge as to the limitations of the tuberculous foci, to excise them, and leave the remaining healthy portions of kidney substance. This, of course, implies that the disease is not extensive, and that it is more or less localised.

We must now turn to the treatment of hæmaturia in group (B), that is, in hæmaturia accompanied by symptoms of pain, pyuria, &c. It is absolutely necessary that we should accurately localise the source of the bleeding, for it often happens that one sees cases of hæmaturia accompanied by renal pain, referred to one or other kidney, but that when such a case is examined by the cystoscope during a hæmaturial attack the bleeding is seen to come from the ureter on the side opposite to that of the painful or aching kidney. I have seen many cases of slight hæmaturia occurring in right movable kidneys, when the pain was complained of altogether in the left side, which hæmaturia and pain were completely cured by fixation of the right kidney. Doubtless this pain is produced by some back pressure through the left ureter, causing slight distension of the pelvis of the kidney.

In this group (B) we find cases of chronic granular nephritis of the infected type. The treatment of the hæmaturia would be the same as that of a similar condition, grouped under the symptomless hæmaturias. There is, however, considerable difficulty in diagnosing whether the hæmorrhage is due to an infected granular kidney or to an aseptic stone.

I have at present under my care a man, æt. about 60, who for several years has complained of left loin pain (renal), with intermittent attacks of severe hæmaturia. The microscopy of the urine, which is acid, and of sp. gr. 1018, usually gives a few hyaline casts, a few oxalates of lime crystals, some cells, apparently from the renal pelvis. Skiagraphy gives a negative result, and cystoscopy only shows a somewhat enlarged middle lobe of his prostate, no change in the ureteric orifices, and the efflux seems normal. He has no cardio-vascular changes. Some months ago, he states that during an attack of hæmaturia he passed some calculous material,

Here is a case, then, that it is almost impossible to say whether the hæmaturial attacks are due to infected nephritis or to embedded aseptic stone. Clearly it is a case for exploration of the kidney, which I hope shortly to do.* The hæmorrhage and superadded pain may be due to irritation of the oxalate crystals, or to some shifting of the kidney, or to infection from the bladder. In either of these cases exploration, followed by free separation of all adhesions and incision of cortex, or decapsulation after Edebohl's method, if the case be not due to oxalate stone, ought to relieve the hæmaturia and pain.

But there is another class of nephritis that causes both hæmorrhage and pain—"patchy nephritis," I call it. You will frequently find on exposing a movable kidney, whitish patches with sharply defined margins, and these may be solitary or multiple. I have seen as many as six distinct such patches. The cortex is thickened and roughish, and when stripped usually brings away a little of the cortical substance with it, which has a granular looking appearance. In several such cases I have seen the hæmaturia fairly profuse. This condition is probably due to intermittent blood supply to the area, which again is due to the strain of the renal by the movable or kidney vessels. In another class of case, the nephritis seems due to a previous pyelo-nephritis. Here is a case: A man, æt. 25, consulted me for very severe attacks of intermittent hæmaturia, recurring, without any warning, about every three or four weeks for the past seven or eight years. In the intervals he was perfectly well, but his urine always contained large quantities of oxalates. He had some left renal pain, more or less continuous, but it got much worse during the attacks of hæmorrhage. The attacks simulated nephritic colic. On exploration of this case, the kidney was a hollowed-out sack, the ureter was not half its normal diameter, and was implanted into the upper part of the pelvis. This malposition and decrease in size of the ureter evidently produced pelvic distension, which led to the pyelo-nephritis and the entire destruction of the kidney. Nephrectomy cured the case, but he still passes large quantities of oxalates in his urine. We see, then, that this form of hæmaturia may be due to this patchy nephritis, which again is due to (1) infection from lower urinary tract; (2) kink—narrowing of—or (3) mal-implantation of the ureter into the pelvis; or to (4) strain in the renal vessels in a movable kidney, producing an intermittent blood supply. To cure the hæmaturia, then, the exact cause must be ascertained, and we either fix the kidney, remove the narrowing of the ureter by incision and suture at right angles to line of incision, or correct the mal-implantation, and this will usually bring the hæmaturia to an end.

In the remaining causes (a) benign and malignant growth of the kidney, (b) renal calculus, and (c) renal tubercle, the remarks made with regard to the treatment of the hæmaturia in the symptomless variety equally apply here.

In conclusion, gentlemen, I would strongly urge on you the necessity of thorough and accurate diagnosis, before any successful treatment can be undertaken. This, in a large number of cases, can now be successfully accomplished by close inquiry into the history of the case, laying special stress on the onset symptoms, and working up the history, step by step, then by careful examination of the patient, and inquiry into the cardinal symptoms—hæmaturia, undue frequency of micturition, pain, and abnormal characters of the urine, by frequent chemical and microscopic examination of the centrifugal urinary deposits, and by bacteriological examination. By careful and repeated accurate cystoscopy, by direct catheterisation of the ureters, either by Howard Kelly's method, in the female, or by Luy's method in the male, or by ordinary

* April 20th, 1906.—This case was examined four weeks ago, and no calculus found, but there were numerous adhesions at both poles. The kidney was decorticated and returned into the loin. He has lost all pain since the operation, and both albumen casts have so far disappeared from the urine, but whether this will be permanent or not it is too soon to speculate.

cystoscopic catheterisation, by segregation of the urine (Luy's method), and possibly by cryoscopy of the urine, and finally by skilled radiography. By any, or all of these means, a correct diagnosis is made, and a sure basis for treatment is arrived at.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of the journal. The lecture for next week's number will be by Dr. G. M. Variot, Physician to the Paris Hospital for Sick Children, on "The Diagnosis of Pneumonia in Children."

ORIGINAL PAPERS.

THE PATHOGENESIS OF TUBERCLE IN APEX.

By Professor HOFBAUER, M.D.,
Vienna University.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

FROM a very early period in the history of this disease the influence of some germ life has been adduced as the cause and propagation of so intractable a malady. As time went on, susceptibility or the loss of resistance in the tissue itself was blamed more than the bacillus, but how the latter obtains access to the apex of the lung remains for speculation. Why was the lung not as frequently attacked by the microbe in other parts as in the apex? Search was made, but no satisfactory reason could be advanced. Speculation again turned to the anatomical construction of the bronchi, which, by their mechanical action, allowed the germ to be easily carried into the apex where it lay and fructified, destroying the tissue in the immediate neighbourhood. This theory was soon confirmed by physiological experiments showing how substances were easily taken into the apex, but by no physiological effort could it be thrown out again. This explanation sufficed for the time, but another advance in our knowledge upset this theory when it was announced that the germ was non-aerogenic. For a time confusion again reigned, till Rindfleisch earnestly endeavoured to solve the problem by avowing that the real cause was due to an altered condition of the vascular system in the apex. By a method of laborious reasoning, he demonstrated the difficulty the heart had to contend with to pass the necessary amount of blood through this part of the lung. He concluded therefore that the apex in this anæmic condition was exposed to great risk, and therefore could not withstand the ravages of the microbe when it reached this part of the lung. In his arguments the upright condition of the human thorax militated against its proper supply of blood to nourish the part sufficiently.

It was soon discovered that apes, baboons, giraffes, and kangaroos were also frequently the objects of tuberculosis in the lungs, but strange to say, rarely ever in the apex. This again destroyed the cogency of the vascular theory being the correct explanation, as these animals spend the greater part of their existence in the upright position, and must by some means overcome that difficulty referred to by Rindfleisch. However, as no better explanation could be given, a compromise was made, with the arrangement of the bronchi and the deficient vascular supply, which was generously accepted by the profession for a

long time as ample explanation for the apex being the primary source of the disease.

Later, Gessner made another effort to prove that the predisposition of the apex to tubercle was due to a hernial arrangement of the lungs rising up into a narrow part of the thorax, where it was strangulated when coughing or sneezing. He compared the apex of the lung with the physiological action of the gall-bladder and appendix, but differing insomuch as the apex had its vascular supply cut off, thus producing congestion on the part of both blood and lymph.

At this time, Bier had demonstrated that congestive hyperæmia took on the tuberculous condition readier than in the normal state. With these facts disclosed it was impossible to resist the conclusions to be arrived at, although the simile of the gall-bladder and appendix did not meet with universal acceptance as conclusive proof that this was the correct theory. These organs were both free in the abdomen and neither of them was predisposed to tubercle, and therefore gave no assistance to the hypothesis. No anatomical difference could be discovered in the upper lobes of the lung to the lower, whereby a disposition of the one was greater for tubercle than the other, yet it was maintained that condition must exist to favour statistics on the subject, as there was no denying the fact that the apex was more frequently attacked than any other part of that organ.

Within the last decennium closer investigation has demonstrated a physiological difference between the upper and lower part of the lung. In laboratory experiments it is found that quiet breathing only affects the lower portion of the lung—*i.e.*, the upper part of the lung is physiologically dormant during shallow breathing, leaving the upper part quiescent, reducing the pressure and diminishing the blood and lymph supply. When the lungs are well filled and actively engaged, the tissues are more healthy and resistant against disease, which seems to be the explanation of the upper part of the lung becoming the primary seat of tubercle. To accentuate this theory, Sernberg avers that we have not only a congestive stasis in the upper part of the organ, but by the lowered blood supply a sort of atrophy is induced that hastens destruction and favours tubercle. Against this theory we have the argument of why is the whole of the upper lobe of the lung not affected with tubercle instead of the apex alone? If the whole of the upper lobe be badly nourished with blood and the lymph remain stagnant, it is quite reasonable to assume that the entire part of the organ would be equally non-resistant, which is not the case. To meet this it is assumed that the more remote part of the organ, *viz.*, the apex, would be the first to yield to the invading germ. Exner thinks that the ventilation of the lower part of the lung explains the whole case. This is another way of saying the lower part of the lung is more active than the upper.

But we may again ask if this state of affairs exists why do other infectious diseases not affect the upper part of the lung first? Some pathologists do affirm that this part of the lung is so affected.

Grossmann has given us the results of many

experiments carried out in the laboratory to prove that different parts of the lung had different coefficients of ventilation. By inspiration the veins and auricles are emptied and anæmia produced in the lung tissue; in expiration this is reversed and the lung again filled with blood. Grossmann's deductions led him to conclude that the apex of the lung was not subjected to these violent changes and would therefore be more constantly supplied with blood. This is contrary to the theory of perfect rest being the safest for those suffering from hereditary predisposition. It is observed that tubercle in the apex is not so frequent in females as in the male, while costal breathing in females is the only practicable method; thus we have ventilation with freedom from tubercle; but here again Grossmann argues that the whole lung is in a quiescent state and free from unequal pressure that seems to predispose to tubercle in the apex. Against the theory of unequal pressure we have anthracosis regularly distributed throughout the lung both in the human subject and in animals which should not be the case if the theory were true. There is yet another theory put forward by Braun, but the connection is so remote that few have received it with favour. His opinion is that the proximity of the cervical gland to the apex by the intervention of the pleura is sufficient to account for this primary affection of the apex. He attempts to demonstrate this connection by percussion, and the changes that take place in the membrane.

In the face of all these hypotheses Loebl is forced to ask how all these theories have to be reconciled with anthracosis where the fine coal dust is found evenly distributed through the lung tissue if one part of the organ is inert? The answer to this is quite relevant and consistent with the foregoing as those suffering from anthracosis are usually employed in heavy work where deep breathing is practised. Deep breathing alters the circumstances, but it is to shallow breathing the theories apply.

Where the breathing is deep the apex becomes as active as the lower portions, although experiments favour a more active movement in the lung at its base, gradually diminishing as it proceeds towards the apex, and therefore always proportionately less active at the apex even when the lung is most active. Again, females in pregnancy may be illustrated by a case given by Hirschfeld, who found that the tuberculous infection commenced at the base of the lung and not at the apex, because the upward pressure of the uterus impairs the basal movement, and prevents due ventilation of the lower portion of the organ where the bacilli settle and germinate rapidly.

This also disposes of the theory of proximal scrofulous glands in the neck being the primary cause. We may, therefore, accept the diminished aeration of the apex of the lung being the primary cause, although many contributory causes may aid in its completion. If the blood circulation be low and lethargic, and the breathing shallow during the period of bone formation, it is conceivable that the impaired function will reduce the nutrition. The lungs are not exactly bladders or air-bags that fill evenly when inspiration or expiration take place, but are modified by the fibrous septa that affect portions of the lung more adversely than others, and thus reduce the nutrition or even pro-

duce atrophy in one part as a centre of destruction.

If expansion and contraction of the lung be effected during the growth of the bony structure, while the pulmonary function is freely performed, the proper nutrition will be supplied and tubercle at the apex averted.

NOTES ON A CASE OF BRADYCARDIA, WITH ARHYTHMIA AND EPILEPTIFORM FITS.*

By JOHN M. FINNY, M.D. Dub., F.R.C.P. Irel.,
King's Professor of the Practice of Medicine, School of Physic, Irel.,
Physician to Sir Patrick Dun's Hospital, &c.

THE case was that of a seemingly healthy married woman, æt. 42, the mother of three children, in whom there was no evidence of any cardiac or arterial disease, or organic disease of any of the viscera. Her illness began fourteen months before admission to hospital by a fit of unconsciousness in which she fell, which was followed by many similar slight syncopal attacks. She was delivered of a healthy child three months before being under my care. The child died, at the age of seven weeks, of convulsions, and since his death the "weaknesses" had become more frequent—as many as twelve occurring in a day. Her pulse-rate on admission, June, 1905, and all through, was very slow, or infrequent, usually ranging from 20 to 28 in a minute. This slow pulse was unattended by any consciousness on the patient's part, but when the pulse-rate was retarded 6 to 10 seconds she had an epileptiform fit, lasting 5 to 10 seconds, in which her face became at first pallid, with the eyes turned up, then flushed, and with a sigh or hem she came to, her eyes filling up with tears and with an anxious, frightened, and dazed look. Sometimes the attacks were more severe, and there were twitchings of the hands and movements of the legs. A third degree occurred more rarely, when she fell back unconscious and was more confused and dazed after it was over. This last variety was preceded by an aura, as of heat rising from the epigastrium round her heart and up to her head. The worst variety, which came on during the last four days of her life, was sudden and prolonged unconsciousness, in which, to all appearance, she was dead—all the limbs relaxed; no pulse at the wrist for seven minutes; and no respirations for four minutes; and only an occasional flutter of the heart gave any indication of life, and encouragement to the house surgeon to persevere in artificial respiration, injection of strychnine, and oxygen inhalation. This prolonged pulselessness was followed by semitonic spasm, restless and purposeless movements, and cries and groans, and unconsciousness. The attack lasted for four and a quarter hours. On the day but one before death a similar attack occurred, but not so severe; and the last attack occurred twenty-seven hours later, out of the syncopal state of which she could not be snatched.

Remarks.—I may here call attention to the observation frequently repeated during her stay in hospital—that the unconscious attacks were preceded by marked arrhythmia, and claim that their cause lay in the cerebral anæmia, produced by the long periods of ventricular arrest, and not

* Read before the Section of Medicine, Royal Academy of Medicine in Ireland, March 30th, 1906.

that the epileptiform attack caused the arrhythmia or heart block. Simultaneous tracings of the jugular vein and the radial artery made by Professor W. H. Thompson gave undoubted evidence that the tracings of the jugular vein were three times as frequent as those of the radial artery. I would emphasise the advantage we had obtained by the X-rays, in demonstrating that for each beat or shadow of the ventricles three auricular shadows could be counted.

In discussing the want of agreement between the auricular and the ventricular systoles, the myogenic theory of Gaskell of the heart's movements and rhythm was referred to, and the term "heart block" explained. The author's case clearly demonstrated that, for some reason unknown, the contracting muscles of the auricles did not convey their stimulus to the muscles of the ventricles except once in three or even ten contractions. It also showed that the want of agreement of the pulse and auricular contractions was not explainable on the theory that the left ventricle did not contract while the right did—hemisystole—a theory propounded by Broadbent. The principal theories of the causation of the condition exhibited in this case (to which the term "Stokes-Adams Syndrome" is more or less applicable) were passed in review, but were considered as being wanting in precision in the case recorded, however justified they may be in cases of senile heart with arteriosclerosis.

SOME FUNDAMENTAL CONSIDERATIONS CONCERNING DIET.*

By WILLIAM RUSSELL, M.D., F.R.C.P. EDIN.,
Assistant Physician, Royal Infirmary, Edinburgh; Lecturer on
Pathology, Medical College for Women, Edinburgh.

INACCURATE diagnosis of the dyspepsias and their haphazard treatment is responsible for part of the opprobrium still attached to medicine in the minds of a considerable section of the public. It is not to be denied there is some reason in this, for the estimate of medical wisdom is determined by the knowledge and skill of individual practitioners and the newer knowledge of the digestive processes and of foods has not yet been widely taught, nor has it been universally assimilated by teachers themselves. In no department is it more necessary than in this to have a clear and accurate knowledge of normal function, of the needs which it is the duty of function to supply, and of the material suitable for function to deal with. Knowledge of digestive processes has in the past been crude, ideas regarding diet must be held to have been extraordinarily inaccurate, and ignorance of the food values of many ordinary foods very great.

Taking into consideration, in the first place, the question of the kind of food required to maintain strength and vigour, enormous changes have taken place in the food-habits of the country and the highland people of Scotland. They must be well within the knowledge of many of our members. My own recollections I have checked by conversing with people older than myself, and who were probably in a position to have more accurate knowledge than myself on the matters referred to.

The recollections which interest me most bear upon the habits of the farm-servant class—married men with families, and working on large arable and pasture farms. These men had a free house, and free fuel was supplied by the peat stack. They had an allowance of oatmeal and of potatoes, and a cow was provided as a milk-supply for one or more families. Oatmeal, potatoes, and milk formed the great bulk of the

family food. In the part of Scotland to which I refer this was in some cases supplemented by a limited supply of herrings, cured and salted by the female head of the family. Occasionally there was a piece of cured pork. The ordinary daily dietary consisted of oatmeal porridge, or oatmeal brose, three times a day; an occasional meal of potatoes and herring supplemented this and provided some variety. In some cases the potatoes and herring, or even pork, formed more regular part of the daily menage. There might sometimes be eggs, and cheese might be made from some of the milk.

The bothy hands lived almost entirely on oatmeal, in one or other form, and milk. In Perthshire the farm hands lived in much the same style—indeed, I am assured that a Perthshire ploughman lived on oatmeal porridge, or brose, with milk. This was his food morning, noon, and night—for breakfast, dinner and supper.

As regards my personal experiences in the matter of food, children had porridge and milk morning and night, and did not expect, nor, so far as I recollect, did they want anything else. Dinner was in the main a fish or flesh meal with potatoes, barley broth and nutritious soups being included in this. It may be stated that the supply of milk was distinctly limited, for in those days it had to be sent for to some farm not too far away, and, although paid for, it was supplied almost as a favour. The milk-cart had not appeared in these regions at that date.

The meaning of these examples is that the kind of food sufficient for the maintenance of an active adult life may be extremely simple. This is an elementary truth that requires to be repeated with much insistence to-day, presumably because our social and domestic arrangements are so much more elaborate and complex that we hardly realise that our elaborate and complicated culinary arrangements are *necessary* only for the perverted or the jaded palate. We have come to regard a certain kind of food as essential to modern comfort, as the knife and fork are; not only essential to comfort, but necessary for the maintenance of that virility of mind and body which are rightly regarded as necessary for the strain of life, particularly in our large commercial and industrial centres. There can be no question that the *general* idea is that animal foods in abundance are absolutely necessary for the production and maintenance of this high degree of virility; this idea has permeated all classes, and has saturated the minds of the high and the low, the rich and the poor. The average three meal-a-day person considers that he in no way oversteps physiological requirements if his breakfast consists largely of proteid with a very moderate quantity of bread; his midday meal again proteid, with bread or potato; and his evening meal again largely proteid. Under the term "proteid" is, of course, included eggs, fish, and flesh of all kinds, and we have only to consider the diet of those around us to recognise the extent to which proteid enters into our present method of feeding. The amount of other food consumed varies greatly in individual cases. Some eat largely of bread in one form or another; some eat freely of potatoes and vegetables; and some eat what are known as "milk puddings," and which contain, in addition to milk and eggs, some one of the carbohydrate foods as sago, rice, tapioca, &c. It may, I think, be asserted, that all these are widely looked upon either as not belonging to the essentials in a meal or as occupying an entirely subsidiary place to the proteids. Let this be illustrated thus. Take potatoes—they are eaten with meat usually in very small quantity. Who, save the poor of Ireland, thinks that potatoes might be the main item for a meal, with milk, or a salt herring as kitchen, and yet this would constitute a physiological meal, and such a meal as appears to have been very common in Scotland in past times. There are traditions in Edinburgh which tell of Highland students living and flourishing mainly on oatmeal, potatoes and cheese supplied from the not overfilled

* The Caledonian Medical Journal, April, 1906.

home stores. From the physiological standpoint, these traditions are not necessarily mythical.

Further facts in support of the contention that extreme simplicity in diet is not inconsistent with the performance of ordinary functions, and some degree of activity, might be found in various directions. I heard a description of one of the late famines in India from a man who had worked through it, and he stated that the lowest and poorest caste, in the district in which his experience was acquired, lived on one of the poorer cereals, which was made into a cake mixed with some herb; that this cake was the only food those people had, and they had only one meal a day. That was their normal food supply, and, as he pathetically put it, take that away and famine to those people meant that they had no food of any kind whatsoever. If this story is correct, and I have no reason to doubt it, it shows how very meagre the supply of food may be without leading to complete physical inability. This was not a story of isolated individuals, but of an entire class of people, a section of the community under British rule in India.

The popular belief has been that only peoples who ate largely, or, at least, considerably, of flesh were physically strong, capable of physical effort, of prolonged toil, and could manifest endurance. The evidence of this, in most persons' minds, was found in the physique and character of Oriental peoples, particularly in the rice-eating peoples of India and China. The entrance of Japan into European politics in the East, and the physical and moral qualities which the Japanese have so strikingly displayed in their armed contest with a European power, may be said to have produced in our minds a somewhat startled sense that our ideas and standards have been totally wrong, or, at least, grossly inaccurate. The belief that victory and endurance belonged to the flesh-eating peoples was deeply ingrained into our minds, and it was confidently held that free flesh-eating was essential for the manifestation of prolonged physical and mental effort. Not only was this the general conception in regard to material result, but flesh-eating had actually become a standard of what was popularly called "comfort." The amount of flesh consumption increased with the increase in comfort in housing, in clothing, and in other directions as well. Official returns showed that, with increase of wages, flesh consumption proportionately increased. I imagine that this was not from any great craving for flesh food, but, to a very large extent, was the result and outcome of the popular and general idea, such as has been indicated. The popular idea was the result of ignorance and of wrong teaching. Upon whom the responsibility for the wrong teaching lay need not be inquired into; the responsibility for the belief and habits of a generation belong, seemingly, to the generation, not as individuals, but as a whole, and it is often merely a phase in the movement towards a goal which is neither seen nor even sought for. It would be interesting to look into the question of the relation between increased material prosperity, as measured by an increase of money in the hands of the community, and the amount of this new wealth which different peoples and nationalities expend on augmenting and elaborating their feeding arrangements. Does the French peasant depend upon the baker's and the butcher's van as many of the peasantry or farmservants in some parts of Scotland depend? Do the miners of Germany and Austria spend money on what they eat and drink in the same proportion as they do in some districts in Scotland? Are increased wages to be regarded largely as a stimulus to gluttony and self-indulgence, and the very cheapness of plain food a reason for pampering the palate with more expensive articles? Is the object of feeding, the supplying of the body with necessary sustenance, or the providing of the palate at stated periods with articles to titillate its nerve-endings? although the latter of these propositions is applicable to individuals in all classes, from the labouring class upwards, there are others whose dietary has been de-

termined by what has been referred to as bad education and inaccurate knowledge, or pure ignorance. It is this class who may be expected to be benefited by instruction in more modern knowledge—showing them what the true needs of the body are, how these can be supplied, and what the true food values of the more common foods are. With this large class, the ordinary feeding arrangements are really due to the traditions of their class, or if they are hardly deserving of the measure of dignity associated with the idea of tradition, it may safely be said that they are the result of custom which has grown up into its present form for want of proper guidance and of accurate knowledge.

To estimate aright the question of diet, it is necessary to differentiate clearly between what is necessary for the maintenance of the adult body in health and vigour on the one hand, and, on the other hand, all that goes beyond that and which belongs, therefore, to the category of luxuries. The necessity for this distinction cannot be too strongly insisted upon.

The flavour of food and its attractiveness to the palate is considerably mixed up with the foregoing question, and yet the two factors ought to be kept separate in our minds. The flavour of cooked food depends largely upon the mode of cooking which has been employed, and it is this artificially produced property which makes flesh not only eatable but stimulating and attractive to the sense of taste. The flavours of cooked flesh are, on the whole, stronger than those of other kinds of food, and their use, doubtless, brings the palate into a condition in which less strong flavours cease to be appreciated. There is, however, a further side to this, and that is, that the knowledge of cooking in general is of the most elementary kind, while ideas concerning the use of cooking vegetable and cereal food is of the crudest possible description. As a consequence of this lack of skill vegetable and cereal foods are often presented in a form or in a condition in which only the strongest sense of duty or impelling hunger would ever ensure their consumption. Amongst vegetables it is only necessary to single out the potato to support the foregoing statement. Compare the waxy-looking insipid article often offered to you at private or public tables with what the potato can be when properly cooked in its skin. Instead of the damp, sodden article it is dry and floury, and is as different in flavour from the badly-cooked article as to have no resemblance to it. The well-cooked potato might well be given a place to itself as a separate course in a scientifically arranged menu; and the potato so treated would not have to be so frequently excluded from the diet of the dyspeptic as is at present necessary. Many persons have experienced the joy of eating the roasted potato of the "hot-potato man," and have found it, with the addition of salt, or a piece of butter and some milk, an ample repast. And yet comparatively few cooks or housewives have acquired the elementary art of roasting potatoes aright. When we turn to look at cereals and their use in the domestic economy, much the same condition of matters is found. White bread made by the baker is in almost universal use, and few housewives supplement it or vary it by home baking; variety is found in the relatively expensive small breads also provided by the baker.

If we consider the position of the best of the cereals, namely, oats, the position is still worse. Very few cooks can make oatmeal into cakes that are in the slightest degree attractive to the average palate, and yet oatcakes can be so made as to be acceptable to the most critical. As for oatmeal made into porridge, the product under which this name may be presented to you from the kitchen of a private house or at the breakfast table of a London hotel is food fit only for hens or pigs. And yet oatmeal porridge can be so prepared and cooked as to bring out all the rich nutty flavour which characterises oats above all other cereals, and makes them not only a wholesome but a delicious food.

Mention may be made of one other cereal, namely, vice. It is well known that it is the staple food of

millions of people in our Indian Empire and in the further East, and great quantities are imported into this country, but much of it—what proportion of the whole I do not know—is used to make starch. It is, however, also widely used for making puddings; and boiled rice and milk is known in the nursery and in public institutions. Plain boiled rice is never used as the staple and chief part of a meal, and, when it is provided in lieu of vegetables or potatoes, it is often either insufficiently cooked or served as a sloppy pul-taceous mess. Rice, with some curried fish or vegetable to serve as kitchen to it, has no place with us corresponding to the place it has in the East. This is not altogether a question of cooking, but a further illustration of the fact that all this class of food has been given a second place in our feeding arrangements, the first place having been given to animal foods. So extravagantly has the public mind been turned to these that potatoes and cereals are largely regarded as mere accessories or garnishing; they have been given the place that ought to be held by the latter, and which the latter ought to occupy in a scientifically adjusted dietary.

FOOD CONSTITUENTS.

The food constituents required by man are comprised in the four great groups of (1) proteid or albuminous substances, (2) fats, (3) carbohydrates, and (4) salts.

Proteid.—The first of these, the proteid or albuminous substances, are present in varying proportions in vegetable substances as distinguished from animal, but it is from the latter, namely, animal substances, that we obtain the great part of this class. Animal substances are very rich in proteid material. It forms a large part of the nutrient elements in the flesh of animals, of birds, of fowls, of fish, of eggs, and of milk.

The term "animal food" is often used to distinguish the flesh of four-footed animals, while the members of the feathered tribe are excluded. The term *proteid food* is more comprehensive, and it is the one which requires to be used in the consideration of man's requirements. People who eat freely of the flesh of birds and of fish assure you that they take very little "animal food." What they mean is that they do not eat beef, mutton, or pig in any form. It is further to be borne in mind that eggs and milk are animal products, and are rich in proteid.

Many members of the vegetable kingdom used commonly as food also contain proteid, although in a relatively small proportion as compared with flesh of all kinds. The vegetables most rich in proteid are the legumes, as lentils, peas and beans. The cereals contain a varying proportion of proteid, the poorest being rice, while oatmeal is the richest by reason of its mode of preparation. The tubers, as potatoes, contain but a small proportion of proteid.

Fat.—The fat of man's food is derived mainly from the animal kingdom. The cereals contain a certain proportion of fat, but so small as to constitute an insignificant part of the total fat commonly consumed. Animal fat is present in flesh of various kinds, and it thus forms more or less a constant constituent of flesh food. With many persons, however, the greater proportion of the fat consumed is supplied by butter and milk.

Carbohydrates.—The carbohydrates are the starches and sugars, and are obtained from a large number of vegetable substances. At the head of the list are found the cereals, comprising wheat, oats, barley, rye, rice, and Indian corn. In all these, the main nutrient element they contain is starch. They individually also contain a varying proportion of proteid and of fat. The next great source of carbohydrates is potato. Then come arrowroot, sago, and tapioca; while a number of other substances on the market, and more or less widely used, are prepared by special processes from the cereals, and largely from wheat or Indian corn.

Salts.—Salts are present in both animal and vegetable food substances; but certain staple articles of food are

very deficient in this respect, and from amongst them ordinary white bread may be singled out as a striking example.

THE USES OF THE VARIOUS FOOD CONSTITUENTS.

With reference to the uses to which the constituents of food are put, it is imperative to have correct ideas regarding the part they respectively play in the vital economy before any attempt is made to arrange the diet of our patients with any reasonable expectation of success. Taking the *proteid* or *albuminous* first, they are necessary for the supplying of material for the growth of the growing and enlarging body of childhood and youth, while in adult life, with its fully grown body, they are required for the repair of the waste, consequent upon, and due to, vital activity. Formerly, it was thought that the measure of physical activity determined the measure of tissue waste, but this has been found not to be exactly the case. The waste in the tissues is represented in the urine as urea, and it is not found to increase in proportion to the amount of muscular work done. There is, of course, a measure of waste; all that is sought to insist on here is that it is not as great as used to be thought. The waste has to be replaced from the albuminoid or nitrogenous constituents of the food, so a sufficient supply of these is absolutely essential to the maintenance of body-weight and vigour. Beyond this amount, however, there is no need of further proteid; in fact, any further amount cannot be used, and has to be got rid of. The recognition of this fact is of supreme importance when dealing with disordered conditions, and yet it has only comparatively recently been recognised. It is still very far from being adequately accepted, acted upon, and applied to the treatment of many conditions where its application would be invaluable. The matter is even more important than this. It would appear from recent American investigations that this extra and unnecessary amount of proteid is not merely to be regarded as waste or unnecessary material which can be easily excreted, but that for its chemical transformation from the original proteid into the excretory product urea, much unnecessary strain and stress are developed, and energy expended without any compensatory benefit to the body. It is maintained that not only is this the case, but the energy thus called forth is detrimental and injurious; that it can be conserved and directed into infinitely more profitable channels in the direction both of physical and mental activity. If this be approximately correct, and I have little doubt that it is, it becomes at once apparent how immensely important the matter is, especially in adult life, and still more so after middle age. The effect of an excessive proteid supply will be again referred to.

Carbohydrates and fats may with advantage be considered jointly. They are commonly regarded and referred to as "heat-givers" or "energy-producers." It will, however, lead to a clearer understanding of the value of these substances if they are regarded as "proteid-sparers," or "proteid-savers." The explanation of these terms may be stated thus:—During the physiological activity of cells the cell can use up carbohydrate material, burning it up as in a miniature furnace, thereby saving and conserving its own more highly organised proteid material. In this burning-up process heat is produced, and it is upon this process that the temperature of the body depends. The combustion of carbohydrates may, however, also be regarded as facilitating the metabolic process in the cells, and furthering, possibly in a very important measure, the removal of the waste or excrementitious products which result from cell activity. In the performance of this very important *role* the carbohydrates and fats are interchangeable. The fats, indeed, act more powerfully than the carbohydrates, in something like the proportion of 2½ to 1. In the ordinary methods of feeding, however, both carbohydrates and fats are used, and the former in much larger amount than the latter. In the Arctic regions fat is mainly used. If the supply of carbohydrate or fat is in excess of what

is physiologically required, it tends to be stored in the body as fat, leading to ordinary obesity.

Salts.—The salts are also of vital importance, but it is not proposed to deal with them at present.

THE REQUISITE PROPORTIONS.

We are thus naturally led to the consideration of the proportions of the various food elements which are requisite for the upkeep of the body in a vigorous condition. The figures of various authorities might be given, but we may meanwhile use Church's.

In these the ratio between albuminoids and carbohydrates, including fat, ought to be 1 in $4\frac{1}{2}$; that is to say, for each ounce of albuminoids present in the daily food there should be $4\frac{1}{2}$ ounces of carbohydrates, including fat.

From tables published by various authorities it will be seen how very superior in proteid and fat oatmeal is to wheat-flour, rice, and potato. It will thus be apparent that certain plain and cheap articles of food can be combined, so as to constitute a strictly scientific dietary. Further, that various dietaries to which reference has already briefly been made supply, notwithstanding their simplicity, all the essentials for maintenance and vigour. The oatmeal and milk of the Scottish farmservant of former times, the potatoes and flesh or fish, either fresh or cured, the bread and cheese of the labourer of to-day and of the past, all fall into this category. The rice, vegetables, and fish of the Japanese fulfil the requirements. The rice and curry of India may also do so, for the curried accompaniment may be rich in proteid, although not always so. In most of these the proteid necessary for repair and the carbohydrate and fat necessary for the production of energy are abundantly present. This seems to me, however commonplace it may appear to many, to be very imperfectly realised. I am not specially concerned at present with the question of flavour, but it can certainly be insisted upon that oatmeal, fish, bread, cheese, and milk are all capable of being presented in a manner that, if ignorant prejudice were excluded, would be acceptable to the average palate. As has been already indicated, it is when the physician seeks to regulate diet on the broad principles of physiological requirement that he realises how deeply rooted the prevalent customs are in people's minds. While I have taken the above as examples of simple and yet correct relations, it must not be thought that it is necessary to confine ourselves to the particular substances specified above. The point I seek to make clear is that the popular custom has put proteid out of its scientific relation to the other food ingredients. So much has this been impressed upon me that I am disposed to think that the extraordinary prevalence of constipation amongst all classes must be largely due to the prevailing food habits. This prevalence of constipation is an important one from the public health standpoint, for it, too, leads to vessel and tissue changes sooner or later in a large number of persons, and leads to great loss of energy and of working power in multitudes of men and women. There are probably other factors in operation as well as the factor of bulk, for it can readily be assumed that the great difference in chemical constitution between animal and vegetable foods becomes a very potent factor in determining this habit.

It must, I think, be acknowledged that in a proportion of people, how large or how small it is impossible to say, all excretory functions are so efficiently performed that the effects we have referred to are not readily recognised, and that it is only in advanced life that the vascular and other changes are brought under our notice, and that we recognise in them the cumulative though slow operation of the causes under consideration. This point is of practical importance at the present time. On the question of diet for man, there are always persons holding extreme views, who preach their gospel out of season as well as in season, and who, by their fanaticism, impede the acceptance of new knowledge. It is only necessary to mention the fanatical vegetarian in proof of this statement. He is often a person who almost, if not altogether,

regards the eating of flesh as sinful. If he does not go quite so far, he is strong in the denunciation of the habit as injurious to the health of everyone who indulges in it. There is no doubt that, as has been said, many persons have excretory functions in such perfection that they easily get rid of surplus proteid. On the other hand, it is equally certain that the great majority of people who are in comfortable circumstances eat proteid beyond their physiological requirement, are not endowed with good excretory functions, and suffer accordingly. That the consumption of flesh in physiological quantity is universally hurtful is not a sound proposition. What is required is reform on true physiological lines, not revolution based on the painful experiences of pathological types.

CLINICAL RECORDS.

CASE OF FIBROMATOUS TUMOUR OF THE CAPSULE OF THE KIDNEY.

By N. H. HOBART, F.R.C.S.,
Surgeon to the North Infirmary, Cork.

MRS. C., æt. 26, primipara, was delivered on February 4th, 1906, labour normal. Three days after delivery, a tumour about the size of a small orange was noticed on the right side of the abdomen, at the level of the navel. It was tender, with smooth surface and of firm consistency. She had not noticed any tumour before or during pregnancy, but had had pain and tenderness during the last three months. On February 28 I saw patient for the first time, and found a large, oval, smooth tumour extending from the right iliac fossa to about two inches above the umbilicus. I thought it was a tense cyst. On March 4th, as the temperature had been about 102° F. for some days, I aspirated, and withdrew a small quantity of dark serum. On March 5th I opened the abdomen by a median incision, the tumour covered with peritoneum presented. A trocar was used, and about a quart of dark fluid came away. The peritoneal covering was then freely incised longitudinally and the lower pole shelled out, but the upper pole could not be stirred and the incision in the belly wall had to be lengthened by three inches. On freeing the upper portion, the kidney was exposed, and it was seen that the capsule of the tumour was firmly attached to the capsule of the kidney. As several large vessels from the cyst wall were seen apparently entering the renal vessels, and as the kidney itself seemed not to be involved in the growth (about the malignancy of which there was some doubt), it was decided to clamp the cyst wall as close to the kidney as possible. This was done, and the clamp allowed to remain *in situ*. The retro-peritoneal flaps were then united by a continuous catgut suture, any redundant tissue being removed. The cæcum and ascending colon were attached to the inner portions of this layer. The united edges were then sutured to the parietal peritoneum, and the wound as far as the umbilicus sutured in two layers. The peritoneal covering of the upper portion of the cavity was then united to the upper portion of the abdominal wound, which was left unsutured. The cavity was packed with a Mickulitz bag, by the side of which the handles of the clamp, and those of two pressure forceps, which had to be applied to the kidney where it was accidentally wounded, were allowed to emerge. The solid portion of the tumour was about the size of a small adult head. During the operation patient became greatly collapsed, and two pints of saline were injected subcutaneously under the breasts. The Mickulitz bag and pressure forceps were removed in twenty-four hours, and the pedicle clamp twenty-four hours later. The patient made an uneventful recovery. Only a small quantity of clear serum now discharging from the sinus.

Dr. Moore reports that the tumour is a pure fibroma of the capsule of the kidney, and that there is no trace of sarcomatous tissue in it.

OPERATING THEATRES.

ST. BARTHOLOMEW'S HOSPITAL.

TENDON ANASTOMOSIS.—Mr. McADAM ECCLES operated on a boy, *æt.* 5, with localised infantile paralysis. The left leg was affected, the patient having pronounced talipes varus, with a slight degree of equinus. On examination of the muscles by the make and break of the constant current, it was found that there was only reaction of degeneration in the peronei, longus and brevis, and that all the other muscles responded normally. Mr. Eccles therefore looked upon the case as a very favourable one, in which an anastomosis might be carried out.

Accordingly, after very careful preparation, an incision was made on the posterior aspect of the leg towards its outer side, extending for about two and a half inches. Through this incision the tendons of the peronei, and the outer part of the tendo Achillis were exposed. The tendon of the peroneus longus having been lifted out of its sheath, a portion of the tendo Achillis was obtained in the following manner:—An incision was made in the tendon, so as to split it vertically, separating off one-third of its breadth, and close above the insertion of the tendon this strip was divided transversely. Next this portion of the tendo Achillis was passed through a small longitudinal slit in the tendon of the peroneus longus, and firmly secured by fine silk stitches. The wound in the sheath of the peroneus longus was carefully sutured over the tendon anastomosis, and the superficial wound was closed.

Mr. Eccles remarked that the cases of infantile paralysis, in which tendon anastomosis or tendon transplantation was feasible, were not very many. The object of the operation was to diminish the action of the opposing active muscle and to induce some action in the paralysed muscle. In this instance these conditions were eminently fulfilled, because a part of the tendon attached to active muscles was engrafted into the tendon of a paralysed muscle. Mr. Eccles considered that the passing of the strip from the active muscle through a vertical slit in the passive muscle, before the two were held together by sutures, was the best method, as it ensured the greatest possible chance of firm union. Asepsis was an absolute essential for success. The wound healed soundly, and the patient was allowed to walk a fortnight later, when it was found that the anastomosis had been instrumental in diminishing the amount of varus to a very appreciable degree.

CHELSEA HOSPITAL FOR WOMEN.

OVARIOTOMY FOR A PAROVARIAN CYST.—DR. ARTHUR GILES operated on a single woman, *æt.* 31, who had been admitted as a case of urgency. When he first saw the patient with Dr. Withers Green, she was suffering from acute abdominal pain, which had been going on for several days. For three or four days she had been vomiting almost incessantly. On examination the abdomen was greatly distended by a large, tense, cystic tumour. On vaginal examination, the uterus was of normal size, drawn up behind the pubes, and the pouch of Douglas appeared to be filled up by an extension of the tumour. The diagnosis arrived at was: ovarian cyst with a twisted pedicle, and in view of the urgency of the symptoms, it was decided to operate as soon as possible. She was admitted the same day into the hospital, and the operation was performed in the evening. On opening the abdomen, the tumour proved to be a

parovarian cyst situated in the left broad ligament; it had stripped off the peritoneum and the meso-sigmoid in such a way that the bowel was spread over the surface of the tumour. The peritoneum was incised and an endeavour was made to enucleate the tumour; this proved to be a matter of very great difficulty, because the cyst had burrowed downwards between the vagina and the rectum, and the lower end of it could hardly be reached. Eventually, by emptying the cyst and making strong traction on its wall, so as to raise the whole pelvic floor, separation was effected. A large raw surface was left which was covered over as far as possible by suturing together the cut peritoneal edges. A rubber drainage tube was passed down to the bottom of the sac, and the abdominal wound closed, after shutting off the sac from the general peritoneal cavity by a process of marsupialisation. Dr. Giles said that it was very unusual for a parovarian cyst to cause symptoms simulating the torsion of an ovarian pedicle; as a matter of fact, the symptoms in this case were virtually those of acute intestinal obstruction, except that the bowels had acted. Another remarkable feature of the case, he pointed out, was the manner in which the cyst had burrowed downwards. He had not infrequently seen a parovarian cyst dissecting the peritoneum upwards, but he had neither seen, nor read of, a case in which such a cyst separated the vagina from the rectum. The dissection here was so complete that the left ureter was freely exposed for a distance of four inches, lying loose over the brim of the pelvis; in such circumstances the ureter was naturally exposed to great danger during an operation, but fortunately in this case it appeared to be undamaged. Such a large raw surface as was presented in this case was, he remarked, a source of great anxiety to the operator, because it might easily lead to adhesions and consequent intestinal obstruction. The only way to deal with the condition was to bring the peritoneum together in such a way that the raw surfaces were all contained in a sac shut off from the general peritoneal cavity and separately drained. When this drainage was effected through the abdominal wound the process was known as marsupialisation of the sac.

Society for Relief of Widows and Orphans of Medical Men.

At a quarterly meeting of the directors of this Society, held last week, Mr. Alfred Willett, F.R.C.S., vice-president, in the chair, it was shown that since the last meeting three widows, annuitants of the charity, had died; one had received the sum of £697 in grants, another £372, and the third £651 10s. Their husbands had each paid in subscriptions only £52 10s., being the amount representing twenty-five years' subscription, after paying which no further payments were required. The death of one of the directors was reported. An application for relief was received from the widow of a late member, and a grant at the rate of £50 per annum recommended. Ten letters had been received since the last Court, from widows of medical men, asking for relief, but this had to be refused, owing to the fact that their husbands had not been members of the Society. Proposals for membership from three medical men were considered and the three were duly elected. The amounts received by the annuitants, compared with the aggregate sum of subscriptions, are striking evidence of the great advantages of this Society, which cannot be too strongly urged upon the members of the medical profession, resident within twenty miles of Charing Cross. Full particulars will be sent on application to the secretary. The annual general meeting will be held on Thursday, May 3, at 5.30 p.m., at the offices of the Society, 11, Chandos Street, Cavendish Square, London, W.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, MARCH 30TH, 1906.

GEO. PEACOCKE, M.D., in the Chair.

KERATOSIS.

Dr. W. J. THOMPSON exhibited a case of the above which had been under his care. The patient's personal and family history was good, and before Christmas he was quite well. Then the palms of his hands and soles of his feet became rough, thickened, and swollen. The inside of the mouth became very much swollen, and the gums covered the teeth. His eyes were bloodshot; the skin thickened in the axilla, and about the elbows and chest. All the openings of the body, ears, eyes, &c., were swollen; that of the nose sometimes became ulcerated and painful. His organs, nervous system, reflexes, and thyroid were normal.

Dr. WALLACE BEATTY considered it to be an example of acanthosis nigricans, and exhibited a plate illustrating the affection.

Dr. W. J. THOMPSON said the patient was under thyroid treatment for the past three weeks with considerable benefit. He added that the man's genital organs were completely atrophied.

BRADYCARDIA, WITH ARHYTHMIA AND EPILEPTIFORM FITS.

Dr. FINNY read notes of a case of the above, which had been under observation for nine months, and which ended fatally after very severe and prolonged fits of syncope. These notes will be found under the heading of "Original Papers," on page 442.

LEUKÆMIA.

Dr. PARSONS read notes on a case of the above. The patient, a man, æt. 38, was admitted to the Royal City of Dublin Hospital on September 8th, 1905, complaining of swelling in his abdomen, shortness of breath, and palpitation of the heart. On examination the spleen extended three inches to the right of the umbilicus, and as low down as the anterior superior spine of the ilium. There was practically no enlargement of the lymphatic glands, and no tenderness on percussion over the long bones. The blood-count made on September 21st showed red blood corpuscles 3,070,000, white blood corpuscles 260,800, and hæmoglobin 57 per cent. A differential count of the white blood cells disclosed 85 per cent. of myelocytes and 20 per cent. of polynuclear neutrophiles. The changes in the blood counts were indicated on large diagrams specially prepared. The diminution in the size of the spleen was demonstrated by photographs, and detailed observations on metabolism were discussed. When discharged on March 14th, the spleen had greatly diminished, the red blood corpuscles had increased to 3,900,000, and the white blood corpuscles had fallen to 9,000. The myelocytes were present in only 8 per cent. of the total leucocytes. The treatment consisted of arsenic, iron, phosphorus, and the X-rays.

Dr. FINNY said the paper gave rise to a very interesting question—viz., What value was to be given to the X-ray treatment in this affection as regarded the red corpuscles and the size of the spleen?

Dr. C. M. BENSON said he was associated with Dr. Parsons in this case. The patient did not suffer from any nausea or giddiness. The dermatitis was slight after the X-ray treatment. The X-rays were said to have an antiparasitic action, and to cause partial destruction of the white cells without affecting the red corpuscles.

Dr. WATSON said he saw some cases treated in London a few weeks ago. The dermatitis did not cause much concern, although in two or three cases it seemed to have been very severe after the application of the X-rays. As regarded the action of the X-rays

on the spleen and other glands, he believed that a gland, after prolonged exposure to the rays, would become fibrous.

Dr. A. R. PARSONS, in reply, said that the dermatitis resulting from the X-ray treatment gave rise to no inconvenience, while the size of the spleen and number of white cells were diminished.

GLASGOW EASTERN MEDICAL SOCIETY.

MEETING HELD WEDNESDAY, APRIL 18TH, 1906.

The Vice-President, Dr. BARRAS, in the Chair.

TREATMENT OF FRACTURES OF THE HUMERUS.

Dr. JOHN GRANGER showed two cases of fracture of the lower end of the humerus. The fractures were treated, first by reducing and coaptating, under chloroform, the broken ends of the bone, and then fixing the forearm, acutely flexed, to the upper arm. The patients had perfect use of their arms, and there were no joint adhesions.

Dr. JOHN PATRICK showed a case in which, when the jaws were locked, the upper and lower molar teeth met first, leaving a considerable space between the upper and lower incisors and canine. There was difficulty in taking solid food. The front teeth were condensed very much together, and the hard palate deeply recessed. The question of congenital syphilis was raised.

Dr. J. W. MATHIE read notes of a very interesting case of

ICTERUS NEONATORUM.

The baby gradually pined away, and died on the thirteenth week. The urine was saffron-coloured, and the stools of a putty character.

Dr. ANDERSON, who performed the *post mortem*, demonstrated sections of the liver. The bile ducts had been the seat of cirrhosis, and there was likewise a catarrhal state present. The liver was engorged, and the hepatic cells bile-stained.

CORK MEDICAL AND SURGICAL SOCIETY.

GENERAL MEETING, HELD MARCH 28TH, 1906.

The President, Dr. R. P. CROSBIE, in the Chair.

Dr. P. T. O'SULLIVAN read notes of two cases of poisoning, one by strychnine, the other by phosphorus. In the first case he had occasion to order a strychnine mixture for D. C., æt. 62, who had suffered from diabetic glycosuria for four years, and gave him 2 drachms of liq. strychninæ, B.P., in a 4-ounce bottle; dose, one teaspoonful (by measure) in a wineglassful of water after meals. Patient, whilst writing letters after dinner, poured out a wineglassful of the mixture, and drank it off. An hour later, getting alarmed, he sent for Dr. O'Sullivan, who found him in a state of great excitement, but showing no symptom of poisoning except some slight trembling of the leg muscles. He watched him for an hour, and saw him frequently during the evening, but no other signs appeared, and next morning he was all right. Commenting on the case, Dr. O'Sullivan said patient had swallowed 3.5 gr. of strychnine, and there were instances where $\frac{1}{4}$ gr. had proved fatal. He thought (1) that the strychnine was bad; (2) the full meal prevented the rapid absorption if the drug; (3) that owing to the advanced diabetic condition the drug was tolerated in larger doses than in the normal subject. He said his reasons for masterly inactivity in treatment were (a) absence of symptoms; (b) if the alkaloid were absorbed the treatment would be merely symptomatic, and one could not hope to eliminate the poison.

In the case of phosphorus poisoning, that of a child that swallowed the heads of several matches, there was jaundice, with enlargement and tenderness of the liver. The stools were clayey, and smelt of phos-

phorus, and in the dark showed faint phosphorescence. The urine was scanty and bile-stained, and showed small trace of albumin, but no leucin or tyrosin. Patient was restless, and did not sleep at first, but afterwards got stupid and had to be aroused. There was no trace of bile in the stools for twenty-nine days. Patient made a good recovery, being carefully nursed and treated expectantly.

A discussion followed, and the general opinion was that the pharmacopoeal dose of strychnine was too small, and reference was made to the huge doses given hypodermically in shock. Referring to the phosphorus case, Dr. PEARSON stated that the authorities considered jaundice a sign of fatal import.

Dr. N. J. HOBART then read notes on a case of Fibromatous Tumours of the Capsule of the Kidney. They appear in another column.

Dr. HOBART next showed a hat-pin which he had removed from the urethra of a man, æt. 22. He first tried to secure the point; this failing, he pushed the point through the skin until the head alone remained in the urethra; next altering the direction, he pushed the pin out through the meatus.

Dr. HOBART also read notes of a case of perforated gastric ulcer treated by laparotomy. The symptoms were great pain, collapse, dyspnea, rapidity of the pulse and straining. The liver dulness had not disappeared. He operated four and a half hours after the onset of the symptoms, and found a hole $\frac{1}{4}$ -inch. in diameter in the anterior wall of the stomach. Having mopped up the extravasated fluid, he stitched up the rent with two layers of Lembert's suture, draining with a wick tube. Patient made a good recovery.

CASE OF EMPYEMA TREATED BY ESTLANDER'S OPERATION.

Dr. CORBY read notes of this case, and showed the patient. J. D., æt. 26, a man of phthisical appearance, was transferred from the medical wards to his care suffering from a localised right side empyema. He did a thoracotomy, only to find that the pressure of the drainage tubes induced necrosis of the contiguous ribs. He then removed pieces of four ribs, and the thickened pleura over the cavity, and evacuated a large quantity of foul-smelling pus. Hæmorrhage was free, necessitating plugging with gauze, and shock was severe. Later he found it necessary to adopt the following procedure in order to empty the cavity:—The patient, with hips raised high, resting on his shoulders, was instructed to cough repeatedly in that position, and the pus flowed out freely. He was then put in a half-sitting posture, and again repeatedly coughed, with similar result. This was done at each subsequent dressing, and in five days the pus had completely disappeared, there being now only a little serum issuing from the minute sinus left. Patient gained greatly in weight, and had lost the phthisical appearance.

TRAUMATIC RUPTURE OF THE URETHRA.

A COLLEGE professor, run over by an automobile, was carried to one of the Paris hospitals in a state of coma. Besides possible internal injuries he was found to have a fracture of the pelvis and the humerus, while the urethra was ruptured. In spite of the most active treatment the victim of the accident never recovered consciousness, and succumbed in less than twenty-four hours after the accident.

Professor Reclus, in speaking on this case, said he seized the occasion to draw the attention of the students to cases of rupture of the urethra, of which there were three varieties: Rupture of the prostatic portion, of the middle or bulbo-perineal, and of the anterior portion of the canal. The first variety, that of the patient, was rare, and could only occur in fracture of

the pubis. In general, the traumatism was so great that the victim of the accident succumbed before any treatment of the complication could be instituted.

Rupture of the urethra was easily diagnosed by the abundant hæmorrhage from the canal, the distension of the bladder felt above the pubis, and the fact that a catheter passed with the greatest care was arrested at the point named. Two methods of treatment were proposed, each one having its partisans. The first consisted in introducing a large, soft catheter up to the obstacle, and after disinfecting the perinæum, making an incision in the form of an inverted T with the cross branch just enough in front of the anus so as to avoid touching the sphincter. The parts were cut through until the end of the catheter was reached, and with the finger placed in the wound, the catheter was guided to the posterior end, and with a little patience it passed into the bladder. Sometimes, in order to find the ruptured end, it was good practice to press on the bladder so as to expel a few drops of urine. The wound was plugged with antiseptic gauze and allowed to heal by granulation.

If in spite of the most patient research, the posterior end had not been found, and consequently the continuity of the canal had not been re-established, recourse should be had to cystotomy, which was the second method and which many surgeons preferred.

The operation, as is well known, consisted in an abdominal incision going from the pubis to the neighbourhood of the umbilicus, according to the degree of *embouppoint* of the patient. The linea alba was cut through and the bladder brought to view, and opened for the space of an inch and the contents evacuated. An attempt should then be made to pass the catheter from behind forwards and crossing the rent it penetrated into the canal and finally appeared at the meatus. The bladder should be always drained by large tubes passed into the surgical wound.

These operations were very complicated and rarely successful, from the fact that fracture of the pelvis was almost equivalent to an open fracture, and consequently exposed to infection which carried off the patient from septicæmia, embolus, or diffuse suppuration.

Ruptures of the penis were still more rare; they were almost solely produced when the organ was in a state of erection, and were caused by a false and violent movement in copulation or by the stupid effort of an individual suffering from gonorrhœa, who, in order to "break the cord," forcibly bent the organ.

If the rent was incomplete, a soft catheter might succeed in passing; otherwise a button-hole should be made in the perinæum or supra-pubic cystotomy performed. Consequently, when the obstacle could not be overcome, when one or two capillary punctures of the bladder have been practised and the permeability of the canal has not been re-established, the best surgery was cystotomy as in the previous case.

Both of those varieties of rupture of the urethra—posterior and anterior rupture—were exceptional. Those met in practice were ruptures of the middle portion and were generally produced by a kick in the perinæum or a fall straddle-legged on some hard substance, and presented the usual signs—hæmorrhage from the canal, retention of urine and swelling in the perinæum. The first thing to be done was to pass a large catheter, and if it were stopped by the obstacle, no further effort should be made for the moment; the bladder should be tapped, and then the catheter tried again, and frequently success crowned the effort. Otherwise external urethrotomy should be performed.

Sometimes the rent in the urethra was only partial, a strip of mucous membrane maintained the continuity of the canal. That strip was of great service as it acted as a guide to the operator in conducting the catheter over the chasm. Where the rupture was complete the two ends of the urethra were frequently separated by a space of half an inch by reason of retraction. The point of the catheter revealed the anterior end but the other required great patience and delicate manœuvring to find.

If urethrotomy was done early, and the tissues

were not inflamed, the wound in the canal might be closed at the same time, but if the urine had had time to infiltrate the parts, large incisions should be made by the thermocautery into the inflamed tissues, penetrating right to the urethra. Later on the canal could be reconstituted and the fistulæ closed.

GERMANY.

Berlin, April 22nd, 1906.

FRAUDULENT CARLSBAD SALTS.

I HAVE been asked by the Municipal Council of Carlsbad to bring the following notice to the knowledge of the medical profession in Great Britain.

A chemist at Weissenfels obtained from a Leipzig drug merchant artificial Carlsbad Salts which proved to be a chemical compound containing admixtures of a highly poisonous nature. Several deaths have already occurred through taking this compound. This, like other imitations of genuine natural Carlsbad Sprüdel Salt, was described as "Carlsbad Salts," although it had nothing whatever to do with Carlsbad. The use of such compounds for medical purposes always involves a risk, as the purchaser is not afforded any guarantee of the harmlessness of the remedy, nor is any indication given as to its ingredients. It should be noted that genuine natural Carlsbad Sprüdel Salt is never supplied or sold loose, but only in original packages, the label, bearing the signature of the lessee of the springs, Löbel Schottländer, and this constitutes the most reliable guarantee that the purchaser will only obtain the medicament produced from the natural mineral water under the constant official supervision of the authorities. The regrettable incident at Weissenfels should serve as a caution to those who are in the habit of purchasing imitations without the advice of medical men, as it has been demonstrated by the Government and Police authorities in the present instance that the product was merely an artificial "Carlsbad Salt."

ACCIDENTS AMONG TELEPHONE GIRLS.

A brochure on this subject has lately appeared from the pen of Dr. M. Bernhardt. The writer first gives a glance over the literature of the subject, which is becoming somewhat copious, and adds thereto over sixty cases that have come under his own observation. Of these he gives a more careful account of ætiology and symptoms which leads naturally to treatment and prophylaxis.

The special injurious factor in the so-called accidents lies not infrequently in an electric current passing over the body of the operator, but the more regular course is an abnormally loud sound from the ear-piece, occasioned either by a too rapid turning of the handle for calling a person up, or one due to the weather or an atmospheric discharge.

The morbid symptoms that have been set up as the effect of a single intense sound have been described by Gradenige, Jacobson, and Passow, amongst others.

The writer's patients, whose listening ear was affected by the sharp sound, had mostly normal hearing power, and in two only out of fifty was the ear used less sharp than the other. But pain was set up in the ear and its neighbourhood, and this lasted a very long time; on some occasions the opposite ear was the site of the pain. The other symptoms of disease were paræsthesias and hyperæsthesias on the face, neck, chest, limbs, more rarely anæsthetic pareses of the upper limbs, less frequently of the lower, twitching of the muscles of the face, chorea-like movements of the arms, almost constant acceleration of the heart-beat, and, above all, psychic changes (melancholy, weeping, horrible dreams, &c.), which often resembled hypochondria with neurasthenia, whilst serious hysteria was rare.

After accidents attributable to atmospheric discharges, patients often acquired keramophobia (dread of storms), so to speak, telephonophobia.

The author believes that imitation plays a part in such nervous manifestations.

The whole group of symptoms may be classed as traumatic neuroses, and naturally prophylaxis and

treatment must correspond. When such a case comes under treatment the examination of both bodily and mental conditions must be most carefully conducted. Some protective measures should be adopted, such as isolation of the ear-piece during a storm, &c. Therapeutically, a chief theory is to calm the patient and remove fear as much as possible along with, if deemed necessary, a soothing hypnotic (veronal) pyramidon in case of pain, tonics and the employment of paradic and galvanic currents. Tepid baths he also recommends. The subject does not appear a very important one, but it would be a hardy thing to say that the slightest shock was unimportant, when the patient was an impressionable neurotic.

At the Hufeland Society Hr. Grawitz spoke on

THE FUNCTIONAL IMPORTANCE OF LEUCOCYTES.

The question was one of great practical importance. The attempt was being made to draw important conclusions as regarded proposed surgical measures from their increase or diminution. Many surgeons considered the counting of the leucocyte to be as important as taking the temperature and the pulse. From this point of view the question of the function of the leucocytes was important.

The question of their origin was not yet answered with certainty. The sharp distinctions of the various kinds of leucocytes could not justly be maintained at the present day. Their morphology had been elaborated under the ægis of Ehrlich, and his dried, coloured preparations. But the clinician, after the example of Virchow, should first examine the blood in its native state, and this should be done with every patient.

It was agreeable to chronicle a step in advance. After we have come to our limit as regarded refined microscopical technique, but using the ultra-violet rays of decomposed white light—i.e., the short, waved rays, we get a clearing up of structure twice as sharp as before. As these rays do not pass through glass, a quartz object-carrier was required. They also allowed conclusions as to the chemical composition of the preparations. Probably they were metallic substance that refracted light. (The various kinds of cells were then projected on to the screen and the different kinds described.)

We must ask what these cells signified. The nucleus of the cell must have a special function, and especially when the nucleus formed the chief mass of the cell. Where the protoplasm was further developed, the function of the nucleus became less important. In the embryo there were but few leucocytes in the blood. Lively development and activity of the nuclei first came into play at birth. This was probably connected with the function of digestion. There were from 5 to 10,000 leucocytes in the cubic millimetre. Up to recently, it was taught that leucocytes were protective organs against the entrance of foreign material. But their function must be looked upon as having a much wider range. The following might be looked upon as certainly among their properties:—(1), phenomena of movement, wandering of leucocytes; (2) phagocytism; (3) oxydising properties; (4) reducing powers; (5) absorbent properties in regard to material in solution (iron, iodine, lead, atropine, &c.); (6) assimilation; the leucocytes not only took up the bodies, but assimilated them; (7) fermentative action on break up of the leucocytes; (8) absorption of albumen, the phenomenon of digestive leucocytosis; (9) transportation of the glycogen; (10) transportation of material also outside the tissues; (11) plastic activity of leucocytes, no repair of tissues; (12) antitoxic powers as regarded clinical results. We must, for the future, go to work a little more cautiously in our judgments.

AUSTRIA.

Vienna, April 22nd, 1906.

NEPHRITIC TUBERCULOSIS.

ZUEKEREKANDL showed a case on whom he had operated for tuberculosis of the right kidney, but the point he wished most to impress on the members of the Gesellschaft was the difficulty and danger when

complicated with tuberculosis of the ureter. The semiology of the complication was not easily diagnosed, but important in the treatment. After a centre of tuberculosis is formed in the pelvis of the kidney, it is quite reasonable to expect the ureter to be affected. In all his operations for tubercle of the kidney he never once found the ureter free. The principal signs to be met with were thickening of the walls of the ureter itself as well as a fibrous fatty accumulation in the paraureteral region. This thickening of the ureter reduces the lumen of the canal often leading to obliteration and dilatation at parts in the tract. In many cases the ureteritis is in a forward state of development when the nephritic process is limited to a very small area. It is no confirmation to assume that ureteritis is not present when the bladder is found perfectly free. It will often be found that the ureter immediately above the bladder is infected when the bladder itself is perfectly free from disease. This can often be clinically diagnosed during life by attempting to get a sound into the canal. Another symptom present in all cases is the pain and tenderness along the line of the ureter, which may be found passing down behind the vagina as thick as the finger and very painful when pressed.

When the ureter is catheterised the firm resisting wall of the canal is very noticeable. The unilateral pain right or left with located cystitis would be a pathognomonic symptom in the diagnosis of tubercle in the kidney. If bacilli were present in the urine in addition to this the diagnosis would be confirmed and operation undertaken at the earliest opportunity to extirpate both ureter and kidney.

In some local cases the ureter might be left, but as a rule when thus left ulceration usually continues after the operation till death ends the suffering. In his early operations for tubercle of the kidney he seldom ever had healing of the wound by first intention, but since practising the removal of the ureter he scarcely ever has ulceration. In the literature on the subject he observes that other authors experience the same difficulty.

Kapsamer said this confirmed his own experience that he published two years ago on the subject when he removed the ureters along with the kidneys.

BACTERIA URINE.

Kornfeld next exhibited a case, æt. 25, with bacteria in the urine. He had gonorrhœa 4½ years ago, which was subsequently cured, but cloudiness of the urine still persisted, and the bladder was unable to retain more than half a litre. He was treated for some time with urotropin and helmitol—two to four grammes daily—but without any beneficial result.

In January of the present year he was received into hospital with severe gastro-intestinal disturbance, viz., loss of appetite, gaseous belching and constipation. Associated with this condition he had rigors and extreme prostration. After diagnosing bacteria urine from a presumed cysto-pyelitis, 700 cubic centimetres of residual urine was drawn from the bladder, which was afterwards well washed with a solution (1 in 5,000) of the oxide mercury. After five washings, the urine was perfectly normal in colour, which it had not been for the last four years. This condition of the urine continued six weeks. The catheter was again used, and only 200 cc. of residual urine could be taken off. The bladder was again washed and fourteen days later the residual urine of only 60 cc. could be taken off. This operation was repeated several times till no residual urine could be obtained with the catheter; urine clear and health good.

HUNGARY.

Budapest, April 22nd, 1906.

At the recent meeting of the Royal Medical Society, Professor Bókay Tános demonstrated a recovered case of

SUCCESSFUL TREATMENT OF SPORADIC CRETINISM.

First he showed projected photographs taken during the progress of a case of myxœdemetic idiocy, in which thyroid tablets were administered. The case under-

went treatment when the child was only two years of age, and after four years hardly any traces of cretinism could be found. Professor Bókay referred to the interesting cases reported in English and American periodicals as agreeing with his own extensive experience, gathered in similar cases after the systematic administration of thyroid tablets, and warmly advocated its use. In no case did he notice any pathological by-effect of the drug. He further mentioned that in exceptional cases of sporadic cretinism, when the thyroid gland was found to be in a wholly normal state, the administration of thyroid tablets would, of course, be of no avail.

A NEW PHARMACOPEIA.

Regarding the fact that since the publication of the Hungarian Pharmacopeia seventeen years have elapsed, during which period innumerable valuable drugs have been introduced into practice, and also that Hungary has been preceded by other nations in the publication of a Pharmacopeia of recent date, the Sanitary Committee of the city of Budapest has decreed that a new Pharmacopeia shall be compiled and issued as soon as possible. Substances used for preserving foods, even if they do not prevent decomposition, but only delay it, will be withdrawn from trade. The Board of Industry and Commerce requested from the Sanitary Committee the allowance of the free sale of washing soda, with the restriction that grocers must supply their customers with printed cautions as to its being poisonous. This request, however, has not been complied with, and both poisoning and adulteration will be made more difficult on the advent of the new Pharmacopeia.

THE FIGHT AGAINST CONSUMPTION

is being waged here with the greatest possible energy. Lately the post and telegraph offices with the largest traffic have been instructed to supply the premises frequented by the public with waterproof washable side-walls (cement, linoleum, asbestos), and to hang on the walls, on a visible spot, printed warnings to the public to use the spittoons. It has also been decreed that all the greater hospitals in towns shall be instructed to adopt every possible precautionary measure. In the year 1905 infectious diseases were fewer in number than in the preceding year; this particularly holds true in regard to typhoid as shown by the following table:—

YEAR	CASES.	DEATHS.
1899	909	183
1900	798	175
1901	310	75
1902	258	57
1903	217	30
1904	242	33
1905	216	29

A considerable increase has been observed in cases of diphtheria and croup. Against 830 cases in 1904 there were 1371 in 1905, the increase being 371 cases. No cases of small-pox occurred in Budapest during last year.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

SPRING GRADUATION CEREMONIAL AT EDINBURGH UNIVERSITY.

Among the recipients of the honorary degree of Doctor of Laws at the recent graduation ceremonial on the 12th inst. were Dr. Alexander Graham Bell, Professor Bergmann, Dr. David Christison, and Professor Thane. Sir Ludovic Grant, in presenting Dr. Bell for the degree alluded to his two-fold achievement in removing the barriers which disease and distance alike present to the transmission of human speech. Professor Graham Bell was the son of a citizen of Edinburgh, Alexander Melville Bell, who gained celebrity by his scientific analysis of the elements of speech. By the application of his father's system, Professor

Bell has done much to further methods of imparting hearing to the deaf and means of expression to the dumb. But it is through his invention of the telephone that Dr. Bell has gained most fame, and it is a noteworthy circumstance as showing that the telephone is of truly academic origin, that on the first occasion on which the infant instrument emitted intelligible utterance, the Professor stood at one end of the wire and a student at the other. Of Professor Bergmann, the promoter commemorated his lengthy record on the field of battle—in the Bohemian war, in the Franco-German war, at the siege of Paris, in the Russo-Turkish war, and at Plevna, and spoke of his great career as a teacher, a surgeon, and an author. Dr. David Christison is a son of the great "Sir Robert"; he was prevented by illness contracted in the Crimea from prosecuting the medical profession, and diverting his activities into other channels, has been a pioneer in scientific archaeology. Professor Thane, said the promoter, has read all that has been written on anatomical science, and remembers all that he has read. His stores of accumulated erudition have been made accessible to a far wider circle than the students who follow his lectures, for he has incorporated them in the editions of "Quain's Anatomy," which he has brought out in collaboration with other scientists. Physiology is no less beholden to him than anatomy, for he has discharged for many years difficult and delicate duties as Inspector of the Physiological and Pathological Laboratories throughout the country, with a conscientiousness and tact which have won for him the confidence of the Home Office and the medical profession.

The spring graduation is that at which arts degrees are conferred, as well as those of the faculties of science and divinity. At the conclusion of the "capping" the graduates were addressed by Professor Eggeling, the Professor of Sanscrit, who discussed recent changes in the arts curriculum.

CARNEGIE TRUST AND THE PAYMENT OF CLASS FEES.—As was mentioned in this column a week or two ago, the Carnegie trustees are no longer in the position of being able to pay the fees of all qualified students without more ado, but find it necessary to retrench, in view of the increasing demand made upon them. Certain provisional changes in the regulations will, therefore, come into force in the approaching summer session. Regulation IV. now provides that no beneficiary who has twice failed to pass one of the ordinary professional examinations will receive further class fees until he has done so. Regulation V. provides that only such students as have already passed the ordinary examination in the relative subjects or groups of subjects shall receive fees for extra classes beyond the required curriculum for the ordinary degree. Unless a satisfactory reason be given, fees will not be paid for a course of study in more than one faculty. Beneficiaries who fail to obtain certificates that they have attended the classes and duly performed the work, will be called upon to refund the corresponding fees, and fees will not be paid for classes where such certificates are not given.

POOR-LAW AND MENTAL DISORDER.

IN view of the suggestion made by the Departmental Committee on Poor-law Medical Relief, &c., that in certain poorhouses it might be desirable to treat cases of temporary mental disorder not requiring immediate removal to an asylum, the Scottish Local Government Board has issued a circular giving the conditions on which they are prepared to approve of the establishment in poorhouses of wards for the observation and treatment of temporary mental affection. These conditions may be summarised as follows: (1) Observation wards should resemble ordinary hospital wards modified to suit their special purpose; they should be separated from other wards, and no inmate who is not medically certified as suitable for treatment shall be lodged therein. (2) There should be small single rooms in proximity to the men's ward for patients whom it is desirable to isolate; where the

patients are comparatively numerous the wards should be arranged so as to admit of the inmates being grouped in accordance with their mental condition. (3) Wards should accommodate not fewer than four patients of each sex. (4) No patient shall remain in an observation ward longer than six weeks, unless under special conditions, to be reported to the Local Government Board. (5) Special registers of the patients shall be kept. (6) Where the observation wards contain sixteen beds or more, there must be at least one resident medical officer in the poorhouse. (7) The patients shall be treated on ordinary hospital lines. (8, 9, and 10) regulate the ratio of nurses to patients. (11) The consent of the Local Government Board is required before any part of a poorhouse is set apart for the observation of cases of temporary mental disorder.

From a "contributed" article in the *Scotsman* of April 13th (a day or two after the foregoing circular was issued) we extract the following:—"The Parish Council of Glasgow have recognised this"—i.e., the ready curability of certain forms of mental disorder accompanying bodily disease—"for some years, and in the old city poorhouse much good was done in the way of preventing such cases from finding their way to the asylum, and subsequently to the ranks of the unemployed. But in designing their hospitals, which are quite separate from the ordinary poorhouse, they went a step further, and at the District Hospital in Duke Street they erected a separate block specially designed for the reception and treatment of cases of mental disease, and capable of holding some 50 beds. In this matter the Parish Council were greatly helped by Dr. Carswell, the specialist in lunacy, whose services are retained by them. Dr. Carswell, indeed, may be regarded as the pioneer of this type of ward. He holds the unique, and, in a professional sense, enviable position of being at once the medical officer in charge of the mental diseases block of the district hospital, and the certifying out-door medical officer, who out of the many cases of lunacy that pass through his hands selects those that he thinks most suitable for the treatment in question. It is generally recognised that most excellent results have been obtained from the wards in Duke Street—not better, perhaps, than would have been obtained in a first-class asylum, but the stigma of lunacy is averted and the sufferer is able to return to his former calling without being exposed to the reproach that inevitably attaches to incarceration in an asylum."

Govan and Paisley have already followed the example of Glasgow by opening such wards in their poorhouses; the new Renfrewshire combination poorhouse, to be opened next month, is equipped with mental wards, and Dundee Parish Council is also moving in the matter. No doubt the Local Government Board's circular will help to ripen the opinion of parish authorities, and to bring this important matter to public notice.

LETTERS TO THE EDITOR.

CRIMINAL RESPONSIBILITY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—*Apropos* of your able and interesting article under the above headline, a work has lately been published—"Not Guilty: A Defence of the Bottom Dog," by Robert Blatchford—in which the author demonstrates a problem which has occupied the human mind for centuries, and that is the freedom or non-freedom of will, seeing that we live in much more enlightened times than our forefathers, and as the question necessarily influences legislators in framing criminal codes of law, may I offer a suggestion or two?

Sir Oliver Lodge, in the current number of a lay contemporary, the *Clarion*, altogether repudiates the notions held by the author; indeed, goes so far as to express his amazement that any sane man could hold such views. It would therefore be interesting to hear what any of your correspondents of psychological research might think on the subject.

It would appear to me that, in order to approach the problem with an unbiased mind, the individual should concentrate his attention solely on the operations or workings of some other mind, which prevents confusion of thought, and, moreover, eliminates that element of egoism and strong sentiment, or prejudice, which in nine cases out of ten overpower the reasoning faculty. With a view to this, let me suppose that any given individual is seized with the idea of committing, say, a theft and, further, that the brain of such a one, assuming it sane, perceives, as he thinks, its advantages and disadvantages, moral and material. It seems evident that these ideas—i.e., the impulse to steal, with the probable consequences, arise spontaneously in the brain, hence we have two opposing and conflicting factors at work in the mind at the same time—viz., the conceived advantages and disadvantages—and suppose the theft be committed, the conceived advantages, therefore, having conquered the disadvantages. In what logical sense can free will be said to exist in this instance, seeing, as I have stated, the idea of stealing with the advantages and disadvantages occur involuntarily?

It is, of course, obvious, notwithstanding one's ideas on the problem, that criminal law could not, under the present state of society, be abruptly dispensed with, although its severity may be minimised in the future, as, indeed, it has been in the past.

I apprehend, moreover, that no sane person would be haunted with the idea that non-freedom of will implies a licence for the committal of immoral acts, as might *prima facie* appear to some. On the contrary, a strong disposition to conform to law and order would still exist, if pre-existing, because it is the very essence of sanity or common sense to foresee the advantages of moral over immoral conduct, which reason dictates, and from which any remarkable deviation constitutes moral insanity.

I am, Sir, yours truly,

CLEMENT H. SERS.

Brighton, April 9th, 1906.

NEWSPAPERS AND QUACK ADVERTISEMENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I admire your pluck; I trust you may do some good; but I cannot see any hope of a cure for the evils you lay bare, so long as the whole newspaper press—headed, alas! by the *Times*—is against you. Not so long ago we had a truly leading journal. To have the *Times* on one's side in any fight on behalf of the public, in the exposure of any abuse hurtful to the people, gave the certainty of the battle being half won. If anyone wishes to see and appreciate how low the *Times* has in some directions fallen, he must look at page 5 of the issue of to-day (April 19th). He will there find an article headed "The Redemption of the Inebriate," prefaced by the following note:—

"These notes have been written by a member of the *Times*' Advertising Staff after thorough investigation, conducted with the assistance of an independent and registered Medical Practitioner of long experience."

This article, two columns in double-ledged leader type, is a paid puff of the "Keeley Institute." It is uncommonly well written. It is a cunningly worded sophistical argument disparaging medical science and medical men in regard to the treatment of drunkenness and lauding the efficacy of the Keeley "cure." As seems now usual with "cures" of this kind the Keeley treatment is under the special guardianship of Church dignitaries. Of these the most prominent seems to be the Rev. Canon Fleming, Chaplain in Ordinary to the King. The Keeley "cure" is, of course, merely an older variety of the several similar systems which are having their day. It is apparently precisely the same in essential characters as the newest, the "Normyl" treatment, which has lately been dealt with in your columns. It is not necessary in a medical paper to examine the claims of these cures. My sole purpose is to call attention to the deplorable fact that the *Times* is willing for money payment to give its sanction to statements such as that to which I draw

attention. This will be appreciated by anyone who cares to examine the article. One wonders what can be the feelings of the editorial staff, the champions of truth and honour, attached to a great journal, the proprietors of which have now adopted such elastic ideas as to what may be considered legitimate business.

I am, sir, yours truly,
CYNICUS.

April 19th, 1906. 1

HOME SPAS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The editorial note on the above subject in your issue of April 18th will no doubt be read with interest by the promoters of the Exhibition at the Crystal Palace, as well as by many of those affected by the prosperity of our home spas. As one who in his time has repeatedly visited most of the principal foreign springs, and is tolerably well acquainted with British resorts, I am able to recognise how much might be done to attract visitors, at any rate from among our own people, to our native cure establishments, if the managers would only strive to bring them so far as possible up to the level of their Continental rivals. At the same time, it must be recognised that our home bath establishments are in some respects hopelessly handicapped. First with regard to climate. The period during the year in which it is possible to spend much time in the open air at any season in these islands must be reckoned in days. Abroad everywhere this period is counted in weeks if not months. Then again, foreign spas are nearly all placed in the midst of, or close to fine or magnificent natural scenery; and this with the complete change of environment is naturally recognised as an advantage to most invalids. Furthermore, the amenities of all the principal Continental watering places so far surpass those of our home spas, that vast sums of money would be needed to bring them up to the same level. This especially applies to the German spas. Up to 1870, Baden Baden, Ems, Wiesbaden and Homburg were all gambling places, and for many years a large percentage of the gains from the tables had been devoted to erection of magnificent establishments surrounded by beautiful gardens. The sanitation of all these places has within late years been brought up to a high level; and indeed in this respect the Germans everywhere, if not advancing by leaps and bounds, are progressing by steady steps to the front. In France at places like Aix-les-Bains, great expenditure has been incurred in late years in improvements. It must be also admitted that foreign hotels and restaurants are ahead of those at home in many essential respects, among which the variety and excellence of the cooking, and the provision of suitable dietary for the different classes of invalids, stand out prominently. In the way of brightness derived from amusements, the foreigners are also able to in many ways beat us, and especially with regard to music. A really high-class orchestra is too costly in these islands; it can, as a rule, be easily supplied abroad. The taste for superior music has widely extended within recent years, with the growth of dislike of anything below a certain level. Inquiry will prove that a notable proportion of people are driven abroad by the consideration that they will there enjoy good music, or at least be saved the torment which the hyper-sensitive ear of an invalid often experiences, when compelled constantly to listen to the ill-played dreary selections of popular tunes which too often form the repertory of our native bands.

I am, Sir, yours truly,

VIATOR.

April 21st, 1906.

THE MEDICAL ELEMENT IN THE RECENT "RAGGING" CASE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Now that sentence has been pronounced in the recent case of "ragging" in the Scots Guards, and the incident is open to comment, I should like to know the views of the profession upon Surgeon-Major Whiston's conduct in the affair from a medico-ethical

point of view. He saw Mr. Kennedy as a patient, and as one who, from his own evidence, was in a febrile condition, and suffering from a sore and tender mouth. Was he at liberty to report to the Colonel as he did? Evidently it was not his duty, or the Army Council would not have expressed their displeasure with his conduct. The results of his conduct are far reaching and painful, and will not make his life a bed of roses as he looks back upon "the might have been," had he been gifted with a little more of the milk of human kindness, and not dealt so harshly with a young fellow who may have been at fault and to blame, but, who might have been reformed in other ways with a little more tact and kindness, or have been got rid of quite as effectually by other and less reprehensible ways.

I am Sir, yours truly,

"ENQUIRER."

Sheffield, April 24th.

OBITUARY.

PROFESSOR GEORGE BUCHANAN, OF GLASGOW

DR. GEORGE BUCHANAN, formerly Professor of Clinical Surgery, in Glasgow University, died at Stirling on April 19th, in his eightieth year. He was over seventy years of age, when he sought retirement from the active duties of a surgeon. He graduated in the year 1849, as L.R.C.S. Edin., and M.D. St. Andrews, receiving the honorary degree of L.L.D., for his distinguished services to surgery. He was a great practical surgeon and his surgical work rested on a profound knowledge of anatomy, which he had obtained as teacher of anatomy in Anderson's College, in his younger days. He edited the tenth edition of Wilson's "Anatomist's Vade Mecum." His father, Dr. Moses Buchanan, was also a Professor of Anatomy in Anderson's College, being succeeded by his distinguished son. Dr. George Buchanan was, in his younger days, surgeon to the Royal Infirmary, where the great Lister was solving the problem of how to stop suppuration in wounds by the use of antiseptics. Dr. Buchanan transferred his services, later, to the Western Infirmary, on the opening of the latter institution, and was appointed Professor of Clinical Surgery. His great rival through life—and it was a friendly emulation—was the late Sir George H. B. Macleod. Sir George was tall and handsome, was kindly in presence, and possessed charming manners. The "wee" George, as he was called by the students, was a plain man, rather small of stature, with great roundness of figure, and blunt, quick, and incisive in speech and manner. He did everything quickly, active in his habits, swift in the execution of a surgical operation, and undaunted when confronted with difficulties. He was a bold and fearless operator, opening into the brain and the abdomen, when most surgeons were deterred by the bogey of the "peritoneum," and the danger of meningitis. As a teacher of surgery and of clinical surgery, he was pre-eminent, portraying diseases in bold outlines, and rapidly explaining the main facts without labouring at minutiae. By his death thousands of people, all over the country, who had found in him a friend in need and in the hour of danger, will be saddened; while to the vast array of students who passed through his hands, and learned from his lips the pithy words of wisdom and caught something of his manly spirit, his death will come as a shock at the loss of the great surgeon whose memory will ever be held dear to those who knew him and loved him.

J. T. M.

HENRY ALEXANDER GOGARTY, M.D., L.R.C.S.I.

THE death occurred at Canterbury on the 18th inst., of Dr. Henry Alexander Gogarty, from heart trouble. He obtained his medical education at Trinity College, Dublin, and Paris, qualifying L.R.C.S.I. in 1853. M.D. in 1878, and M.B. 1867. Formerly a surgeon-major in the Rifle Brigade, he spent the latter

part of his life in Canterbury, where he became a prominent and respected citizen. For nearly 30 years he held the position of honorary physician at the Kent and Canterbury Hospital; and upon his retirement in April, 1904, owing to failing health, was elected honorary consulting physician, and thanked for the services which he had rendered to the hospital for more than a quarter of a century. He was also for many years lecturer on practical medicine at St. Augustine's Missionary Training College, Canterbury.

THE CHEMISTS' EXHIBITION.

THIS annual function which opened on Monday last, and is continued during the present week at the Royal Horticultural Hall, Westminster, is organised by the *British and Colonial Druggist* journal, and is attended by chemists from all parts of the United Kingdom, the Colonies, America and the Continent of Europe. Special excursions are run by the railways from every considerable town in Great Britain. The exhibitors include the most prominent wholesale firms supplying chemists and druggists, and the exhibition is so popular that every inch of space is let within a few days of the issue of the plan. There are over one hundred stands, some of a very costly description, and whilst it is an important mart, it constitutes the largest social reunion of the drug trade. Various meetings connected with the chemists' trade being held during the week.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.

THE quarterly examinations of the above Board, held in Edinburgh, were concluded on the 11th inst., with the following results:—

First Examination, Four Years' Course.—Messrs. Richard Burrows Sephton, and Tirunarur Arunachala Ramaswami Aiyar, passed the examination.

First Examination, Five Years' Course.—Of 32 candidates entered, the following 19 passed the examination: Harry Ellison, Richard Dorset, Walter Crosse, Herbert Christian Bankole-Bright, Richard Parry, Baldey Singh, John William Hitchcock (with distinction), Harold Gordon Chouler, Ralph Christopher Fuller, Hugh Clement de Souza, Ernest Justin Vaillant, Dakshina Ranjan Das Gupta, George Nicol Groves, Henry Ernest King Fretz, Gordon Beveridge, Donald Morrison, Charles Gordon Timms, Arthur Lidgely Salmon, and Munchersha Byramji Irani; and four passed in Physics, three in Biology, and one in Chemistry.

Second Examination, Four Years' Course.—Mr. Aiknath Visajee Bam passed the examination.

Second Examination, Five Years' Course.—Of 19 candidates entered the following six passed the examination: Louis Nathaniel Robertson, Samuel Middleton Ware, Daniel Murphy, Ishmael Charles Pratt (with distinction), Frederick Robert Watson, Edward Peake Maitland, Thomas James George, and John Patrick Synnott; and three passed in Anatomy and one in Physiology.

Third Examination, Five Years' Course.—Of 36 candidates entered the following 26 passed the examination: James Haig Johnston (with distinction), Andrew Johnstone Brown; George Hector Urquhart, Owen Thomas Jones, William Taylor, Percival Thomas Rutherford (with distinction), Oliver Carlyle (with distinction), Joseph Henry Bennett, William Roberts Ellis, George Whitfield Knipe, Charles Liston Stewart, John Albert Henry Muller, John Henry Morris-Jones (with distinction), Jane Hall Filshill, William Francis Gordon Scott, Arthur Patrick O'Connell, Khorshed Sorabji Kanga (with distinction), Michael Joseph Hayes, Cecil Berry, Dora Robbins, Secosene Piarroux, Cowan Jones, Peter Stewart, Munchersha Byramji Irani, Jitendre Nath Rai, and Vinayak Shantaram Sanzgiri; and one passed in *Materia Medica*.

DR. ROBERT DENMAN is returning this week to resume his work as Medical Officer of Health in the Seychelles Islands.

MEDICAL NEWS IN BRIEF.

Suicide of a Medical Man on a Golf Link.

AT New Southgate on Saturday, Coroner Thomas held an inquiry into the death of Mr. Frederick Stephen Alford, 55, L.R.C.P.Lond., M.R.C.S.Eng., surgeon to the Haverstock Hill Dispensary, whose body was found on the links of the Hampstead Golf Club. Deceased, a well-known North London medical man, had been in practice in Hampstead for over twenty-five years. A nephew said he had no trouble, and had never threatened to take his life. On the previous Sunday morning deceased took a number of prescriptions to a chemist, from whom he purchased an ounce bottle of hydrocyanic acid, saying it was for an "animal case." Then he went to the golf links, and after chatting for some time with the steward, walked to a small wood close to the links. The steward found his dead body there on Wednesday, and by his side was a medicine glass. The bottle which had contained the poison was found in his waistcoat pocket. The jury returned a verdict of "Suicide whilst of unsound mind."

A Fortunate Next of Kin.

AFTER four years litigation in the Australian Law Courts, intelligence has been received by a shoemaker in the South of England that a fortune of £100,000 has been decided in his favour, subject to certain allowances to other relatives, as next of kin by marriage under the will of the late Mr. Osmand. It appears that in the early years of the last century, Dr. James Osmand, a naval surgeon, who had been engaged in the battles of Trafalgar and Algiers, retired from the service, and went to live at Plympton, a few miles outside Plymouth, where he spent the rest of a long life in private practice. His son, William H. Seville Osmand, emigrated to Australia in the days when the gold fever was at its height. He was successful in his mining operations, and with the capital acquired thereby he embarked in sheep farming on a large scale, and ultimately became the owner of three large estates, one at Sydney, another at Melbourne, and a third in Western Australia. Entering public life, he became a member of the Legislature of Victoria. He married an Australian lady, but his wife predeceased him, and there was no issue of the marriage. His death took place in Victoria on March 11th, 1901, and in accordance with his last request, his body was brought to England, and buried in the same burial ground as that containing the bodies of his parents.

King Edward the Seventh's Coronation National Fund for Nurses in Ireland.

A QUARTERLY meeting of the above society was held at 86, Lower Leeson Street, on the afternoon of Wednesday, the 11th inst. The minutes of the quarterly meeting held January 10th were read and confirmed. The Hon. Treasurer's accounts were read and passed. Applications for memberships from fourteen nurses were considered and accepted. An application for assistance having been made by one of the Nurse Members, the Council, after considering the case, granted her the sum of £12. A letter from Her Excellency the Countess of Aberdeen, in which she graciously signified her willingness to accede to the request of the Council to become Patroness of the Society was read, and a vote of thanks to Her Excellency was passed unanimously for so doing. The annual general meeting was fixed for Monday, May 14th next at 4 p.m.

The Election at Dromore West Union Dispensary. Alleged Bribery.

IN November last, the Guardians of this Union elected Dr. Clarke to the vacant post of medical officer, selecting him from two candidates, of whom the other was Dr. Denis Maguire. Dr. Maguire has now applied to the King's Bench for an order of *quo warranto* with a view to establishing his objection to the election. Dr. Maguire, who appeared for himself,

read an affidavit in which he stated that during the election he and Dr. Clarke were the candidates, and that the applicant received one vote and Dr. Clarke 28 votes. The affidavit stated that a short time before this election Dr. Clarke had been in possession of an evicted farm known as Sweeney's boycotted farm, that all branches of the United Irish League in the Dromore West Union were put in motion, and a conference was called to take steps in reference to the election in question, and eventually the election resulted as above. The applicant alleged that Dr. Clarke was elected by bribery, and the applicant also alleged that Dr. Clarke was at the time of election disqualified, and that as a result the applicant was the only real candidate for the office, and should have been elected. In answer to Judge Andrews, Dr. Maguire said he wanted the order addressed to Dr. Clarke. This the Court refused to do, and said that Dr. Maguire must serve notice of the application on Dr. Clarke and any other party to the election, and then the matter could at once be fully heard. Dr. Maguire then intimated his intention of going to the Court of Appeal.

Lisbon Medical Congress. Opening Speech by King Carlos.

THE fifteenth International Medical Congress was opened by the King on April 19th. His Majesty alluded to the religion of duty, solidarity and fraternity, and remarked that the nations were fighting in the laboratories evils by which more people were killed than by wars. Himself an ardent student of natural sciences, the King could admire the work of the congress, while his beloved Queen by her participation in the struggle against tuberculosis had proved that her heart was with the congress. He was proud to preside over a gathering the presence of which was an honour to Portugal. After the President and Secretary had spoken, the official delegates of twenty-four nations in turn addressed the congress. Then followed Professor Posner, of Berlin, the President of the International Association of the Medical Press, which has been holding meetings during the last two days at Lisbon, and will assemble in London next year. An address by Senhor Luciano de Castro, the Prime Minister, concluded the proceedings.

The Port of London.

DR. HERBERT WILLIAMS, the medical officer of the Port of London, in his annual report to the City Corporation, makes a lengthy reference to the working of the Aliens Act, and to the filthy condition under which many hundreds of Russian immigrants reached these shores. The facts were reported to the Board of Trade and as the vessels carrying the immigrants were under the Russian flag, representations were made, through the Russian Consul, to St. Petersburg. Cases of infectious disease to the number of 211 were treated last year at the Port Sanitary Hospital at Denton, near Gravesend. Dr. Williams expresses a fear that cholera may re-appear on the Continent this year, especially if the weather is very warm, in which case, he says, it will be necessary to observe strictly every possible precaution to ensure that persons coming from infected parts are kept under observation after landing in this country. It may even be necessary to place greater restrictions on the landing of alien immigrants. During the period under review 385,162 rats were destroyed in dock warehouses, and on board vessels. Packages of unsound food numbering 32,673 were seized and destroyed, as also were 181,838 loose articles.

Royal College of Physicians of Ireland.

AT the last meeting of the College, Dr. E. J. M. Watson, M.D. Dublin, and Dr. T. G. Moorhead, M.D. Dublin, were elected to the Fellowship of the College. Mr. J. Spencer Sheil, L.R.C.P. and S.I., having passed the necessary examinations has been admitted to the Membership of the College.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

Utilisation of Different Varieties of Sugar in Diabetes.—Petitti (*Berlin Klin. Woch.*, 1906, No. 6) has experimented with different sugars in diabetic patients, giving them by the mouth and also in the form of enemata, and has made observations on the amounts excreted in the urine and fæces. He found that sugar given per rectum was absorbed just as well, or even better, than that given by the mouth. No matter what sugar was given, there always resulted an increased output of dextro-rotatory sugar. Lactose appeared to be best utilised, and grape sugar worst. In severe cases of diabetes, the existing acidosis, and also the sugar output, was quite unaffected by the sugar intake. Sugar clysters, he thinks, may find a place in the diabetic diet. The sugar introduced in this manner passes for the most part *via* the superior hæmorrhoidal vein to the portal system and liver, while only a small part gets directly into the inferior vena cava through the inferior hæmorrhoidal vein. The transference of all carbohydrates that reach the liver, into glycogen, and the subsequent change of glycogen into dextrose, explains the excretion of dextrose even after the administration of lævulose. M.

Calcium Chloride in the Treatment of Headaches.—Dr. George Ross (*Lancet*, Jan. 20th, 1906) describes a peculiar form of headache most often found in women, to which he applies the term "lymphatic type of headache." Its characteristics are as follow:—(1) It is most severe on waking, and gradually diminishes during the next few hours; (2) it usually manifests itself as a dull, heavy ache, and it is exceedingly chronic; (3) it is associated with a deficient coagulability of the blood; (4) complications, such as urticaria, chilblains, and localised œdema, usually co-exist; (5) it can generally be relieved by the administration of large doses of calcium chloride. This treatment was suggested in one case by the finding of deficient coagulability of the blood and of urticaria, and proved so successful as to lead Dr. Ross to regard the headache as caused by a "serous hæmorrhage" into the brain. This opinion has been confirmed by the observation of other cases, in all of which he found improvement to take place, when the coagulation time of the blood had been shortened by the aid of calcium chloride in large doses. M.

Bronzed Diabetes.—Hess and Zurhelle (*Zeitschrift Klin. Med.*, 1905, Bd. 57) report two cases of this rare condition. As in most previously recorded cases both patients were young men, and had been accustomed to drink beer freely. They died ultimately from diabetic coma, after a long duration of the illness. The liver cirrhosis was clinically and anatomically a hypertrophic form of Lænec's cirrhosis. The hæmochromatosis consisted in the laying down of iron containing and iron free pigment in the skin and internal organs. The liver contained in one case 7.1 per cent. of iron after drying, *i.e.*, 38.7 grammes. In the other case hæmoglobinuria had existed during life, and also marked lipæmia. The authors believe that the various pigments are all the result of a general hæmolysis. They also think that the liver cirrhosis is not secondary to the deposit of pigment, but must be regarded as an independent process. Probably both pigmentation and cirrhosis result from the metabolic disturbances caused by alcohol; the diabetes is a secondary disease. M.

Renal Opothrapy.—Choupin writes (*Revue de Med.*, 1905, Nos. 1 and 2) on opotherapy for renal disease, and points out that three methods of it exist, namely—(1) treatment with nephrin, or kidney extract; (2) treatment with blood serum obtained from the renal vein; (3) treatment with pulverised kidney sub-

stance. He himself employs Renaul's method, which consists of macerating fresh, raw kidney substance in saline solution. The solution is strained through linen, is then suitably flavoured, and can be drunk cold or lukewarm. Two pork kidneys daily furnish the requisite quantity of kidney substance, provided they have been obtained from young, full-grown animals. Choupin has treated many cases of Bright's disease in this way, and regards the method as an important therapeutic agent. The fluid is not disagreeable, and is easy to take. It is a powerful diuretic, and acts in this way by direct stimulation of the renal cells, instead of by increasing the blood pressure, while its other beneficial properties are ascribed to an internal secretion of the kidney. M.

Gastro Myxorrhœa.—Kuttner, writing in the *Ewald Festnummer of the Berlin Klin. Wochenschr.*, describes under the above name a hypersecretion of the gastric mucus occurring in the empty stomach. Whilst we normally only find about 1 cc. of mucus in the empty stomach, one may in this pathological condition find as much as 25 cc. These cases are by no means rare, but one should not make the diagnosis of mucous hypersecretion, unless a large quantity is constantly present, or returns after a short interval. The reaction of the mucus is neutral, alkaline or slightly acid. Hydrochloric acid is usually absent, unless *gastrosuccorrhœa* is also present. Two forms of *gastro-myxorrhœa* are distinguished, namely, an intermittent and a chronic form. The first begins with headache, anorexia and nausea, setting in in the morning before breakfast. These cases last about a day, and resemble the gastric crises of *tabes dorsalis*, and the best treatment for them is a hypodermic injection of morphia. The chronic form may have few or no subjective symptoms. Usually there is chronic catarrh and various nervous manifestations. Lavage, alkaline waters and regulation of the diet so as to avoid vegetables and alcoholic drinks, constitutes the best line of treatment. M.

Treatment of Warts.—Hall (*Brit. Journ. Dermat.*, March, 1906) publishes a note on the treatment of simple warts by internal remedies. He had previously written on the subject and suggested the use of magnesium sulphate, but is now rather inclined, with Dr. Chalmers Watson, to attribute the successful result to the free purgation, and not to the particular drug. A child, æt. 14, the backs of whose hands had literally been covered with warts since childhood, was first treated with *mist. alba*, but no change was produced in the warts, and the bowels remained constive. Subsequently she was given *conf. sulphuris* and *conf. sennæ*, but with no better result. The treatment was now changed to *pil. aloin* (gr. $\frac{1}{2}$), *c. nux vomica* (gr. $\frac{1}{2}$), and almost at once distinct improvement was noticed. The bowels became regular and the warts diminished in size so that in about ten weeks only quite a few shrunken warts were left on the fingers. K.

The Results of Anti-enteric Inoculation.—Ward (*Journ. R. Army Med. Corps*, April, 1906) records the results obtained from this inoculation in the case of the 7th Hussars. The regiment embarked for South Africa on November 30th, 1901, with a strength of 26 officers and 524 N.C.O.'s and men. Out of these, 20 officers and 213 N.C.O.'s and men were inoculated twice, and 75 N.C.O.'s and men were inoculated once; the others were not inoculated. Among the uninoculated officers three were over 30, and had already been on active service, while one had already had enteric fever. The first dose was 0.5 cc. of vaccine fluid supplied by Professor Wright; the second dose was 1 cc. given after an interval of eight days. Very few of those inoculated suffered any inconvenience and

in no case was there any severe reaction. It was noticed that the general reaction was most marked in those who had previously had enteric and least in those who were heavy smokers. During the six months which the report covers the regiment was engaged on active service under every condition of trekking and in towns. During the six months there were in all 29 cases of enteric fever; six in those inoculated twice; three in those inoculated once, and 20 in those uninoculated. No officer contracted the disease. There were three deaths from enteric fever, all in those uninoculated. During the last five months covered by this report the 2nd Dragoon Guards, an uninoculated regiment which had landed a few months before the 7th Hussars with a strength of 357 N.C.O.'s and men, were with this latter regiment and under exactly similar conditions; they are, however, known to have lost one officer and over 20 men from enteric fever during this period. April 13th, 1902, a draft of forty-eight men arrived for the 7th Hussars; they were uninoculated, and on June 20th there had been among them four cases of enteric fever with one death. Between June, 1902, and December, 1905, only one case of enteric fever occurred among those inoculated twice, one among those inoculated once, and 16 among the uninoculated. K.

Rhythmic Displacement of the Heart as a Sign of Pleural Effusion.—Green (*Amer. Journ. M. Science* March, 1906) discusses the value of a rhythmic lateral displacement of the heart synchronous with respiration as a sign of unilateral liquid exudate in the pleural cavity. He has observed many cases of effusion from different causes, and has estimated the movement of the heart by means of auscultatory percussion, combined with the fluoroscope. In all cases of unilateral effusion he was able to demonstrate the rhythmic lateral displacement of the heart though this phenomenon was not observed in any other conditions of the pleura examined. Green has been unable to confirm the correctness of the observations leading to the statement that in certain cases of this sort the diaphragm is absolutely paralysed and in some instances forced downward so as actually to bulge into the peritoneal cavity. Green offers the following conclusions as the result of his investigations: (1) A rhythmic lateral movement of the heart occurs in unilateral liquid pleural effusions. (2) Such movement is most marked in medium-sized effusions. (3) The heart approaches the affected side in inspiration and moves outward in expiration. (4) The extent of the movement is variable but often amounts to two inches. (5) It may be measured by fluoroscopic examination, auscultatory percussion, or, in the case of right-sided effusions, by simple deep percussion of the free cardiac border, or in some instance by mere inspection of the apex beat. (6) Deep breathing and especially forced expiration are essential to the success of the manoeuvre, and to obtain this morphine must sometimes be administered. (7) Marked rhythmic lateral movement has not been found in pneumonia, tuberculous infiltration of the lung, malignant disease of the pleura or lung, or in subdiaphragmatic abscess. This sign may then be looked on as of considerable diagnostic value in the differential diagnosis of intrathoracic disease. K.

New Method of Testing Functions of Digestive Apparatus.—Einhorn (*Med. Record*, New York, February 10th, 1906) attaches solid food stuffs to glass or porcelain beads, by drawing them through the opening in the bead and tying them on with silk thread. Examination of the beads found in the fæces will reveal the indigestible substances, while those which are digestible will have disappeared during their course through the gastro-intestinal tract. In order to test the work of the stomach alone, a thread is attached to the beads, which are placed in a gelatine capsule. At the end of from four to six hours the beads are withdrawn. By these two methods both the digestion in the stomach and bowel may be judged. Einhorn sums up the results of his experiments as follows: "In the case of individuals catgut and fish bones

are digested in the stomach, whereas boiled or raw meat (beef), raw chicken skin, and raw as well as boiled potatoes do not disappear altogether in this organ. The muscles show a swelling and loosening of the fibres. Raw muscle fibre and chicken skin disappear in the intestines; tendons remain undigested. Raw potatoes show a varying condition, sometimes disappearing entirely, sometimes going through unchanged. Boiled potato usually seems to be digested in the bowel, but the skin of the potato, raw or boiled remains unchanged. Fats with a very high melting-point, such as lard are not absorbed in the intestine; suet and mutton fat are digested in the bowel. Fish bone is not changed in the intestinal tract. If the intestinal functions are normal albumin (raw meat) and starch (potato), boiled two minutes, and mutton fat will disappear during their passage through the digestive tract. Disturbance of these functions may be recognised by the reappearance of food substances attached to the beads. Raw thymus has been used to test the pancreatic function. When the intestinal and pancreatic functions are intact, the thymus will disappear. D.

X-ray Diagnosis of Thoracic Aneurysms.—Bætjer (*Johns Hopkins Hosp. Bull.*, January, 1906) reports four years' experience at the Johns Hopkins Hospital with X-rays in the diagnosis of thoracic aneurysm. This diagnosis was made 104 times. In 70 to 75 per cent. of the cases the diagnosis had already been made by other methods. The X-rays practically always confirmed the medical findings. In 20 to 25 per cent. the diagnosis was doubtful, but, in many instances, the subsequent course of the disease proved the X-ray diagnosis to be correct. In 5 per cent. of the cases the aneurysm was found by accident, there being no physical signs. Eighteen per cent. of the cases came to autopsy, and the X-ray findings were always confirmed. D.

Syphilis or Mercury.—Wolter (*St. Louis Courier of Medicine*, February, 1906) holds that the theory that paralytic dementia and tabes, in 90 per cent. of all cases, are meta-syphilitic conditions, is not so sound as the theory that the diseases are usually a meta-mercurial condition. He does not deny that paretics and tabetics are syphilitic, but believes that it is equally true that they have been mercurialised. As a result of considerable study he inclines to the belief that mercury and not syphilis is responsible in the etiology of paralytic dementia and tabes. He says there are important reasons for the belief that syphilis plays a minor role in the etiology of sclerosis of the brain and cord. Although the negro is very prone to contract syphilis, paresis and posterior spinal sclerosis are seen rarely in the coloured race. The average negro most frequently receives no treatment for lues, and the most severe secondary and tertiary lesions are found in the coloured man. Having become a syphilitic, he allows the disease to run a typical course without interference. If he does take mercury, it is with no system; it is taken irregularly and for no prolonged period of time. Yet in spite of all this, he does not become the victim of paresis and tabes. On the other hand, the man of brains, the professional man, the highly educated man, falls a ready victim to paresis. The requisites of thorough antisiphilitic treatment are brains and money, and since these are the essentials in obtaining the treatment, Wolter believes that there is the reason why paretics and tabetics are usually individuals of prominence. D.

NOTE.—A summary will appear each week in the following sequence:—

- (1) "Recent Medical Literature."
- (2) "Recent Surgical Literature."
- (3) "Recent Gynecological and Obstetrical Literature."
- (4) "The Recent Literature of Physiology and Pathology."

REPRINTS—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CAUTION TO OUR READERS.

We understand that an individual, representing himself as Dr. Robinson, at other times as Dr. Williams, has been calling on medical men professing, by way of introduction, a personal friendship with some well-known New York physicians, finally winding up a hasty interview with a regret that he has suddenly found himself to have been robbed of his purse, and would Dr. — kindly loan him 5s. to get back to his hotel, when the money will be immediately returned. This man we have ascertained is a Russian Jew, speaks English fluently, and is partial to umbrellas and such like portable articles when not personally shown the front door.

T. B. A.—We hope to deal with the subject in our next.

ONE OF YOUR READERS—Your communication reached us while the journal was "at press."

DR. WINTER—We understand that a meeting will be held the last week in May, when previous references will be reported on and decisions arrived at.

B. (Liverpool)—According to the official returns of the Registrar-General, Glasgow has the next largest population in the United Kingdom to London. Liverpool comes next, with a population of about 100,000 fewer than Glasgow.

DR. W. A. S. (Galway)—In answer to your inquiry, the Easter Session of the Medical Graduates' College and Polyclinic (Chenies Street, Gower Street, London) begins on April 30th.

THE "DAILY MAIL" AND ADVERTISEMENTS.

Our attention has been called to certain observations relating to Rile Beans contained in a leading article, entitled "The Daily Mail and Advertisements," which appeared in our issue of March 14th. The Manager of the Rile Beans Manufacturing Company assures us that Mr. Thomas Oxhill's testimonial, to which we referred, is genuine, and he further assures us that the analysis of the composition of Rile Beans quoted by us from Dr. R. H. Hutchinson's work in that article is incorrect. This being so, in common fairness we must admit that our deductions as to the medicinal value of Rile Beans are inaccurate, so far as founded on that analysis. Further, we are informed that the Judge in the case referred to in no way dealt in his judgment with the composition of Rile Beans, his verdict being based on certain advertisements issued by the Rile Beans Company. We readily give this explanation, and express regret if our criticism was based upon incorrect premises.

G. WYATT (Lancs.)—The existence of the "bonesetter" forms a scathing comment on the methods of our rulers, who are content to frame more or less drastic laws for the education and control of qualified medical men, but who at the same time allow all kinds of unqualified persons, to hatter upon the community. It is likely that anyone who had suffered injury at the hands of a "bonesetter" would be able to recover heavy damages in a court of law. Such persons, however, are loth to come forward.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, APRIL 26th.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8 p.m. Annual Meeting. Election of Officers for the ensuing year. 8.30 p.m. Adjourned Discussion on Syphilis (resumed by the President, Dr. F. J. Smith). The following, amongst others, are expected to take part:—Dr. T. Shennan, Demonstration of *Spirochæta Pallida*; Dr. G. F. Still, The Disease as met with in Children; Dr. J. H. Sequeira and Dr. M. Dockrell, Syphilitic Affections of the Skin; Dr. W. J. McC. Eccles, General Treatment.

THURSDAY, APRIL 26th.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Paper:—Dr. G. W. Hill: Artificial Aids to Hearing.—Mr. W. H. C. Greene: Simple Tumours and their Relation to Malignant Disease.

FRIDAY, APRIL 27th.

BRITISH ELBROTHERAPEUTIC SOCIETY (11 Chandos Street, Cavendish Square, W.).—8 p.m. Council. 8.30 p.m. Dr. D. Arthur, will show the West London Hospital X-ray Table. Paper:—Dr. W. F. Homerville (Glasgow): The Influence of High Frequency Currents on the Surface Temperature of the Human Body (illustrated with lantern slides).

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m. (Clinical Evening for the Exhibition of Clinical Cases followed by Discussion. Patients in attendance from 8 p.m. to 9 p.m.

Vacancies.

Seamen's Hospital, Cronstadt.—Resident Medical Officer. Salary £180 per annum, free lodgings, lights, fuel, and attendance. Applica-

tions to Chairman of Hospital Committee, British Consulate, St Petersburg.

The Royal Albert Asylum, Lancaster.—Junior Assistant Medical Officer. Salary £125 per annum, with board, apartments, and washing. Applications to Archibald R. Douglas, Medical Superintendent.

Littlemore Pauper Lunatic Asylum, Oxford.—Second Assistant Medical Officer. Salary £120 per annum, with furnished rooms in the Asylum and board. Applications to Thomas M. Davenport, Clerk of the Visiting Committee, County Hall, Oxford.

Macclesfield General Infirmary.—Senior House Surgeon. Salary £100 per annum, with board and residence. Applications to the Chairman of the House Committee.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary £150 per annum, with apartments. Applications to the Hon. Secretary, Mr. G. A. Lightfoot, 23 Castle Street, Carlisle.

University of Birmingham.—Assistant Lecturer on Pathology and Bacteriology. Salary £250 per annum. Applications to Geo. H. Morley, Secretary.

West Herts Infirmary, Hemel Hempstead.—House Surgeon and Assistant Secretary.—Salary £110 per annum, with furnished rooms, board, fire, lights, washing, and attendance. Applications to the Hon. Secretary.

The Barbados General Hospital.—Junior Resident Surgeon. Salary £200 per annum, with quarters. Applications to Mr. N. E. Sargeant, School Registrar, St. Bartholomew's Hospital, London.

Warrington Infirmary and Dispensary.—Junior House Surgeon.—Salary £100 per annum, with furnished residence and board. Applications to J. H. J. Hampton, Secretary.

Cornwall County Asylum, Bodmin. Third Assistant Medical Officer. Salary £135 per annum, with board, furnished apartments, washing, &c. Applications to Medical Superintendent.

Montrose Royal Asylum, Sunnyside, Montrose.—Senior Assistant Medical Officer. Salary £200 per annum, with board, lodging, &c. Applications to Dr. Havelock, Medical Superintendent.

Essex and Colchester General Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and residence in the Hospital. Applications to Alfred O. Buck, Secretary, the Hospital Colchester.

Appointments.

LENNANE, GERALD QUIN, F.R.C.S. Eng., L.E.C.P., Medical Officer of Health of the Borough of Battersea.

MACGILLVEAY, W. J. HOOKER, L.R.C.P., L.E.C.S., L.M.Edin., L.F.P.S., L.M.Glasg., Medical Officer to the Fallowfield and Withington District of the Royal Rusholme Provident Dispensary, Manchester.

Births.

CHANNING PEARCE.—On April 19th, at 88 St. James' Road, West Croydon, the wife of A. Channing Pearce, M.D., of a daughter.

CURTIS.—On April 20th, at Lynde's, Redhill, the wife of Frederick Curtis, F.R.C.S., &c., Eng., of a daughter.

HIGSON.—On April 12th, at "Oakmers," Honor Oak Park, London, the wife of J. Russell Higson, M.B., C.M.Edin., D.P.H. Camb., of a daughter.

Marriages.

DONNAN—MAGEE.—On April 19th, at St. Matthias' Church, Dublin, Wm. Dunlop Donnan, M.D., eldest son of Wm. Donnan, Holywood, Co. Down, to Alice Caroline Isabella, only daughter of D. Magee, Esq., D.I., Taghmao, Co. Wexford.

FOX—FOX.—On April 19th, at All Saints' Church, Holbeton, Edward Hamilton Bruce Fox, M.R.C.S., L.R.C.P., of Woolston Lodge, Southampton, son of Francis Edward Fox, J.P., of Upland, Tamerton Foliot, and Maude Geradine, second daughter of Charles Alfred Fox, of Battisborough House, Holbeton.

HEARDER—STEWART.—On April 18th, at St. Issell's, Saundersonfoot, Frederic Pollington Hearder, M.D., of Whitley, Yorkshires, to Catherine Frances, third daughter of Alexander Stewart, of Saundersonfoot, Wales.

HODSON—HY E.—On April 21st, at the Parish Church, Burton, Thos. George Smith Hodson, M.D., of 10 Terrace Road, to Margaret Mary Mallalieu Hyde, only child of the late Samuel H. de, M.D., of Lisamore House, Buxton.

PEATING—BARROW.—On April 19th, at All Saints' Church, Cershalton, Albert Victor, M.B., B.O., B.A., youngest son of the late Frederic Peating, J.P., and Mrs. Peating, of Levington Hall, Wisbeck, to Muriel Palliser, only daughter of Samuel Barrow, junr., of The Grove, Cershalton, Surrey.

RHODES—SANDERSON.—On April 19th, at Ardingly, T. Basil Rhodes, M.B., B.S., of Bagley Sanatorium, Timperley, Cheshire, second son of T. E. Rhodes, Esq., formerly of Brewod, to Mary Sanderson daughter of the late Christopher Sanderson, Esq., of York.

Deaths.

CHIPPERFIELD.—On March 13th, at Ladysmith, Natal (thrown from his horse), William Richard Hopkins Chipperfield, M.L.C.E., second son of the late Surgeon-Major W. N. Chipperfield, I.M.S., and only brother of Pearce Chipperfield, M.R.C.S., L.R.C.P., of Hampton Court.

WALTER.—On April 17th, at Peterborough, Jane Emmonson Walter, eldest daughter of the late Odiarne Coates Walter, M.R.C.S., of Broadstairs, aged 68.

SPACKMAN.—On April 21st, in London, Coniston Spackman, M.R.C.S., L.R.C.P., of Maidenhead, eldest son of the late Dr. Frederick Charles Spackman, of Faringdon, Berks, aged 44.

NOTES AND COMMENTS.

The Insane Patient.

THE risks of the medical profession are multifarious and universal. A remarkable case recently heard at the Aston Police Court illustrated in typical fashion the danger of the patient afflicted with delusions of personal injury. Some while ago a mysterious and unwarrantable assault was committed by a woman upon Dr. Fairley, of Birmingham. The unfortunate victim was thrashed with a horse-whip, which he fortunately managed to take from his assailant's hands, but not before he had been grievously maltreated. The woman he had known for sixteen years, but had refused to treat her professionally. She was full of extraordinary delusions—as, for instance, that Dr. Fairley visited her in the middle of the night, when she was sleeping with her husband; that he (the doctor) was constantly talking into her left ear, and making suggestions to her; and that he exercised a mysterious hypnotic influence over her. The poor woman is now placed in an asylum. There could be no more typical instance of this particular kind of professional risk. The wonder is that matters were not brought to their only logical issue long before the police court stage.

Leicester and Small Pox. THE ancient city of Leicester, alas! is pluming herself upon the comparative freedom of her citizens from small-pox, in spite of the great unvaccinated population which she is not ashamed to flaunt in the face of society. A petition has been forwarded to the parliamentary Member for the borough by the local Anti-Vaccination League. It points out that the infantile mortality of the town has fallen during the past thirty years from 240 to 150 per 1,000 births. The improvement, it is claimed, is not due to vaccination, because between 1901-1904 primary vaccinations numbered only 5 per cent. of the total births, and there is now an unvaccinated child population of 60,000. The conclusion of the document is that small-pox, having failed to decimate this inflammable material, it proves that the "Leicester system" of treating infectious disease by vigorous sanitary measures is alone sufficient to exclude small-pox: *ergo*, compulsory vaccination should be everywhere abolished. We fear that one day the day of reckoning will fall upon Leicester in the avenging disaster of a terrible small-pox epidemic, and these abstract denunciations will fall to the ground like a castle of cards. Anyway, the country generally is not likely to be

led away by so foolish an example. Leicester loves anti-vaccination now as Lincoln once tolerated a bad water-supply.

The Cinematograph in Medicine.

ONE of the interesting novelties of the Lisbon Congress was the demonstration of epileptic convulsions by means of the cinematograph. The value of that modern method of graphic reproduction of living movements in medical teaching is obvious, although the field is not likely to be an extensive one. The exhibitor, Dr. William Chase, of Boston, showed pictures of no less than thirty separate epileptic seizures, whereby the action of the muscles was shown in detail. Clearly, if reference can be made to photographs registering the exact state of the muscular contractions at any given instant of an attack, evidence of value may be thereby secured, especially where localisation of the central lesion is desirable. Dr. Chase also showed a number of cinematographic pictures illustrating various gaits and other disturbed movements due to pathological changes. As these pictures can be packed in a box and despatched to any part of the world, we may hope to have an opportunity of seeing them some day in London.

Another Doyen Cure for Cancer. DR. DOYEN is not easily beaten. After a long and patient investigation, his claims to have discovered a cure for cancer have been authoritatively dismissed as worthless. That fact, however, has not prevented the enterprising physician from treating by his methods a great number of patients in Paris, and he has even extended the sphere of his activities so as to include London. The Lisbon Medical Congress has brought Dr. Doyen to the front with a new "cure" in the shape of the inoculation of the patient with the yeast of beer. The scientific world will naturally look askance at a method advanced by an observer whose previous claims have proved so unfounded. At the same time, a fair trial will doubtless be afforded to the proposed remedy. It is a matter of regret that any member of the medical profession should be found ready to spring premature announcements of this kind upon society. In Dr. Doyen's case he cannot plead inexperience, for he has had every possible sort of warning in the long series of incidents that led to the final condemnation of his "cancer serum" by the French Academy of Science.

LEADING ARTICLE.

PROFESSIONAL SECRECY.

In a letter published in the present issue of the *MEDICAL PRESS AND CIRCULAR* a correspondent calls attention to the conduct of Surgeon-Major Whiston in the recent "Ragging" case in the 1st Scots Guards. As our readers know, we have taken up somewhat firm ground as to the breach of professional ethics committed by that officer in communicating to the commanding officer of the regiment facts that had come to his knowledge as a professional confidence. The discovery that a patient had scabies can only be regarded as information of the most private and confidential kind that could conceivably be acquired by a medical man. So great is the horror with which that particular malady is looked upon generally that to proclaim any person afflicted thereby would be to inflict upon him in many cases a species of social ostracism. The question arises would an Army medical officer think it his duty to report officially that any soldier under his charge was suffering from gonorrhœa or syphilis? Those diseases are more degrading and dangerous than scabies, and are notoriously the result of immoral acts, whereas the "itch" in the vast majority of cases is contracted innocently. We have little hesitation in claiming that no Army medical officer is entitled to divulge such purely personal and private information without the consent of his patient. When medical reports are required by the War Office as to a soldier's fitness for service, that is quite another matter, for presumably both explicitly and implicitly the consent of the individual reported upon is given to the whole transaction, which is often as much to his personal interest as to that of the military authorities. It is another matter, however, when we come to purely private professional information, the divulgence of which may seriously affect the reputation and wreck the future career of some unfortunate soldier. There can be no obligation, surely, for the surgeon to inform the commanding officer of the fact that a subaltern or other soldier under him has scabies. The malady is curable within a few days by appropriate treatment, and the danger of its spread amongst persons who are ordinarily clean and decently housed is so small as to be practically hardly worth considering. That a single subaltern thus affected should spread the disease among his brother officers in a British regiment is an incredible proposition. Worse than all a doubt is thrown upon the diagnosis of scabies by the direct negative of more than one officer of the Royal Army Medical Corps. Possibly the whole truth of the incident will never be known, whether, for instance, the report as to the alleged condition of the subaltern in question was voluntarily furnished by the surgeon or under pressure from the commanding officer. In the first case we consider a medical officer acting in that way would be breaking the most sacred principles of his profession. In the second case we should

instantly condemn the action as one of military arrogance, in attempting to usurp a right to obtain special information that may legally be demanded only by a court of law. Dr. Saundby in his work on *Medical Ethics*, observes: "While members of the medical profession must obey the law, and aid the course of justice, they are not called upon to act the part of detectives or informers." We do not for a moment suggest that the Army surgeon is not, as a rule, a man of scrupulous honour. We do suggest, however, that he may at times, under pressure of military discipline or from a want of due appreciation of the unwritten laws of his profession, be unwary enough to disclose private personal matters that have come to his knowledge by reason of his professional relations with a patient. Members of the medical profession in the United Kingdom have no statutory duty imposed upon them to maintain the rule of professional secrecy, but they are bound by a higher law to maintain that honourable line of conduct which has been recognised by their predecessors since time immemorial. Evil, indeed, will be the day when the Hippocratic oath ceases to be binding upon our profession. Readers may be reminded once more of its simple and yet comprehensive terms:—"Whatever," it runs, "in connection with my professional practice, or not in connection with it, I see or hear in the life of men which ought not to be spoken abroad I will not divulge, as reckoning that all such should be kept secret."

NOTES ON CURRENT TOPICS.

The Central Midwives Board and its Relations with Ireland.

DURING the past month the Irish Hospital Matrons Association has been making strenuous efforts to induce the Central Midwives Board to hold examinations in Dublin. The Association has pointed out to the Board the manifest hardship which it causes to Irish trained nurses to be obliged to go over to London and stay there for some days in order to pass the Board's examination. In order to support their case, the Matrons Association has approached several bodies in Dublin, notably the Royal College of Physicians of Ireland and the Royal Academy of Medicine, with the request that they will also petition the Lord President of the Council and the Central Midwives Board. Both bodies were only too willing to comply with this request, but, as it was doubtful whether it was possible for the Board to act as desired, the College of Physicians wisely decided to ask for information on the point before addressing what would have been useless petitions. The result has been that the Board has informed the College that it is impossible to hold examinations in Ireland. We fear that even had it been possible to hold these examinations, the same spirit of jealousy which prompted the Board at first to refuse to allow Irish nurses to present themselves for its examinations would

have led to a similar refusal to examine nurses in Ireland. In the present case, however, there was no room for the exhibition of such a spirit, as it is evident that the Midwives Act, which applies only to England and Wales, could not be so stretched as to allow examinations to be held in Ireland. We quite agree with the Matrons' Association as to the hardship which the present state of affairs causes to Irish nurses, but we think that if it directed its energies to having an examination centre established at Holyhead, Chester, or Liverpool it would probably succeed, whereas its present request is impossible of fulfilment. It has been pointed out that the cause of the present position is the non-application of the Midwives Act to Ireland, and that some years ago more strenuous efforts ought to have been made to have it so extended. We certainly should like to see a wisely-framed Act applied to Ireland and worked under the directions of a qualified Board, but, so far from regretting our non-inclusion in the present Act, we confess to a feeling of devout thankfulness that neither the Act nor the Board has any authority in this country.

An American Form of Gout.

THE influence of race habits upon diseases forms an inviting subject for some future Darwin of medicine. Even so strangely marked a malady as gout may be modified almost beyond recognition under the transforming touch of a national environment. On the British side of the Atlantic the mention of gout conjures up the picture of red and swollen great toes, pillowed and swathed in flannel, while the luckless sufferer, ruddy and well-fed, swallows draughts countless and pills innumerable. That is the classical disease begotten of ale and roast beef and plum pudding and port wine and other excess or good cheer among our robust citizens. In America, on the other hand, the rush and hurry of life render the average individual spare and neurotic, and his gout appears to affect his whole organism with a general irritability rather than by local precipitation in the neighbourhood of the great toe and other joints. To a great extent the curious craving of our Transatlantic cousins for pies, iced water, baked beans and pork, together with over-heated rooms and "quick luncheons" accounts for the American form of gout, which, by the way, in many points closely resembles the "suppressed gout" on our side of the Atlantic.

The Wearing of Gloves at Autopsies.

WE referred a few weeks ago to the unfortunate incident at the Westminster Hospital whereby a medical student lost his life by sepsis contracted in a *post-mortem* examination performed without the protection of gloves. It would be of some interest to know whether the custom exists in many pathological departments of handling infective material thus unprotected. Judging from the evidence given at the Coroner's inquest in the case referred to, the Westminster staff have on definite grounds

abandoned the wearing of gloves. There is no doubt that the manual difficulties of the autopsy are increased by the wearing of gloves, more especially as many gloves sold for the purpose are distinctly clumsy. Moreover, as a result of the discomfort produced by clumsy coverings, there may be a greater chance of an inexperienced operator wounding his hand with needle or knife. Nevertheless, if the hands are, as commonly occurs, the site of abrasions or scratches, suitable gloves appear to offer a protection unattainable by other means. Of course, many pathologists still refuse to adopt gloves, but we think that the opinion in their favour is gradually growing. It is just as in the case of surgical operations there are still some surgeons who regard the wearing of gloves as unnecessary, although received opinion is decidedly in their favour. It is notorious, too, that medical men are not so careful where risk to their own health or lives is concerned as in that regarding the health and lives of their patients. This is perhaps the reason that the general adoption of gloves in work on the dead body lags behind the practice in surgical operations.

Sleeping Sickness.

IT is announced that Lieutenant Forbes Tulloch, one of the officers engaged in making investigations on behalf of the Royal Society in Uganda, has contracted sleeping-sickness and is to be brought back to England for treatment. In view of the invariably fatal issue of this little-understood disease, we all must hope that through some error of diagnosis or some mistake in transmission the nature of the malady is other than that reported, though we fear the hope is a faint one. Sleeping-sickness has hitherto been considered to be confined to natives, but since the discovery of trypanosomes in the blood of various Europeans and the presumption that sleeping-sickness is the result of trypanosomiasis, it has not been clear why Europeans should escape, and Lieutenant Forbes Tulloch apparently supplies a case in point. Sleeping-sickness is causing undue anxiety to the Government and English mercantile community in Uganda and British Central Africa at the moment. The disease, far from being a pathological curiosity, is now found to be infectious, probably through the medium of *glossina palpalis*, and to be spreading with alarming rapidity beyond the areas in Uganda and East Africa to which it was thought to be confined. Sleeping sickness has been met with among the natives west of Lake Tanganyika, and is reported now to have reached the borders of North-East Rhodesia, where a large susceptible population exists. The British Central Africa Chamber of Commerce and Agriculture is seriously alarmed and has made urgent representations to Mr. Sharpe, the Commissioner for British Central Africa, as to the desirability of instituting a thorough examination into the distribution of *glossina palpalis* and *glossina morsitans*—with a view to the extermination of these pests if possible. The situation is undoubtedly serious

A Year's Poisonings.

THE Registrar-General's Report for 1904 gives us some interesting information regarding the number of cases of death by poisoning which took place in England and Wales during that year. It appears that of the total of 1156 deaths, 520 were accidental, 628 suicide, and 8 murder. Of the 520 accidental deaths, no less than 161 were due to anæsthetics, and this is probably an understating of the total mortality due to this cause. The anæsthetic agents responsible were—chloroform, 92 deaths; A.C.E. mixture, 4; chloroform and ether, 3; ether, 7; ethyl chloride, 2; nitrous oxide, 5; unnamed agents, 48; it will therefore be seen that chloroform was the agent in by far the greater number of fatal cases, being employed in 99 out of 110 cases in which the agent is recorded. The number of deaths from gas is probably larger than most medical men would have expected but it is to be remembered that gas is given much more frequently by unskilled persons than any other anæsthetic. The eight murders by poisoning were committed by the aid of arsenic, belladonna, potassium cyanide, laudanum, and prussic acid. It is curious to note that whereas opiates and carbolic acid have become much less common agents of crime or suicide than formerly, oxalic acid appears to be yearly increasing in favour. There are doubtless fashions in poisoning as in other things, and a study of these would doubtless reveal many points of interest. Lead is returned as responsible for 13 deaths, a number probably much exceeded during the past year. In this connection we cannot but deplore the refusal of Lord Crewe to add diachylon to the list of scheduled poisons, since experience has shown that the scheduling of a poison has almost invariably been followed by a diminution in the number of catastrophes due to its use.

A Bloodless Duel.

WE read in the public press that Mr. H. A. Barker, whose name we seem to remember, and who is said to practise "bloodless surgery," is challenging the surgical profession to a bloodless duel. It is said that he is willing to give £10,000 to any needy London Hospital if his methods prove inferior to those of what we may term the sanguinary school. He is willing that a representative body of surgeons should submit the conditions under which experiments are to be carried out, and in the event of his triumph he only asks that his methods shall be generally adopted. All this, of course, sounds so fair that the readers of the *Daily Express*, from whose issue of April 24th we have derived our information, may be inclined to think that the orthodox profession is hopelessly prejudiced if it does not accept Mr. Barker's challenge. A moment's consideration will show that the challenge is mere "bluff." The medical profession is one that exists for the purpose of applying the best known methods and its own best skill to the treatment of patients, not for the purpose of exploiting different systems of "cure" on those who seek its advice.

In spite of the statements of some of the most virulent of hospital detractors, these institutions are not used as laboratories for experiments on men, but as refuges where the sick or maimed may get the greatest possible relief from their ailments. It is cruel, wicked, and immoral to treat any patient as the *corpus vile* of an experiment for the pleasure of demonstrating that a particular theory is wrong, unless indeed the patient is willing to be made the subject of the experiment and it is known that the experiment involves no risk to life or limb. As these conditions would not be fulfilled by the competition proposed, the "challenge" will only stir the contempt and indignation of medical men.

Insanity Problems.

THE articles on insanity that have been appearing in the *Times* will, we hope, do something to attract attention to the grave and pressing problem and give the Government the impetus needed to translate into action the conclusions that all men acquainted with the subject have long formed. The first and most important reform is that the Lunacy Commission should be immediately and substantially increased. We have much admiration for the Commissioners, who do hard work well, but no person outside the institutions that the Commissioners govern can possibly expect the work to be properly done under present conditions. Inspections have to be undertaken by the Commissioners in person, and though this is theoretically an important safeguard against the abuse of personal liberty, practically it amounts to little or nothing, owing to the hurried and infrequent visits that the Commissioners have to put in. For instance, to take a case cited, how is it possible for two Commissioners in a three days' visit to inspect a large institution and converse personally with two thousand patients? What is needed, and urgently needed, is that a good staff of medical inspectors should be appointed to act under the Commission in London, and that while the Commission regulated the general policy of lunacy administration, frequent personal visits should be made to asylums and patients under private care by these inspectors. This requirement is at the root of all reform in the present unsatisfactory state of things.

Another Hospital "Scandal."

GUY'S HOSPITAL, which does so much good work for the sick poor of London, is most unfortunate in the number of "regrettable incidents" which occur in its administration, or at any rate are boomed into copy for the press. An inquest held on April 23rd has been published at length in the leading newspapers, and has attracted a good deal of attention. It appears that the woman, the subject of the inquest, was sent up to Guy's by her private doctor because of a swelling behind the ear. The house-surgeon who saw the patient said that there was only one bed available, and that was being reserved for emergencies. In his opinion the

swelling was due to a glandular abscess, and not of sufficient urgency to justify him in parting with his last bed. The patient's husband brought the woman up the next day on instructions, and was told that the hospital was still unable to admit her. She was then taken to St. Thomas's, where her state was found to be very serious, and where immediate operation was performed. The abscess was found to be due to mastoid disease accompanied by meningitis, and the woman died fifteen minutes after the operation had begun. The jury passed a rider condemning Guy's Hospital for not having more experienced officers to examine cases for admission, and also for inadequate examination of the particular patient. As we understand the authorities at Guy's are investigating the case officially, we forbear to comment on its obvious features, beyond saying that we hope that their attention will be directed as much towards the methods in which their out-patient department is conducted as into the admitted error of judgment on the part of a junior official.

The Royal College of Surgeons, Edinburgh.

It is now nearly twenty-five years ago since we pressed upon the College of Surgeons of Edinburgh the necessity of instituting an examination for that fellowship, so as to bring that body in a line with other colleges. Feeling ran strong on the subject at the time, but now, a quarter of a century later, the College may be congratulated on the wisdom which prompted it to act up to those suggestions. The chief objection raised was that the income of the College would suffer by the change. This fear has proved unfounded, for the appreciation of the Fellowship has increased tenfold instead of diminishing. In the year 1884, the year before the change was made, the Fellowships granted were about thirty-nine. This was the largest number for many years, and was probably due to the rush to take advantage of "the year of grace." In 1903 there were sixty-seven Fellowships granted, all by examination, and Fellows without examination are so rare that within the last five years only one solitary individual signed the roll of the College by election. In the absence of direct information as to the nature of the examination or the severity of the tests we cannot speak decisively, but the rejections appear to show a fairly high standard. At a time when the question of appointing Fellows of the Edinburgh College to hospital appointments in London and elsewhere is becoming acute, it must be evident that it is an advantage to candidates to show that the Fellowship has been obtained by examination. The College must be now sincerely grateful for the far-seeing policy which has had such beneficial results, both from a pecuniary point of view and also from the increased professional status of its Fellows. In conclusion, the College may also be congratulated on the better equipment of its examining board. By the old system the examiners annually elected themselves, but that anachronism, like the election fellowship, has become a matter of history.

An Objectionable Advertisement

A FAVOURITE trick of the quack-medicine trade is to insert the name of some deceased medical man of eminence, so as to stamp some particular quackery with a false air of authority. This species of sharp practice, bad as it is, pales into insignificance beside the insertion of the names of living members of our profession. The highest conceivable flight of audacity of that kind has surely been reached by *Lloyd's Weekly News* for April 29th, 1906. On page 9 of that issue is a two-column advertisement of Page-Woodcock's pills, under the title of "Famous Consultations." It shows a portrait of the late Sir Morell Mackenzie, and another of the illustrious Page-Woodcock! The place of honour, however, is devoted to what purports to be a portrait-group of Sir Francis Laking, Sir Thomas Barlow, and Sir Frederick Treves. The nature of the remedy to which their sanction is thus indirectly implied may be gathered from the assertion that the pills in question "positively cure indigestion and all liver troubles, no matter of how long standing; also biliousness, spasms, constipation, severe headaches, heartburn, anæmia, and female ailments, as over fifty years' experience has proved, and are as valuable to men as to women." Clearly, claims of that kind are fraudulent, and merit the attention of the police. *Lloyd's News*, by inserting the advertisement, is co-operating in a scheme for obtaining money under false pretences, and by taking money for the advertisement is sharing in the proceeds. As to the outrage upon the three baronets whose names have been thus shamefully misused, we imagine that no more scathing comment could be obtainable as to the defective state of the laws regarding the patent-medicine trade. The three gentlemen implicated have no doubt a remedy at law, probably in the shape of an injunction in Chancery. That legal process, however, is costly and unsatisfactory. What we want is a short and sharp amendment of the law so as to bring the quack-medicine trade under stringent control.

PERSONAL.

THE Grand Prize of £100, awarded by the International Medical Congress for the greatest scientific work for the benefit of humanity, has been conferred upon Dr. Severan, of Paris, in recognition of his great work in isolating the malaria germ.

THE Murchison Scholarship of the Royal College of Physicians of London, founded in 1880 to perpetuate the memory of the late Dr. Charles Murchison, has been awarded to H. P. Bell Walker, M.B.Lond., a student of Guy's Hospital. The award is made alternately by the London College and the University of Edinburgh.

H.M. THE KING has granted to Dr. R. G. Kirton, principal medical officer of the Egyptian prisons, authority to wear the Imperial Ottoman Order of the Osmanje.

THE recent death of Dr. Corbett, of Droitwich reminds us of the fortunes of a remarkable family. On April 22nd, 1901, his brother, the "Salt King," and the founder of the Corbett family's fortunes, died leaving nearly a million pounds, to his brother, Dr. Corbett, and on the same day of this year, and very nearly at the same time, the death of the brother who had inherited the largest share of his fortune occurred.

A CLINICAL LECTURE ON THE DIAGNOSIS OF PNEUMONIA IN CHILDREN.

By M. G. VARIOT, M.D.,
Physician to the Hospital for Sick Children, Paris.

(Specially Reported for this Journal.)

THE clinical study of pneumonia in the child deserves consideration because of its frequency, although seen in infants it is more frequently met with in children between two and three years of age. The accidents that accompany the pneumonia of childhood are frequently alarming, not only to the doctor but also to the parents, for the case invariably appears worse than it actually is and sometimes, at the outset, it is impossible to arrive at a diagnosis. I remember seeing a little girl, 22 months old, who was admitted into the ward with the following history: She had been ailing for four days, being feverish, with loss of appetite. The evening temperature varied from 104° to 105·8 F., and in the morning from 99·8 to 100·5. The daily oscillations were not at all typical of lobar pneumonia, besides which there was no cough, the respiration rate was not accelerated, and, on the whole, there was no theory to lead one to suppose that the lungs were involved.

On examining the chest some impairment of resonance was noticed in the left supra- and infra-spinal fossæ, with tubular breathing and bronchophony in the left axilla. The signs remained localised and unilateral, so that we diagnosed a lobar pneumonia, in spite of the absence of symptoms and the irregular course of the temperature. It is not at all uncommon to find oscillations of 4° or 5° F. between the morning and evening temperature in the pneumonia of infants, and, moreover, on the fifth or sixth day a drop occurs, suggesting a crisis, but it is only temporary, for the fall is succeeded on the following evening by a temperature as high as before or even higher. This rise does not correspond to a fresh pneumonia focus, for after one or two such oscillations the temperature settles down to normal, or may even be subnormal on several subsequent days. It is, however, unusual for these oscillations to persist during the whole course of the disease.

Last year I was called in consultation with two colleagues to see a boy, five years old, who had oscillations of 3° and 4° F. for six days, although the most careful physical examination of the different organs failed to reveal anything abnormal. I tried to examine the child's chest, but patient was so refractory that it was extremely difficult to make out anything. I thought, however, at the time there was some impairment of resonance in the infra-clavicular region, so I risked the diagnosis of a central pneumonia. It was supposed that the fever might be due to some gastro-intestinal disturbance, or to some intermittent quotidian fever, but two days later I heard from the doctor in charge of the case that a patch of bronchial breathing had appeared on one side of the chest, thus confirming my diagnosis. These facts tend to show how difficult it is to diagnose pneumonia in a child, the difficulty being still further enhanced by the impossibility of making a proper examination.

The contrast between pneumonia in the adult and the infant is striking, for in the former the diagnosis usually presents no difficulty whatever. The functional trouble and the physical signs giving a well-defined clinical picture; whereas in infancy it is liable to run an abnormal course, so that the clinical picture is incomplete and the interpretation of the symptoms and signs is most laborious.

In the adult the onset is sudden, with a rigor, pain in the side, vomiting, cough with typical expectoration even in the cases of central pneumonia, dyspnoea, temperature of 104·2 and well-marked physical signs together with a definite history which can be elicited from the patient. In children under three any one of these signs and symptoms may be lacking—has the child had a rigor? One cannot be certain of it; the pain in the side must frequently be absent, for the dyspnoea is less marked than in the adult. In children of five or six years of age this pain in the side is more constant, though they do not always localise it in the chest wall but refer it to the abdomen or to the right iliac fossa, so the pain, vomiting, and temperature make the case resemble one of appendicitis, and it frequently happens that these patients are sent into surgical wards by mistake.

I recall one case vividly—that of a little patient who for three days had suffered from uncontrollable vomiting, accompanied by severe pain in the abdomen and a temperature of 104°, with rigidity of the abdominal wall. The vomited matter was partly bilious and of a light green colour, so that the medical man thought he was dealing with a case of peritonitis. On auscultation I discovered a localised patch of bronchopneumonia in the axilla. This turned out to be a case of pneumonia which has been called "emetic," because of its association with reflex vomiting.

But let us come back to the point of contrast between pneumonia in the adult and in the child. Dyspnoea is almost constant in the pneumonia of adults, the respiratory movements are increased in frequency, difficult and painful. In infants dyspnoea and increased frequency of respiration are less constant, in fact, they are sometimes entirely absent, while the respiratory rate of 30 to 40 may be due simply to hyperthermia and independent of any affection of the respiratory apparatus. In cases of double pneumonia, and in children of ten and upwards, the dyspnoea may be very intense. Still we must not rely on this functional trouble to establish the diagnosis. The great rapidity of the respiratory movements in a bronchopneumonia is more or less constant, therefore it is a valuable sign in the differential diagnosis.

The cough during the first couple of days of the illness in the child is frequently absent or so insignificant as to escape attention; it is in the latter part of the illness, when the physical signs reach

the surface of the lung, that the cough becomes more troublesome.

The expectoration is the most constant and characteristic symptom in the adult, and when this is rusty or the colour of plum juice the diagnosis is certain. But here again no sputum can be obtained from an infant. In the course of five years in only three out of 300 cases of pneumonia have I noticed this rusty sputum in patients under twelve years of age. Must we, therefore, give up the idea of examining the expectoration of a child in whom we suspect a central pneumonia? As a matter of fact this examination is not so troublesome as might at first sight be supposed. It has been proposed to evacuate the contents of the stomach for this purpose, but the same end may be attained more readily. It is only necessary, by means of a tongue depressor, to touch the walls of the pharynx, this will make the patient cough and the sputum will be seen at the back of the throat, when, by means of a tampon of cotton wool, it can be collected. This little manœuvre is almost invariably successful and can be repeated without inconvenience. We have been able in this way to obtain sputum which could be examined for the pneumococcus, so settling the diagnosis.

Hyperthermia is in reality the most constant accompaniment of the pneumonia of infants. I have already mentioned the irregular temperature curves, characterised by great oscillations which give so much trouble to the doctor, these fortunately are not the rule. As a rule the temperature rises suddenly to 103° or 104° F., with small oscillations between morning and night, and remains so for five or six days, the crisis occurring between the fifth and seventh days. The temperature, however, may remain up longer than this with more or less pronounced remissions—this form is not at all common. If the temperature remains up in this way after pneumonia, we must always bear in mind the possibility of the development of an empyema and examine again and again very carefully. In fact, the temperature may be the chief symptom that reveals an infantile pneumonia, with its usual concomitants—gastric disturbance and prostration. If the pneumonic area is limited and not larger than a tangerine orange, if it remains central, the physical signs may be so poorly developed that the diagnosis remains uncertain for five or six days—it only becomes certain when a crisis occurs.

In a febrile illness with digestive and nervous troubles, with an absence of physical signs in the lungs and no dyspnoea, a diagnosis of enteric fever suggests itself, and if at the same time there is repeated vomiting, with convulsions at the onset, followed by delirium or unconsciousness, the picture looks very much like one of meningitis. Moreover, Widal's reaction does not help us in the diagnosis at this early stage, so that often the ordinary practitioner overlooks an early infantile pneumonia.

Rilliet and Barthez describe a cerebral pneumonia, which may be either eclamptic or meningitic according to the predominance. In convulsions or coma one meets with the utmost difficulty in arriving at a diagnosis, partly of course on account of the impossibility of properly examining the little patient. I remember one case in particular where I was called in to see a little girl of seven, who had an acute otitis of two days' duration, and

who was under the care of a specialist. After the last visit of the specialist, the temperature rose suddenly to 104° F., and the child became delirious and unconscious. A surgeon was called in, who diagnosed the onset of meningitis to the consternation of the parents. In the course of the evening I saw the child, who was unconscious, and had rigidity of the muscles of the neck, the eyes were fixed, the pupil contracted but equal, and the temperature 104° F. I examined the chest as carefully as possible under the circumstances, and though the result of auscultation was negative, percussion revealed a very slight impairment of resonance below the right clavicle. There was no dyspnoea and no alteration of respiration—the child in addition had been sick several times. I made a lumbar puncture and withdrew five or six grammes of a clear, limpid fluid, which on examination showed nothing abnormal, so I was of opinion that the case was one of a central pneumonia taking a meningitic form, and told the parents there was still hope. The following day the symptoms became more severe, in spite of cold baths and the application of leeches to the mastoid processes, the child screamed, ground its teeth, and refused all food. Three days after my first visit, there was a convulsion followed by coma. I was called in once more though by then all hope had been abandoned by the parents. The pulse was strong and regular, the left arm and leg were spastic and as the child was noisy and delirious, I ordered a hypodermic injection of 1-12th of a grain of morphia, which had a wonderful effect, succeeding where every other means had failed. The child slept for five or six hours, and on waking was able to recognise the persons round the bed. The following day a patch of bronchial breathing was heard in the upper lobe of the right lung, so the diagnosis was settled. This shows how much earlier percussion indicated the part affected. The lesion cleared up in the ordinary way.

The differential diagnosis between the pneumonia of infants and the various forms of cerebrospinal meningitis is even more difficult than that of tuberculous meningitis, and in connection with this I may recall a baby, 14 months old, whom I saw in consultation with the family physician. The patient had a temperature of 104° F., which remained high without oscillations; in spite of an absence of physical signs, we thought of a central pneumonia, but later the advent of repeated attacks of vomiting, convulsions, and papillary troubles left no doubt as to the diagnosis and its fatal prognosis.

In examining the child, try to distract its attention by a sweet or cakes, place the patient on the back with a small pillow under the head, this manœuvre renders the infra-clavicular fossæ more prominent. Lightly percuss the clavicular regions on both sides, and often you will notice an impairment of the note on the side of the lesion—in children the apex is the seat of election—but sometimes the note is tympanitic over the affected area, due to the development of compensatory emphysemas. On auscultation the breath sounds on the healthy side appear feeble in comparison, so that it is quite easy to make a mistake as to which side the lesion is.

I wish to lay stress on the importance of percussion, because it reveals the nature of the case two or three days before auscultation comes to

our aid, and sometimes even is the only sign indicating a pulmonary lesion. It is useless in infants to rely on finding vocal fremitus, but tubular breathing, bronchophony and crepitations may be heard, and then, of course, there is no more difficulty in diagnosing the case than in adults. But often only one or more of these signs may be present. In 1898 Chicotat found that it was possible to identify a patch of consolidation in the lung by means of X-rays—a means of great importance when physical signs are wanting.

The foregoing clinical details show that it is quite easy to distinguish between a lobar pneumonia and a broncho-pneumonia dyspnoea, acceleration of the respirations which may reach 70, 80, or 90 a minute, and the cyanosis is more marked in broncho-pneumonia. The physical signs are bilateral, no impairment of resonance can be detected on percussion, but auscultation reveals fine, moist crepitations on both sides accompanied or not by patches of bronchial breathing. Radioscopy does not help in these cases.

The diagnosis, however, becomes difficult if the case is one of double pneumonia, and the pseudo-lobar form of broncho-pneumonia presents many points of resemblance to the preceding variety, and it is more by the evolution of the disease than by the help of the physical signs one can settle the question. In difficult cases the bacteriological examination of the sputum should be made, and I am of opinion that the presence of the pneumococcus renders the prognosis more favourable, although the areas of consolidation may be bilaterally distributed.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of the journal. The lecture for next week's number will be by John Lindsay Steven, M.D., F.F.P.S.G., Physician and Lecturer on Clinical Medicine, Glasgow, Royal Infirmary, on "General Cystic Degeneration or Transformation of the Kidneys in the Adult."

ORIGINAL PAPERS.

THREE CASES OF UTERINE MYOMA.*

By ARTHUR E. GILES, M.D., B.Sc., F.R.C.S.,
Surgeon to Out-patients, Chelsea Hospital for Women and Gynaecologist to the Tottenham Hospital.

THE three specimens to be discussed here have this in common—that they are all cases of uterine myoma; apart from this feature they present widely different clinical and pathological features; but it happens that all three were operated on within a month.

CASE I.—*Uterine Myoma with Suppurating Carcinomatous Ovarian Cyst.*

In September of last year Dr. Kenneth Frazer, of Eastbourne, sent up a lady to see me with the following history.

Miss G., æt. 37, suffered from abdominal pain which came on in the form of "attacks." There had been three such attacks, namely, in January, June, and August, 1905. Each attack began with a sense of dragging all over the abdomen, followed by acute pain in the right side. Since June, pain had been constant, extending from the abdomen to the right groin and hip. The patient suffered from constipation, which was more pronounced during the attacks; after an action of the

bowels the pain was easier. Leucorrhœa came on in June, giving place to xanthorrhœa at the end of July. Menstruation was regular; the loss was moderate and diminishing, and was not associated with any special pain. On examination of the abdomen, a hard tumour was found, rising nearly to the umbilicus; it felt fairly smooth and uniform. The breasts were normal, and contained no secretion. On vaginal examination a tumour was felt, apparently part of the tumour felt by the abdomen; it seemed to be a single tumour connected with the uterus. The cervix was normal; no softening, but the external os was slightly patulous. The uterine appendages could not be distinguished. A diagnosis of uterine myoma was made, and operation was advised. This was carried out at Eastbourne, with the assistance of Dr. Frazer, on October 6th.

On opening the abdomen it was evident that the case was not so simple as I had supposed. The uterus was the seat of several myomata; but the greater part of the swelling consisted of a right-sided ovarian cyst so closely adherent to the uterus as to be almost incorporated with it. The left tube was salpingitic. The operation was rendered very difficult by dense adhesions between the sigmoid and upper part of the rectum, and the back of the uterus and cyst; and when these had been separated, the sigmoid was completely stripped of its serous coat for a distance of three inches. The cavity of the bowel was, fortunately, not opened. The uterus with its tumours, the ovarian cyst and the left appendages were all removed. I had some fear that the patient might develop a faecal fistula, and left a gauze drain in the pelvis, in case of accidents. The nurse was instructed to use the greatest caution in the administration of enemata. Cases in which the nature of the operation leaves one with the gravest forebodings as to the patients' progress have sometimes a pleasant way of giving no trouble at all; and so it proved in this case, as the patient made a rapid and uninterrupted recovery.

On opening the cyst immediately after the operation I found that its contents were suppurating; and my anxiety about the patient's welfare was further increased when I received the following report from Dr. Easte's laboratory:—

"The wall of the large cyst contains some solid adenomatous material with a malignant distribution. It is much inflamed, and consequently mixed with granulation tissue. No tubercle is to be found in the latter. The cyst appears to be of ovarian origin. The parametrium in front of this large cyst contained a suppurating body the size of a Kentish cob-nut. It resembled an oval lymphatic gland in appearance. Microscopically it is made up of fibrous tissue, granulations, and carcinomatous cells. A second body similar in all respects but less degenerate and purulent was shelled out from the same situation, and in this there is a good demonstration of a secondary deposit of tubular carcinomatous cells. From the back of the uterus, low down, two degenerate masses were removed and examined, and both these prove to be degenerate cancerous metastases. Note.—The distribution of the adenomatous tissue in the wall of the large right-sided cyst suggests malignancy. This, therefore, is no doubt the seat of the primary focus."—(Signed) C. L.

I saw the patient two months after the operation

*Paper read before the British Gynaecological Society, April 9, 1906.

and she was then looking and feeling well ; and I have not so far heard of any recurrence.

The association of ovarian tumours with uterine myomata is interesting and not very uncommon ; of 124 cases of uterine myoma dealt with by abdominal operation, 12 cases or 10 per cent., presented this combination. The ovarian tumours were as follow : Cystic adenoma, 5 cases—one of which had a twisted pedicle ; dermoid, 1 case ; cystic adenoma on one side and dermoid on the other, 1 case ; fibroma, 1 case ; papilloma, 2 cases ; carcinoma 2 cases, including the present one. The other case of ovarian carcinoma was also a single woman, æt. 38, and the operation was done exactly a year ago (April 10th) ; I have not heard of any recurrence in her case.

CASE II.—*A Large Cervix-Myoma.*

On September 24th, 1905, Dr. W. H. Slimon asked me to see with him a lady with the following history :—

Mrs. S., æt. 32, had one child, 5 years ago. Six months after the confinement she noticed an increased menstrual flow, which became progressively more abundant up to the present time. The periods now last 10 to 15 days, and are followed by great exhaustion for a few days. Two years ago she noticed that the abdomen was enlarging. She consulted Dr. Slimon on September 15th, when he noted that she was a stout florid woman of medium height, who slept well, and was able to walk well once the exhaustion following menstruation had passed off. The bowels acted regularly, urine normal, with sp. gr. 1020. On examination a hard mass could be felt, rising out of the pelvis as high as the umbilicus. The uterus could not be differentiated from the mass. On vaginal examination the cervix was thinned out and the external os dilated over a hard mass which was continuous with the tumour felt per abdomen. The pelvis appeared to be quite filled up by the tumour. Dr. Slimon diagnosed uterine myoma, and when I saw the patient I confirmed the diagnosis, and we agreed in advising an operation which was undertaken the following day. On opening the abdomen the tumour presented. On the summit of it was the body of the uterus, somewhat flattened down over the tumour ; the tubes ran out at the sides, well above the main part of the tumour, and both of them were dilated, with sealed abdominal ostia. It was evident that we had to deal with a large cervix-myoma impacted in the pelvis, and it was quite impossible to raise it out of the pelvis. The distal portion of each broad ligament was therefore clamped and divided between the clamp and the tube ; and the divided portions of the two sides were connected by incisions through the tumour-capsule, in front of the uterus and behind it. By shelling out the tumour from the lower portion of the capsule the whole thing could be raised out of the pelvis and the tumour was then removed by a pan-hysterectomy. The vaginal vault was brought together by mattress-sutures and the peritoneum united over the stump. The patient made an uneventful recovery and went home on October 11th, being the sixteenth day after the operation.

Cervix-myomata are an interesting variety of myomata, whose chief characteristics were first fully dealt with by Mr. Bland-Sutton. He found that they formed about 5 per cent. of uterine myomata, and my own more limited experience

is in harmony with this, as out of 124 cases of uterine myomata dealt with by abdominal operation, five were cervix-myomata. At one time the removal of a cervix-myoma was regarded as a very formidable matter ; but the principle of enucleating the growth to start with has greatly simplified the procedure, although even now, as in the present instance, the operation may be a difficult one. When the old clamp method was in vogue, a cervix myoma was an irremovable tumour.

It is a point of some interest that in this case, in spite of the fact that the tumour practically filled the pelvis, there was no disturbance of the bladder and bowels. This is partly explained by the curious fact that while these tumours mould themselves so as to form an almost complete cast of the pelvis, the sigmoid appears to have the faculty of making itself respected by the tumour ; and there is always found on the left posterior surface of the tumour a flattened area corresponding with the space occupied by the bowel.

CASE III.—*Intra-Uterine Myoma Removed by Abdominal Myomectomy.*

The case was that of a nurse, æt. 36, single, who had suffered from menorrhagia for over two years before operation. She had been curetted with only temporary benefit. I had her under treatment for fifteen months ; at first the uterus only presented a moderate enlargement, but it gradually increased in size ; and it was evident that a definite myoma had developed. The uterus was quite uniformly enlarged, and I came to the conclusion that there was a single intra-uterine myoma which could probably be removed by myomectomy, leaving the uterus behind. I operated in September of last year. On opening the abdomen the large globular uterus presented, and I at once made a median incision over the anterior wall, opening the uterine cavity, and removed a myoma, the size of a large orange. The uterine wall was sewn up again as after a Cesarean section. The patient made a good recovery.

The interest of the case lies chiefly in the operative procedure, which was an abdominal intra-uterine myomectomy, or, as it has also been called, hysterotomy. I have done this operation three times in twenty-four myomectomies. The first case was a young single woman, of twenty-three, and I reported the case in the "Obstetrical Transactions" for 1900 ; up to that time I could find only very few cases reported.

SOME REMARKS ON UTERINE SUSPENSION AND SHORTENING ROUND LIGAMENTS.*

By JAMES S. ASHE,

Professor *Materis Medice*, Ph.S.I. ; Gynaecological Assistant, Adelaide Hospital, Dublin.

I HAVE chosen as the subject of this short paper the cases of uterine suspension and shortening of round ligaments which have come under my notice as clinical assistant to Sir Wm. Smyly, at the Adelaide Hospital, to whom I am indebted for his courtesy in allowing me to write on his cases.

Having diagnosed retro-versio flexion, the question we have to face is this, Are we dealing with a case for palliative or radical treatment ? For I firmly believe cases are operated on which need

* Paper read before the Obstetrical Section of the Royal Academy of Medicine in Ireland on April 6th, 1906.

not be, and cases which should be operated on are let run too far or left over altogether. I have looked up a lot of authorities on this matter, and, in my humble opinion, Jellett states the case more concisely and to the point than any of the others I have seen. He says:—"Palliative treatment is at first indicated in all cases, as it may bring about the cure of the condition." Under this heading I would be inclined to group (1) those cases which are accidentally discovered and cause no apparent symptoms, these cases ought, of course, to be left severely alone; (2) those post-parturition cases which are due to atonic relaxation of the ligaments; (3) and those similar cases which are seen after long illness, such as typhoid and the fevers generally. This class of case does very well with a pessary, tonic, and change.

There is a class of cases which I have not yet seen described which may be tried under this heading, but usually fail. Those congenital or hysteroptotic cases which are associated with enteroptosis of the abdominal organs generally, and which run in families—I have seen two sets of sisters thus; and again, those cases which I would describe as resilient uteri, which, having put into position and inserted a pessary, keep returning to a mal-position and mean operation probably later.

"Radical treatment is indicated" (and I still quote Jellett) "(1) When no pessary will be found which will keep the uterus in position." Those resilient and hysteroptotic cases I have mentioned. "(2) When the pessary causes discomfort and vaginitis"; and I have noticed a peculiar kind of vaginitis which goes with pessaries, the mucous membrane has a mottled appearance like a piece of Castile soap, the discharge thin and watery, and the sensation described as burning; the condition rapidly improves on taking out the pessary and putting in glycerine and ichthyol plugs for a few days. "(3) When the patient cannot pay the necessary periodical visits"; those cases which are going to some out of the way place abroad, and also under this head may be grouped the poor, such as frequent our dispensaries, who cannot find time to come regularly and be looked after, and who are willing to undergo an operation and be done with it.

This classification does not say anything about time and duration under the palliative treatment, and which has to be left to the discretion of the gynaecologist and the merits of each case.

We now come to the question of operation. Are we to do shortening of round ligaments or a suspension? The former, of course, seems the more natural and lessens the subsequent danger (?)—and I put in a note of interrogation here—if the patient becomes subsequently pregnant as against suspension of the uterus by Howard Kelly's method. Now, from what I have seen I think suspension the more reliable, less difficult, and shorter operation, and I wish to state from what I know anatomically and clinically no operator can definitely say, "I will shorten the round ligaments in this case and give a good prognosis." Why? Because the result will altogether depend on the state the round ligaments are in, they may be badly developed or attenuated, and this cannot be diagnosed till they are seen. I have seen them normal on one side and attenuated on the other, so on these grounds Alexander's operation can never be a certainty, for if small and attenuated

the ligaments will stretch and the retroversion occur.

So perhaps the best rule would be to operate with an open mind, use the usual abdominal median incision if the patient be young and likely to have a family, and the round ligaments well developed, give her the chance and shorten them in the manner I will describe later. If the ligaments are not suitable, do a suspension.

Now to comment on those cases which were operated on at the Adelaide Hospital last year.

In doing uterine suspension the incision is always the mesial one, no muscles are cut, the transverse incision has been given up as limiting space too much, and one can never absolutely make certain that a retroversion will be the only trouble found, and it hampers matters too much under such circumstances to have too limited space. Sir Wm. Smyly used as suspensory ligature silkworm gut, two of which are usually passed transversely through the anterior and upper portion of the fundus; closure of the abdominal wound is carried out by a slight modification of Kelly's method; of nine such cases they all had an aseptic recovery. I have seen six and they are in perfect health, as are the other three who wrote to me from the country in answer to my inquiries. This is certainly a record that cannot be beaten—cure 100 per cent. I may mention in passing that Howard Kelly's percentage was 99.

VAGINAL HYSTEROPEXY.

Three such operations were performed, in one the retroversion has recurred; another I have seen and she is all right, and a third writes from the country to say she is in excellent health—cure in 66½ per cent.

SHORTENING OF ROUND LIGAMENTS.

This was in all cases done by the abdominal route, and Sir Wm. Smyly combines Wylie's and Dudley's methods. Wylie, of course, seizes the ligaments in the middle and pulls them out, vivifying the opposing parts of the ligaments, then passes three encircling cat-gut sutures. This is a mistake, I think, in two ways. First, there are more ligatures than necessary; secondly, the danger of the stump sloughing, so that one good ligature which will perforate both ligaments is to be preferred.

Dudley's operation slightly differs from this; he vivifies the anterior surface of the uterus and stitches the ligaments with cat-gut. The method adopted at the Adelaide Hospital, you will see, is a modification of both, instead of pulling the ligaments out, as in the case of Dudley's operation, they are drawn in, but before this is done the ligaments are seized with a forceps as near the internal abdominal ring as possible and the ligament put well on the stretch, and again as near the cornu of the uterus as possible; when these forceps are brought together there is a loop of round ligament formed which can easily be drawn in and a perforating cat-gut ligature applied; the same is done on the other side; now we have the two free genu or "sheep shanked" ligaments to deal with and the chief essential is done, the ligaturing of the genu together and then to the anterior and upper portion of the uterus. I hope you will understand my meaning from the diagrams on the board.

Of six such cases three have been quite satisfactory; one has again retroverted (and I may mention at the time of the operation it was

remarked what attenuated round ligaments they were). Of the other two both have cystic trouble. One of the cases cannot retain urine for more than thirty minutes at a time and finds it very trying, for she is in business; the other case is not so bad. I have examined the urine of both sent up to me from the country and am afraid the first case must be put down to cystitis; this is not to be wondered at, as she had to have a catheter passed every day during her convalescence, and only had it discontinued just before leaving. The other case of this nature may prove interesting. It may be due to pressure of the pulled forward uterus on the bladder when it is filling, and we hope to have this case examined later on cystoscopically.

I would like to ask any of the Fellows of this Section, Have they noticed any after trouble in cases of shortening of round ligaments? Also what are their experiences in cases which have afterwards become pregnant when abdominal suspension has been performed, as from what I know now as regards both the operations I would prefer to do a suspension, if such were required, to shortening the round ligaments, the latter, in my opinion, being a longer, more difficult, and tedious operation, and which from all statistics does not give as good results as those done by suspension.

A NOTE ON SUPRAVAGINAL AND PANHYSTER- ECTOMY: WITH THREE OPERATION CASES.*

By FREDERICK EDGE, B.S., M.D., F.R.C.S.,
Surgeon, Birmingham and Midland Hospital for Women.

In the course of further experience there is a natural tendency to change, and I have been no exception to this tendency. I had a strong predilection for panhysterectomy at first, but gradually came to favour supravaginal hysterectomy more and more. During the last twelve months I have had two deaths after supravaginal hysterectomy, which have profoundly impressed me that the operation has a more limited field than I held it to have.

The first case was one of secondary hæmorrhage when the left ovarian vessel bled, although the pedicle was ligatured twice at the operation. The abdomen was opened and the vessel found with slack ligatures on it. It was re-ligatured, but owing to the severity of the primary operation, when there was much loss of blood from adhesions, and the great loss again the patient died.

I shall not discuss this case except in so far as it relates to the method of operation. Had panhysterectomy been adopted I think that the secondary hæmorrhage would have shown itself per vaginam, and intervention would have been much earlier and with better chances of success. The question of how much drainage, by keeping the parts dry, tends to prevent secondary hæmorrhage also enters here. It may be said that an opening through the pouch of Douglas would have served to drain and to give early warning of secondary hæmorrhage, but I question this if the opening be plugged with iodoform gauze or if the bleeding were subperitoneal.

The second death was almost as tragic. I per-

formed supravaginal hysterectomy for pelvic deformity at term. The patient did well for five days, when the pulse rose to 110, and temperature to 101° and 102°, I did not feel alarmed as I put the fever down to cellulitis about the cervix and ligatures. However, next day symptoms of acute general peritonitis ensued and the patient died on the tenth day. *Post mortem* there was marked purulent peritonitis which had arisen from a left broad ligament abscess, and instead of this abscess opening into the vagina it had flooded the peritoneum. I shall not discuss where the sepsis came from. Suffice it to say that on the same morning I had done a similar case (cases of like character seem to come to the surgeon in pairs), which recovered without any sepsis or peritonitis. Either sepsis was present in the second case or was introduced. The same procedure was adopted in each case and the cervix was closed with fine silk sutures. The peritoneum being stitched continuously from side to side. I feel that, had this case been treated as a breast case with free drainage, she would have stood a good chance of recovery, after perhaps a tedious convalescence with free suppuration.

This question of local and general peritoneal sepsis and infection of the peritoneum has not been sufficiently pressed. The question of malignant degeneration of the cervical stump has occupied too much of the ground; but I feel that the immediate trouble of sepsis will eventually have more weight in deciding the balance between the complete and the partial operation than any fear of malignant degeneration.

Our President has several times expressed the view that it is not wise to close the cervical canal, and that one often regrets not having drained but very seldom regrets having used a drain for some hours. Dr. Macnaughton-Jones records a case where the whole cervical stump sloughed away, happily with no evil effect.

Mr. Bland Sutton employs panhysterectomy in cases where sepsis may be present as in parous married women, when the patient is over forty and cancerous degeneration of the stump may follow, while he reserves supravaginal hysterectomy for cases with a long cervix in spinsters and nulliparous married women. Quotations may be multiplied, but these occur to my mind.

In the case of the specimen of myomatous uterus shown I removed the posterior half of the cervix and, in future, I shall always leave free vaginal drainage by operating as follows: The vagina is thoroughly disinfected and the cervix seized and cleaned out. An incision is made posterior to the cervix and parallel to it, but not opening into the pouch of Douglas. A sterilised compress is inserted into this incision as a point to aim at from above. The abdomen is then opened and the myomatous uterus drawn out if possible. The ovarian and round ligament pedicles are ligatured, leaving plenty of peritoneum. The anterior peritoneal flap is carried well up the anterior uterine wall, so as to get a good large flap. The posterior flap runs from one ovarian pedicle to the other and is dissected down before the uterine arteries are tied, as otherwise the peritoneum is apt to be caught by the ligatures. The uterine arteries are then tied and a second ligature on each side takes up branches to the cervix and vagina. Now the vaginal compress

* Paper read and cases shown at the British Gynecological Society, April 9th, 1906.

is cut upon and the cervix removed, either before or after supravaginal section, as is found convenient. The pedicles are all turned in and the peritoneum sutured from side to side, a drain being inserted previously into the vagina. In this way the wound is shut off from the peritoneal cavity and every part of it is freely drained. Any secondary hæmorrhage will show at once as in vaginal hysterectomy, and any pus will have a free outlet. The final result is practically the same as in Doyen's classical method, but this method can be applied to all forms and situations of the myomatous uterus. Even if one case in a hundred be saved by this method it will be justified.

SPECIMENS.

(I.)—*Strangulated Myoma of the Uterus simulating Cancer of the Fundus.*

This case was seen by Dr. Lycett, our local secretary in Wolverhampton, and as there was such a strong family history of cancer it was feared that cancer of the uterus was present, although the symptoms pointed to strangulation of a tumour in the pelvis. The cervix had an expanded feel, which ran into a rounded mass in the pouch of Douglas. I have had three cases of cancer of the fundus in elderly women when the fundus was retroflexed and felt like a myoma in the pouch of Douglas.

I extract from Dr. Lycett's notes as follows :—A.S., æt. 58, unmarried, menopause at 50. Previous history good. Father died of cancer of stomach, and an aunt died of cancer of bowels. Patient has suffered from slight pelvic pain this winter, but nothing severe until after a walk on February 23rd, when she was seized with acute pelvic pain. Dr. Lycett saw her next day with Dr. Crear. She had severe pain in the lower abdomen, pulse rate 120, and temperature raised, 104° was the highest. There was no vomiting. A full examination was impossible owing to tenderness, but the uterus was felt fixed and a mass in the pouch of Douglas and to the left. The cervix was thick and expanded. Although the symptoms pointed to axial rotation of an ovarian cyst, carcinoma was not excluded, as the lump was so small and intimately united with uterus, and the family history was so suggestive. With rest she improved, and on March 22nd I saw her with Dr. Lycett when my opinion was that an exploratory operation would decide between cancer, myoma, and twisted ovarian cystoma, with possibly a complicating pus tube. On March 23rd the abdomen was opened and dense adhesions found in the pelvis. These were separated carefully and the appendages were traced out and found adherent, but healthy. The fundus was retroverted and seemed globular. By insinuating my finger cautiously down the back of the right broad ligament I felt the hard rounded myoma, and it was now evident that there was no danger of rupturing any foul cancerous growth. The sphacelated myoma was removed and two small myomatous nodules also. It is difficult to convey views held in the midst of operating, but I should like it to be clearly grasped that the pelvic viscera were so glued together that at one period I considered I was running great risks of doing more harm than good, and perhaps of needlessly hastening the end by breaking down protective peritoneal adhesions such as I have seen in cancer of fundus or rectal wall. The convalescence has been uninterrupted. I have seen fatal sepsis

from strangulated sloughing myomata, and as this was so adherent to the rectum it is probable that infection would have taken place.

Dr. Crear wrote after the operation :—"I thank you for your letter. I was very pleased everything had gone on so well and especially pleased to know there was no malignant growth. The presence of these small growths explains the expanded feel of the cervix all round in addition to the larger mass posteriorly."

(II.)—*A Pregnant Uterus with an almost Sessile Myoma removed by Supravaginal Hysterectomy.*

Patient, æt. 45, with history of amenorrhœa for three months. The patient had severe abdominal pain and on examination a large hard mass, continuous with a cystic globose uterus, was found. Torsion of a myoma or ovarian cyst was diagnosed. The myoma was found intimately adherent to bowel, and after this had been separated and several small arteries tied on the bowel surface the myomatous base was ligatured with No. 5 silk as this seemed quite feasible. However, the suture cut through the soft uterine tissue and opened the venous sinuses. I have often removed ovarian cysts and several pedunculated myomata from pregnant uteri without interrupting pregnancy. In this case I found the uterine bleeding difficult to check and decided that removal of the uterus was the safer procedure, especially as the patient had expressly desired the uterus and ovaries to be removed so as to be rid of any chance of future disease. It was not my intention to do so, but as things turned out I was compelled to satisfy her wishes. This case was sent by Dr. Lycett and Dr. Bard.

I have generally made flaps from the myomatous capsule in such cases, but in this case the myoma had an irregular knotty surface and sarcoma was suspected. It has not yet been examined.

(III.)—*A Myomatous Uterus with Expanded Cervix removed by Abdominal Hysterectomy.*

The cervix was removed after supravaginal hysterectomy, but not entirely, as the anterior wall was left. This specimen is merely shown as a sample of those cases in which I consider free vaginal drainage essential, because the wound surface is so large and so vascular that, however carefully hæmorrhage is carried out, I think that the oozing is likely to be more than can be safely left in a closed wound or trusted to the absorptive capacity of the peritoneum.

CLINICAL RECORDS.

CASE OF ECTOPIC GESTATION.

UNDER THE CARE OF J. COTTER, M.D., R.U.I.,
M.Ch., F.R.C.S.,

Senior Surgeon, Cork North Infirmary, &c.

MRS. L., æt. 36, married nine months. Menstruation was regular up to November 20th, when she missed a period then due. A week after this the period came on, heavier than usual, and lasted four or five days. On December 4th, she experienced severe pain in the lower part of abdomen, and felt as if something had given way inside. She got very faint and vomited. A week after a swelling in the lower abdomen appeared, which gradually increased. When first seen by him she was profoundly anæmic, with raised temperature, and pain in the lower abdomen, where there was a fluctuating tumour. Per vaginam fluctuation could be felt over a swelling in Douglas's pouch, and the uterus was pushed forward. He operated on December 24th.

first tapping the tumour through the posterior fornix, and got nothing but pure blood. The abdomen was then opened by mesial incision, and what looked like a large ovarian cyst immediately presented. On opening it a large collection of blood, fluid and clotted, escaped, the clots being ladled out with the hands. At one side of the cyst wall, somewhat in the situation of the outer end of the left Fallopian tube, was what appeared to be a lump of organised lymph. Portion of this was removed, and Dr. Moore reported that it showed chorionic villi, and decidual tissue. The cavity was packed with iodoform gauze, and recovery was uninterrupted.

Dr. Cotter remarked on the great rarity of such cases, and thought that this was a tubal abortion, as there was no evidence of a rupture of the tube.

THE OUT-PATIENTS' ROOM.

KING'S COLLEGE HOSPITAL.

Tuberculous Glands of the Neck.

By Mr. PEYTON BEALE, F.R.C.S.

AMONGST the out-patients was a boy, *æt.* about 15, suffering from enlarged lymphatic glands of both sides of the neck. The history of the case was as follows:—When seven years of age the boy suffered from measles followed by bronchitis, during which he expectorated some blood on two or three occasions. At this time it was noticed that his glands were somewhat enlarged, and as there was a very well-marked tuberculous family history it was assumed that he was suffering from phthisis, and that the enlarged glands were also tuberculous. He was sent away to the sea-side, where he was in due course apprenticed to a carpenter; from then till the present time he has had no signs of phthisis, but the glands have always remained somewhat enlarged, becoming larger whenever he suffered from a cold. Recently he had an attack of influenza, and noticed that the glands remained larger than usual. On examining the patient it was found that all the superficial lymphatic glands were considerably larger than they should be, but otherwise the boy appeared to be in perfect health. Mr. Beale remarked that in these cases it was not easy to lay down any definite rules of treatment; it seemed to him that in cases where there was a marked tuberculous family history it showed that the individual was not necessarily infected with tubercle from the time of his birth, but that he was suffering from a condition which resulted in the leucocytes of his blood being unable to destroy tubercle bacilli when they had infected any tissue or organ of his body, so that when exposed to a risk of tuberculous infection he became infected and the infection, moreover, spread, ultimately involving all his lymphatic glands. So long as he kept in good health nothing further appeared to happen, for directly the tubercle bacilli multiplied to an alarming extent in any particular place they were carried to the nearest lymphatic glands, where there were phagocytes sufficiently active to destroy most of them; but when the individual's health was in any way below par the phagocytes were not so active, and as a result the glands enlarged, the enlargement being at first inflammatory, caused by the bacilli or their toxins, or both, and subsequently passing on to caseation. In such cases it frequently happened that one or more of the glands underwent suppuration. Mr. Beale did not believe that this was due to tubercle. It meant that such gland or glands had received septic organisms, and being already tuberculous, the phagocytes in them were unable to cope with the septic infection. His view was that purely tuberculous glands never suppurated; they might get fairly large; they might caseate in the centre or in several places; they might even be converted into a mass of caseous material enclosed by the gland capsule, but they did not suppurate. The caseous material often became calcified and it was not uncommon to find the remains of such a lymphatic gland consisting of a capsule containing

simply a calcareous nodule. In a case like the one before him, what was the proper line of treatment? He thought it was as follows: (1) To make certain that the glands were tuberculous by removing one or its contents and examining in the clinical laboratory; (2) to examine the patient and find out if there were any lesions on skin or mucous membrane such as would be likely to allow of the entrance of septic organisms, and to treat them efficiently and tell the patient to avoid as far as he possibly could the formation of such lesions; one of the commonest was carious teeth, and if any existed they should be dealt with by the dental surgeon; (3) to take every precaution in the way of keeping up the patient's general health by obtaining plenty of fresh air, exposure to sun's rays, good feeding and tonics. If under these conditions one or more glands should unfortunately become infected with septic organisms and form one or more abscesses, the latter should be dealt with by incision and draining under strict antiseptis, when they would in nearly every case heal up satisfactorily. He said that in a few cases they did not heal up, but that the skin over them became undermined, a typical tuberculous ulcer resulting. Under good hygienic conditions and the application of mercury, such as *lotio nigra*, or *ung. hydrarg. ox. rubri dil.*, or an ointment containing iodoform, this would heal up, providing it were kept aseptic. If it was found that superficial lesions were continually recurring, for instance, eczema of the face, carious teeth, ulcers in the mouth, then the right thing to do was to remove the whole of the glands likely to be infected, carefully choosing a time when they were not suppurating. He laid stress upon the fact that every gland should be removed; it was often not possible to do this through one incision, in which case they should be removed in groups until all glands near the seat of infection had been extirpated. It was, of course, quite impossible to remove all the tuberculous glands all over the body, and he did not see the use of removing, say, all the tuberculous glands in the neck and leaving tuberculous glands in the axillæ and groins, but any group of glands which were likely to become septic as the result of a neighbouring skin lesion should be excised; he considered it bad practice to attempt to remove one or two which were septic, because as long as the risk of local septic infection existed so long would the tuberculous glands that remained be liable to form abscesses.

OPERATING THEATRES.

NORTH-WEST LONDON HOSPITAL.

HERNIOTOMY AND LAPAROTOMY—STRANGULATED HERNIA AND SECONDARY VOLVULUS OF THE SMALL INTESTINE.—Mr. JACKSON CLARKE operated on a man, *æt.* 61, who had been admitted for urgent symptoms of intestinal obstruction. The history of the case was as follows: The man had been at his work as assistant in a shop until four days previously; then he experienced a feeling of sickness which he attributed to a bilious attack such as he was subject to, and in consequence there was considerable delay in seeking medical aid. Towards the end of the second day, the symptoms having become more pronounced, a message was sent to the doctor requesting him to send a remedy for a bilious attack. The doctor, who was accustomed to treating such attacks in the patient, sent some medicine and said he would call next morning, when he found the patient was vomiting and slightly jaundiced. He examined the abdomen, where he discovered an irreducible inguinal hernia on each side of many years' standing; neither of these, however, presented any unusual feature, there being no tension appreciable to the touch or tenderness. An enema was administered which brought away some small scybalous masses. After this the patient seemed to improve, the vomiting becoming less urgent and the jaundice disappearing.

On the fourth day the vomiting still persisting, the doctor recommended the patient's immediate removal to the hospital, where he arrived late in the day. On examination the man, though weak, was not urgently distressed, the pulse was about 85 of somewhat high tension; his extremities, however, were cold, and it was evident that shock was beginning to be felt. The abdomen was especially prominent in front, the coils of bowel showing clearly upon it. Basing his opinion on the shape of the abdomen, Mr. Clarke expressed his conviction that the distension concerned only the small intestine, the sides and the upper part of the abdomen being less prominent than the front. The only other form of obstruction which in his experience produced so great an anterior protrusion of the belly was a volvulus of the sigmoid flexure, but in the latter case the prominence was usually even more pronounced than it was in obstruction of the small intestine, and the visible coils in the present case, from their position, direction and size, could only be coils of small intestine. No time was lost, but the patient was at once prepared for operation, which was begun twenty minutes after he reached the hospital. Seeing that there were two hernias, and after the long lapse of time since the commencement of the symptoms that there might be some abdominal complication, Mr. Clarke decided to open the abdomen in the middle line. This was done, and on examining the hernial orifices from the inside a loop of bowel was traced to that on the right side; that of the left consisted only of sac and fatty tissue outside it. The hernial sac on the right side was then opened from the outside as quickly as possible, the internal ring divided, and a loop of congested bowel having been freed from some adhesions

which bound it to the sac and its neck examined and found to be free from ulceration, the loop was returned to the abdominal cavity and the inguinal canal closed in the usual way. On examining the bowel from within the abdomen it was found that gas would not pass from the distended to the collapsed portion of the small intestine; this was seen to be due not to any persistence of constriction at the neck of the previously herniated bowel, but to a twist of the mesentery which had doubtless taken place by the distended coils of small intestine accommodating themselves to the abdominal space and in so doing twisting the mesentery on its own axis. In order to undo the twist it was necessary to turn the distended coils of bowel out of the abdominal cavity, where they were received in a towel wrung out with hot saline solution. The twist undone, gas began to pass into the previously collapsed bowel, and the intestines were rapidly returned to the abdominal cavity and the wound sewn up. During the operation the patient's shock had naturally been increased, and on being returned to bed he was given an injection of strychnine and a large hot saline enema was administered. Mr. Clarke said that the moral of the case was very obvious: the long delay on the part of the patient and his friends in seeking medical aid was responsible for the difficulties met with in the case; had the man been seen on the first day, a simple herniotomy would no doubt have relieved all his symptoms, but after the volvulus of the small intestine had supervened the herniotomy alone would have been quite useless. The patient's prospects, owing to the exhaustion of four days' intestinal obstruction followed by an operation that lasted three quarters of an hour were, he considered, far from hopeful.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD APRIL 27TH, 1906.

The President, Mr. CLUTTON, in the Chair.

DR. G. A. SUTHERLAND showed a case of (?) Von Recklinghausen's Disease in a male, *æt.* 5. Nothing in the family history save that his mother and maternal grandmother have spots of pigment on the body similar to those of patient.

At the age of six months a swelling the size of a bean was noticed on the right temple, and the right cheek and eye appeared to be growing out of proportion to those on the left side. All these swellings have greatly increased.

Special Features.—A swelling over the right frontal bone, firm and nodular. Right upper eyelid much hypertrophied and hanging over the eye. Right eye enlarged and apparently proptosed. Right cheek enlarged and contains nodular thickenings in its substance. Pigmentation is present over the frontal swelling, the right upper eyelid, the trunk, the axillæ, and the groins. Skiagrams show great enlargement of the orbit on the right side.

Negative Features.—No evidence of visceral disease, save a trace of albumen in the urine. No pain or tenderness, nor evidence of central nervous disease.

Mr. CLUTTON suggested the diagnosis of leontiasis ossea, in spite of the age.

Mr. W. G. SPENCER contrasted the condition with the reverse one of morphœa, and considered that it was a simple hypertrophy of trophic origin.

Mr. G. PERNET considered the case to be an anomalous one of Von Recklinghausen's disease. This sometimes went on to sarcoma formation, as in cases described by Rolleston and others.

DR. PARKES WEBER thought that the neuro-fibromata on the side of the head, together with the typical pigmentation stamped the case as being one of Von Recklinghausen's disease.

DR. SUTHERLAND commented on the limitation of the bony condition to the territory of the 5th nerve, and queried whether it was sarcomatous.

DR. F. PARKES WEBER showed a case of "Spontaneous" Fracture in the Tarsus in a woman with Argyll-Robertson pupils. The patient is a married woman, *æt.* 45. About twelve months ago the right foot became swollen and painful. On admission there was a great swelling of the right foot, especially of the dorsum, and crepitus could be felt. A skiagram showed that a portion of the head of the astragalus was broken off and displaced. There were Argyll-Robertson pupils on both sides. The knee-jerks were present. Under rest in bed there has been great improvement in the condition of the foot, but mercurial inunction had likewise been employed, followed by the internal use of iodide of potassium.

Mr. CLUTTON pointed out that the joint certainly had all the local features of a tabetic arthropathy.

DR. WEBER said Argyll-Robertson pupils meant old syphilis, though not necessarily tabes, and he considered whether the joint condition might be gummatous.

Mr. G. PERNET showed a case of Ringworm cured by the exposure of X-Rays. The boy, *æt.* 7, was first seen in October 1905, with a patch of ringworm occupying the greater part of the occiput. On October 19th, 1905, he had one exposure of the X-rays, according to the Sabouraud-Noiré method (platino-cyanide of barium pastille). This was followed by the falling out of the stumps and hairs on parts exposed, followed by growth. The results had been excellent, the hair having grown well. No disease could be now made out.

Mr. PERNET pointed out the advantage of the Sabouraud method over fractional X-ray treatment, and referred to the extensive benefits that the Paris schools had received from its application.

Mr. G. PERNET showed a case with Lymphangiectodes. The patient was a young woman, *æt.* 26. The disease had commenced at the age of five months. When first seen there were nine or ten groups of deep-seated vesicles occupying the right side of the chest from the neighbourhood of the posterior axillary fold downwards and forwards, but not reaching as far as the right nipple line. The lowest and largest group was situated on a deeper-seated mass (lymphangiectatic pachydermia of Rindfleisch), and some hæmorrhage had occurred into the vesicle-like lesions.

Mr. CAMPBELL WILLIAMS thought that the early stage of such conditions were to be seen frequently in surgical clinics as lymphatic nævi.

Mr. W. H. BATTLE showed a case of Post-Auricular Fistula. The patient, a girl, *æt.* 11, was admitted to St. Thomas's Hospital on April 19th, 1906. There was a minute opening in the fold behind the right ear, half an inch above the level of the lobule, which only admitted a small probe; from this there was an intermittent distillation of a clear fluid. There was no redness to indicate the orifice, which it was difficult to find when there was no flow of the fluid. The parotid gland was normal. The flow is not increased during meals, but is increased when an acid-drop is given. The opening was in a small, hardly perceptible, linear cicatrix. The fluid was of the nature of saliva. There was a history dating back to the time when she was a year old; at that time it is said that an abscess behind the ear was opened by a medical man, but no further particulars can be obtained.

Mr. W. H. BATTLE showed a patient after operation for perforation of a second Simple Ulcer of the Jejunum into the general peritoneal cavity.

K. C., a single woman, *æt.* 30, was admitted to St. Thomas's Hospital on March 14th, 1906, for symptoms which she herself diagnosed as due to "perforation."

There was some pain in the abdomen on the 12th, which she could not localise. At 9 a.m. on the morning of admission there was a sudden increase of pain, which was now in the upper part of the abdomen, and she vomited.

At 3 p.m. she was lying on her back, with eyes slightly sunken, but not at all anxious-looking.

The abdomen was moving fairly on respiration. It was tender, especially to the left of the umbilicus, and still more so near the lower end of the scar. In that region the muscular rigidity was most marked, and there was distinct swelling. The usual operation was performed.

She left the hospital on April 12th, having made a very satisfactory recovery.

Microscopical examination of the edge of the ulcer showed only an acute inflammation.

It is of interest to note that there were no adhesions found at this operation, also that there is now no hernial protrusion of any of the scars.

The previous history of this case was as follows: She was admitted in March, 1903, for perforated gastric ulcer. This ulcer was situated in the anterior aspect of the stomach, near the pylorus, and was surrounded by a good deal of thickening. It was sutured, the peritoneum cleansed, and a drainage-tube left in the lower wound. Anterior gastro-enterostomy was performed on April 9th, 1904, for pyloric stenosis.

On May 6th, 1905, she underwent operation for perforation of a simple ulcer of the jejunum; this had given into the general peritoneal cavity. It was a circular, clean-cut ulcer, situated about 1½ inches from the line of junction of the bowel with the stomach. The ulcer was sutured, the peritoneum cleansed, and the two wounds through which this was done closed without drainage.

Mr. W. G. SPENCER said that ulcers of the jejunum had been thought to be commoner after anterior gastro-enterostomy, but Mr. Patterson and others had disproved this.

Mr. W. H. BATTLE also showed a Deformity of the Ulna, with Dislocation of the Head of the Radius associated with Multiple Osteomata.

Dr. LEONARD GUTHRIE showed a case of Extreme Obesity with Precocious Puberty in a girl *æt.* 3. The child had always been rather plump, but had been rapidly growing fatter during the past six months. Height 2 ft. 9½ ins.; weight, 37½ lbs. She had grown an inch and increased 6 lbs. in weight in three months. The fat was fairly evenly distributed and also existed in pads or rolls round the neck and about the chest and flanks. The features looked small, and the temporal regions were masked owing to masses of fat in the cheeks.

Measurements.—Round neck, 12½ ins.; chest, 25½ ins.; abdomen, 26½ ins.; upper arm, 8 ins.; lower arm, 7½ ins.; thigh, 13½ ins.; calf, 8½ ins.

The breasts were beginning to develop and hair has appeared on the pubes during the last three months. There had been no discharge of blood as yet. *Assimilation* was poor and the heart-sounds were weak. The pulse was usually intermittent and irregular and averages 120–130 per minute.

Temperature was usually subnormal—97°–98°.

Urine was normal. Intelligence was good.

Dr. SUTHERLAND had seen this case six months ago, when there was only obesity. He contrasted the present condition with the commoner one of obesity, combined with mental deficiency.

Dr. PARKES WEBER said that probably the condition was due to a hypernephroma of the adrenals.

Mr. CLUTTON thought that most cases of precocious sexual development were male.

Dr. GUTHRIE referred to a collection of cases made by Drs. Bullock and Sequeira. Of the two males and twelve females with sexual precocity, all had obesity except six of the females. All had hypernephromata usually of a carcinomatous nature.

Dr. A. E. GARROD showed a case of Muscular Atrophy in a child (case for diagnosis). The patient was a girl, *æt.* 11, who exhibited somewhat extensive muscular atrophy, and a condition of the limbs of the left side which was said to date from a paralytic attack at the age of one year. There was some affection of the facial muscles—fibrillary twitching around the left angle of the mouth and a tendency for the right side of the mouth to be drawn down when the teeth are shown. In the attempt to whistle the right side of the mouth is not pursed up. The tongue is protruded straight. There is atrophy of the lower portions of both pectoral muscles and of the deltoids. The most extreme wasting is in the first dorsal interossei of both hands, which do not react at all either to the Faradic or galvanic current. None of the wasted muscles showed any reaction of degeneration. There was some scoliosis and deformity of the thorax. Babinski's sign was obtained on the left. The left triceps jerk was well maintained. The left arm was small, and its muscles were generally wasted. There was conspicuous atrophy of the thumb muscles and interossei—*main en griffe*. The forearm was held in a position of extreme supination, and could not be pronated. The left leg was an inch and a quarter shorter than the right, and there was *pes cavus*. The wasting was most pronounced in the muscles of the thigh.

Dr. FARQUHAR BUZZARD thought the most likely diagnosis was one of myopathy grafted on an old hemiplegia.

Dr. A. E. GARROD showed a case of Angio-Neurotic Edema. The patient was a girl, *æt.* 20. At the age of fourteen she began to have recurrent attacks of acute circumscribed œdema of the right cheek. The attacks recurred at quite irregular intervals. The patch of œdema was always in the same position, on the right cheek. In some of the more severe attacks

constitutional symptoms were present, such as shivering at the onset, and "pains all over." There have been no articular troubles. The patches were not the seat of any burning sensation or itching. Polyuria had been noticed to accompany the attacks. Three months ago a severe attack began in the usual situation, but the œdema extended to the nose, both eyelids, and the forehead. This attack also differed from all previous ones in the fact that, instead of subsiding in three days, the œdema has persisted up to the present time, and has not been influenced by treatment. The urine contained a cloud of albumen, but there is no œdema elsewhere than in the face.

Dr. PARKES WEBER considered that the continuance of the œdema and its limitation to one part were against Dr. Garrod's diagnosis.

Mr. W. G. SPENCER suggested a local lesion, such as a chronic streptococcal infection of nasal origin.

Dr. LEONARD GUTHRIE showed a case of Paralysis of Left Sixth and Paresis of Left Seventh Nerves. Patient was a girl, æt. 3. About six weeks ago she was noticed to squint and to turn her head to the right side. She began to limp and did not care to walk. On admission to Paddington Green Children's Hospital, April 19th, 1906, her condition was as follows: The head was almost constantly inclined towards the right shoulder, her eyes twisting in the same direction, downwards, and to the right. When she looked towards the left side there was marked internal strabismus of left eye, but the right moved normally inwards. The left external rectus was paralysed, but no other ocular muscle was affected. There was no optic neuritis. The whole of the left side of the face was parietic. Beneath the left zygoma there was a prominent swelling about the size of a five-shilling piece, slightly tender, ill defined and elastic, or indistinctly fluctuating on pressure. There was a tuberculous nodule on the back of the right hand, said to have existed for three to four months. The child was dull and apathetic, never spoke, cried in a half-hearted way if examined, or spontaneously, but did not seem to be in pain. Gait was slow, rather shuffling, and unsteady. Kneejerks were active. No ankle-clonus. *Diagnosis*.—Probably tuberculous disease of bone in malar region, involving left facial nerve externally and left sixth nerve internally. The deviation of the head was probably adopted to avoid diplopia.

Mr. W. G. SPENCER remarked that the position of the head might be due to a lesion of the eleventh nerve.

Dr. FARQUHAR BUZZARD thought the most probable diagnosis was a tuberculous mass in the left pontocerebello region.

Mr. BATTLE also showed a case of extensive Ulceration of the Mouth in a man of 38. The duration was eighteen months.

Mr. W. G. SPENCER thought the ulceration was of a tuberculous nature.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, APRIL 6TH, 1906.

SIR ARTHUR MACAN in the Chair.

Dr. J. S. ASHE exhibited a "new cystic ovary perforator and forceps."

Dr. HORNE showed a "myoma of the uterus showing cystic and calcareous degeneration." He said the patient was æt. 45, and the mother of six children, and had menstruated regularly. The tumour occupied the whole abdominal cavity. It resembled an ovarian tumour, as there was considerable feeling of softening about it. Notwithstanding the large size of the uterine cavity, the clinical history revealed no menorrhagia. A loud tympanitic note could be elicited in front of the abdomen. On removal of the

tumour he found it contained a large degenerative cystic cavity, with a number of small cysts and calcareous areas. The report of the pathologist (Professor McWeeney) showed that the organ was enormously enlarged owing to intra-mural fibroids, and in the centre is a cavity resembling a cyst. The microscope shows the tissue of the tumour to consist of unstriated muscle, and the cyst to be a "pseudocyst," i.e., one due to ischæmic necrosis of the muscle and its gradual softening. There are no genuine cysts in any of the sections, and no evidence of malignancy.

Dr. H. TWEEDY said he would like to know was a pedicle looked for through the rectum in this case? He did not believe that the size of the uterus was a necessary feature of distinction between ovarian cyst and myoma. Sub-peritoneal myomata were not likely to enlarge the uterus.

Dr. R. J. ROWLETTE said he had examined some specimens which simulated the appearances of the one shown.

Sir ARTHUR MACAN said he had come across a case in which a true fibro-cyst was manifest, the fluid of which coagulated on exposure. He did not know whether the pathology of this coagulable condition was thoroughly determined or not.

Dr. HORNE, in reply, said the patient after admission to hospital had a febrile attack, and had the facies of a person suffering from ovarian tumour. The muscles of the chest and forearms were wasted. The tumour and the cervix uteri were one body. He did not make a rectal examination for a pedicle, as the case admitted of no doubt, though he appreciated the value of that procedure in ovarian disease.

CANCER OF OVARIES.

Dr. HASTINGS TWEEDY exhibited a specimen of "cancer of both ovaries." He said the patient was a girl of twenty-one, who had been operated on in a City hospital some weeks previously for an ascitic collection, supposed to be the result of tuberculous peritonitis. She entered the Rotunda Hospital five weeks afterwards, in an apparently dying state, and enormously distended by peritoneal dropsy. On opening the abdomen, he found the intestines tucked up under the diaphragm and very adherent to each other; they, together with the entire peritoneum, were studded with coarsely granular masses, which he remarked at the time of the operation resembled endothelioma rather than tubercle. The ovaries appeared papillomatous, and were both removed. The abdominal cavity was drained with five wicks of iodoform gauze in the hope that they would be the means of causing an adhesive peritonitis, and so obliterating the weeping surfaces. For several days she poured fluid through the drains, but this gradually became less, and she left hospital symptomatically cured, and declaring that she was feeling better than she had done for two years. Dr. Rowlette, who examined the pathological condition of the parts removed, would be able to deal more fully with the microscopic findings.

Dr. R. J. ROWLETTE said the tumours were of a nodular character, the nodules varying from the size of peas to that of beans. In the substance of the nodules there were small cysts, some of these being filled with a clear, and others with a blood-stained, fluid. Both ovaries were similarly affected. Microscopic examination revealed masses of large cells, with a slight fibrous stroma. He regarded the tumour as an endothelioma, originating probably from the endothelium of the peritoneum.

Sir ARTHUR MACAN said he recalled a case in which, when the abdomen was opened, a large tumour thought to be malignant was apparent. On removing the tumour the patient got quite well; but the diagnosis of malignancy was possibly not correct. It was interesting to note how drainage, in the case under discussion, had the same beneficial effect as excision had on tubercle.

Dr. H. TWEEDY said he had examined the patient

that morning. Her abdomen was hard, and the cancer seemed again advancing.

HERNIA OF THE GRAVID UTERUS.

Dr. ARTHUR HOLMES read a paper on a "Case of Hernia of the Gravid Uterus" through an old abdominal scar. The patient had become pregnant shortly after the operation, and had noticed a lump protruding from the lower part of the abdomen. This after the confinement had almost disappeared. She again became pregnant, the lump steadily increasing, and circular ulcers formed where the clothes and thighs had rubbed. After delivery in November, 1903, the tumour remained, though smaller in size. On December, 22nd, 1905, she came to the Rotunda Hospital. On examination there was found a tumour springing from between the umbilicus and symphysis, which, falling forward, reached more than half-way down the front of the thigh. This proved to be the uterus, and the fetal movements were felt. The skin was very thin, and large circular ulcers were distributed over its surface. Some of these extended to the uterine muscle. The patient stated positively that she was at full term, and that labour pains were beginning. She delivered herself suddenly without any trouble of a live child, which presented all the appearance of being up to full term. Its weight was $3\frac{1}{2}$ lbs., and its length 14 inches. The placenta was removed manually on account of hæmorrhage. Reduction of the uterus was impossible on account of the adhesions. The diminutive size of the child was thought to be due to the diminished blood supply, consequent on the abnormal position of the uterus, and the constriction caused by the ring of the sac.

Dr. HORNE said he had never seen a case of this kind. It was hard to conceive how the child was born through so great a constriction.

Dr. A. HOLMES said the woman delivered herself, and had no pain. The tumour was about the size of a man's head. Dr. Purefoy told him that the woman is going about her work and is apparently well. The child died shortly afterwards of an attack of green diarrhoea.

Dr. J. S. ASHE read a paper entitled "Some Remarks on Uterine Suspension and Shortening Round Ligaments" which will be found in another column under the heading of "Original Papers," page 467.

In the discussion that followed, Dr. HORNE remarked that when the uterus was retroflexed after delivery, it rarely recovered its position; and it was a question whether it should be left alone severely unless some symptom demanded interference. He had rarely ever seen any untoward results follow the use of pessaries; and if such did occur, it was possible the pessaries had not been properly applied.

Dr. HASTINGS TWEEDY said it was not uncommon to observe retroflexions which did not give rise to symptoms. These were often congenital cases, and in such this backward position must be considered normal. It is almost unnecessary to state that these cases were best left untreated. Pessaries might well be compared to trusses; they had a narrow sphere of usefulness, but were by no means harmless. He did not think enough stress was laid on the mental ill-health likely to be engendered by the constant wearing of a pessary in the case of neurotic patients. He had personally seen nothing but good follow the fixation of the uterus by operative measures.

Sir ARTHUR MACAN said it was obvious there were no serious symptoms connected with retroflexion of the uterus, whether congenital or acquired, when a woman could go about in that condition for twenty years without knowing that anything was amiss. There was a theory that it brought the ovaries into Douglas' pouch. He rather favoured the use of pessaries. A woman came to him who had worn a pessary for eight years. She had no vaginitis, and the pessary showed no signs of wear. If pessary treatment was at all beneficial, it was preferable to operation.

Dr. ASHE briefly replied.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD APRIL 9TH, 1906.

Mr. BOWREMAN JESSETT, President, in the Chair.

Dr. MACNAUGHTON-JONES read the following notes on

THE USE OF VIOFORM.

At a meeting of the Society in February, 1904, I brought before its notice a case in which most unusual results followed the use of iodoform. It was a case in which I ventro-suspended the uterus and resected an ovary. Many years previously most severe consequences had followed in this same patient from the dressing of an ulcer in the leg with iodoform, viz., œdema of the limb, with an extensive slough. Of this I was in ignorance at the time of my operation. The preparation used by me was moist sterilised 10 per cent. iodoform gauze. Briefly, the results were extensive vesiculation of the skin of the abdomen, the occurrence of bullæ simulating those of pemphigus, extensive eczematous vesiculation on all the extremities, and a papillary eruption on other parts of the body, followed by free desquamation. The same patient was again brought under my notice recently for a large cyst of the same ovary that I had resected on the previous occasion. On operation, it was found that both ovaries were diseased, with attendant salpingitis. In the toilet of the patient I had forgotten the previous effects of the iodoform, or I should not have used any covering but plain sterilised gauze. The wound was, however, freely dusted with vioform, and finally dressed, before I remembered the patient's idiosyncrasy.

In February, 1905, I brought the use of vioform before the Society, having seen it first at Professor Fritsch's clinic at Bonn, drawing attention to its greater diffusibility, its capacity for sterilisation, and the odourless nature of the powder. Suffice it to say, that this patient's wound healed without the least trouble or irritation. The Michel's clips were removed on the fifth day, and the wound was dressed throughout with vioform. Dr. Macnaughton-Jones added that he had brought some of the powder, which was perfectly odourless. So far he had had perfect results with it.

Dr. EVERTSMANN (Bonn) remarked that the powder had been used in Professor Fritsch's clinic for three or four years now, and there never was any trouble with it. He thought it was a very fine powder for the abdomen because, being very dry, it absorbed the fluid well. It was an excellent powder for use in draining an abdominal cavity.

MYOMATA OF THE UTERUS.

Dr. A. E. GILES showed three specimens of myomata of the uterus and read notes of the cases, which will be found fully reported on page 466 of present issue.

Dr. FREDERICK EDGE brought before the Society three specimens:—

1. Strangulated myoma of the uterus simulating cancer of the fundus.
2. A pregnant uterus with almost sessile myoma; removed by supravaginal hysterectomy.
3. A myomatous uterus with expanded cervix, removed by abdominal hysterectomy.

Dr. EDGE then read a short communication on "Supravaginal and Panhysterectomy." (This paper, together with the cases, will be found on page 469.)

Dr. SMALLWOOD SAVAGE showed a large myomatous uterus which Professor Taylor had removed by supravaginal hysterectomy from a diabetic patient. The patient was 46, married, and was enormous in size. She had had one child nine years ago, and one miscarriage eight years ago; she was regular, but complained of menorrhagia, the last period being three weeks before. Diabetes had been noticed for over a year, and there had been a rapid enlargement of the abdomen for several months. The urine was acid in reaction, 1038 specific gravity and contained much sugar and some albumin. As Professor Taylor

could find no statistics of hysterectomy occurring in patients the subjects of diabetes, he thought that the publication of this case might lead other operators to relate similar ones, so that the relative dangers to life might be recorded where the tumour had been left alone on the one hand, and on the other where, owing to serious symptoms arising from the growth, it would be thought advisable to remove it.

Dr. HEYWOOD SMITH wished to see a sagittal section of the specimen of cervical myoma as it did not show the site of origin at present. He inquired as to the method of suturing adopted in the case where myomectomy had been performed.

Mr. RYALL asked how Dr. Giles made the incision in the case of hysterectomy, whether vertically or transversely. He (Mr. Ryall) considered that a transverse incision would give rise to more hæmorrhage. He should like to know the after history of these cases. With reference to the two cases of hysterectomy, he did not think there was sufficient evidence in favour of panhysterectomy rather than supravaginal amputation. With regard to the other case in which peritonitis occurred, that peritonitis might have been due to, possibly, some septic material in the cervical canal, and less probably to anything produced at the time of the operation. If the operation was a clean one, there ought to be no reason for sepsis. Professor Taylor's case was an interesting one, and he admired the courage which prompted him to remove such a large tumour from a patient suffering from diabetes. He performed hysterectomy on a patient suffering from diabetes five or six years ago. She was suffering from pressure symptoms, and he operated. From a surgical point of view two great risks were run in operating on patients with diabetes, one being shock and the other sepsis. In his case the patient died from shock.

In regard to Dr. Edge's specimens, Dr. MACNAUGHTON-JONES said that the most important question connected with the hysterectomy in the case of the pedunculated myoma complicating pregnancy was the justification for the interference. The rule almost universally followed in such cases was not to interfere unless the symptoms absolutely demanded operation, and with certain rare exceptions this rule was also applicable to other forms of myoma complicating pregnancy. He had operated on almost a similar case to that brought forward by Dr. Edge. The patient had two attacks of peritonitis, and was suffering from pain, with considerable distress; the patient recovered, but the death of the ovum compelled him to empty the uterus. As regards his remarks on supravaginal hysterectomy, it was generally accepted that in malignant and septic conditions, cervical myomata, myoma complicated by adnexal tumours, pyo-salpinx, and with tumours in the broad ligament, the supravaginal operation was contra-indicated. If it were a thoroughly aseptic operation, he did not consider that there was any necessity to drain. With regard to Dr. Giles' case, of myoma removed by myomectomy, he did not think that there was anything particularly novel as regards the method of operation. He had seen some years since Zweifel remove a large tumour the same size as that shown by Dr. Giles in the same manner. The tumour was shelled out through the anterior incision in the uterine wall. Professor Fritsch, of Bonn, operated in many of these cases by morcellation. He had seen him removing several very large myomata in this manner. In doing so he did not divide the cervical wall. His dexterity in operating by this method was great, and it was surprising to see the rapidity with which the operation was completed, and the comparatively small amount of blood lost.

Dr. HODGSON considered the mortality in the removal of the uterus was principally due to hæmorrhage and sepsis. He should like to know whether the case of diabetes had temporary or permanent glycosuria.

Dr. SLIMON congratulated Dr. Giles on the success of his case of cervix myoma in which he had assisted. The operation was not a very simple one, but occupied a considerable time to carry out. The lady vomited only once, her temperature was normal, and she left the home on the fifteenth day perfectly well.

Dr. EVERSTMANN said he did not remember Dr. Fritsch to have lost a case of intra-uterine myoma. He did not see why in these cases there was any great danger. In the operation they did not open the peritoneum, but only brought the tumour out of the inside of the uterus. Then they could drain with gauze. If there was any fever douching removed it.

Dr. OLIVER remarked that about six months ago he removed, without any trouble a tumour by morcellation, which reached the umbilicus. He had previously done five or six similar operations.

The PRESIDENT said he thought that, as a rule, there was certainly no objection to drain through the cervix in cases in which sub-peritoneal hysterectomy was performed. There was very often some oozing going on in the stump, and if there was a drain through the cervical canal it would remove what might cause trouble afterwards. In such cases the septic mischief might arise from the vagina and therefore, he thought that the vagina should be disinfected before the operation commenced.

Dr. GILES, in reply to the criticisms on his specimens, remarked that, in the second case, the myoma occupied the anterior wall of the uterus. This was not really a matter of any difficulty because, supposing the tumour were simply in the anterior wall of the uterus, by making an incision over it the capsule was exposed, and the tumour could be removed. Of course if the tumour projected a great deal into the uterine cavity then in all probability the uterine cavity would have to be opened in any case. He used mattress sutures in closing the uterine wall after myomectomy. In the case of hysterectomy the incision through the uterus was vertical. Of course, a transverse incision would probably give rise to a great deal of hæmorrhage, but in making a vertical incision in the median line of the uterus there was practically no hæmorrhage at all. He had done altogether twenty-four myomectomies and exactly a hundred hysterectomies. He had not known any of his cases of myomectomy return with another growth. Unless the tumour was obviously solitary, or unless there were only one or two he should never do myomectomy; it was a risky thing to do with multiple myomata. With regard to the question of enucleation *versus* morcellation, he fancied that these things were partly a matter of training. He had operated by morcellation in several cases. In one case he removed a tumour about the size of a full term foetal head, but that was a case in which he was forced to do it. The tumour was partly outside the uterus, in the vagina. He went on knocking off chips of it until he eventually found he was inside the uterus right up to the umbilicus. If one could do a simple abdominal myomectomy or a hysterectomy, it struck one as a cleaner and more surgical operation than doing it by morcellation. The question of morcellation and enucleation was a large one, but if one commenced with morcellation there might be multiple fibroids which would afterwards also have to be removed in the same way, and this might be a very troublesome and lengthy procedure.

Dr. EDGE, in the course of his reply, said it was his custom in cases of sessile or pedunculated myomata to make flaps. But in the case he had shown that night the peduncle tempted him to ligature it. He tried to check the bleeding, but considering that he had cut into the venous sinuses in the uterine wall he did not think it was safe to leave the uterus, and therefore he removed it, especially as the patient had expressly desired him to do so. With regard to the ovarian pedicle he generally tied it, transfixing the broad ligament, and took as little tissue as possible. He tied it with stout silk (No. 5). He took up the arteries and tied them separately. The question of

drainage after operations of supravaginal hysterectomy was, he thought, a case of personal opinion. He would drain practically every case. Of course, if one had a myoma with a long cervix like an ovarian pedicle which could be absolutely correctly sutured, no doubt he would be tempted to go on with the supravaginal. Because he had published two deaths, he did not want them to think that all his supravaginal hysterectomies died. They did not all die by any means. At the same time, he felt that if he had done a pan-hysterectomy in those cases they would have stood a better chance. But if the surgeon were convinced that he had done such things as would probably lead to abortion, and if the patient had strongly expressed a desire to have the uterus removed if it were pregnant, he thought he was justified in leaving the uterus. Disinfection of the vagina was carried out in both cases, but he thought that the danger lay in the impossibility of disinfecting the cervix. In many of those cases the infection was in the cervical canal, and although every care might be taken in covering the canal, he thought the safer method was to have free and efficient drainage just as they should in any operation outside the abdomen. As to morcellation, Professor Taylor and himself had removed a good many fibroids by that method, and he had seen it done in Germany and Paris. But the fact that they had ceased to do it was strong proof that they had found grave reasons against it. In the first place, the loss of blood in these cases was exhausting. Professor Fritsch was perhaps more of an adept at it, but he (Dr. Edge) had seen that method result in far greater loss of blood than hysterectomy. Again, the shock in long-continued operations of the kind was very great. Further, the injuries done were uncertain, and that, he thought, was one of the strongest reasons against morcellation. Lastly, one was not sure that there were not other myomata.

Dr. MACNAUGHTON-JONES read notes on a specimen of malignant adenoma of the ovary. This, with a case shown by the PRESIDENT, of sarcoma of the left ovary, we hope to publish in our next.

LIVERPOOL MEDICAL INSTITUTION

MEETING HELD THURSDAY, APRIL 19TH, 1906.

FRANK T. PAUL, F.R.C.S., President, in the Chair.
SCABIES.

Dr. F. H. BARENDT read a note on "Scabies," emphasising certain points in diagnosis, mode of infection and treatment. In cases where the primary eruption was incapable of detection—cuniculi not being recognisable—but the sites of the secondary eruption due to the pruritus were well defined, the patient should be treated for scabies. The nipple area in women and the genital region in man, should always be carefully examined especially where the eruption between the fingers, in the case of cleanly individuals, was absent. Dr. Barendt drew attention to the method of distribution which thus accounted for the universality of the lesions in long-standing scabies. He considered that infection was almost always nocturnal, and the result of prolonged contact with an infected person, and that the handling of bed or body clothes or shaking hands with a scabetic, could communicate scabies was, to say the least, not proven. In ascertaining the source of infection it was necessary to question the patient upon his surroundings of the three weeks previous to the onset of itching. Dr. Barendt used the B-naphthol ointment first introduced by Kaposi. It was a superfatted, soft soap containing about 9 per cent. of B-naphthol. It had the advantage of neither staining nor possessing a disagreeable odour, and, above all, did not aggravate the secondary lesions, which sulphur ointment, especially in long-standing scabies, was apt to do.

Dr. G. STOPFORD TAYLOR stated that the treatment was unsatisfactory unless all underclothes and bed-linen were boiled, and those clothes which could not

be so treated were stoved. The Liverpool sanitary authorities would undertake the stoving free of charge.

Mr. COLIN CAMPBELL showed a patient after twelve weeks' treatment by intra-tracheal injections of izaral.

A CLINICAL ANALYSIS OF TWENTY-TWO CASES OF INTRATHORACIC TUMOUR.

Dr. T. R. GLYNN classified twenty-one cases of intrathoracic tumour under the following heads:—Hodgkin's disease, with implication of the mediastinal glands, four cases; sarcoma of some groups of superficial glands, with implication of the mediastinal glands, four cases; primary sarcoma or cancer of the mediastinal glands or thymus, six cases; primary cancer of the lungs, six cases; sarcoma of the pleura, one case. The complications included pleuritic effusion in six cases, in two of which it was hæmorrhagic; invasion of the vertebral canal by growth in six cases, causing paraplegia of sudden onset in four and of gradual onset in two cases. The secondary changes in the lungs were illustrated by drawings; the earlier symptoms in these cases were pain and cough, the later—cancer of the lung (three cases)—sanguineous expectoration. Physical signs of intrathoracic pressure were present in thirteen cases. The remaining physical signs and the duration of life were discussed, and a short account of the individual cases given.

TREATMENT BY HYPNOTIC SUGGESTION.

Dr. A. BETTS TAPLIN said that hypnotism had been evolved in the past from such a labyrinth of superstition and nonsense that he almost felt inclined to apologise for introducing the subject to the notice of a professional audience, as an acknowledged branch of therapeutics. Its history during the last 170 years was full of absorbing, even of tragic, interest here and there, and was ably told in the works of many medical men, both in England and on the Continent. Hypnotism was generally acknowledged by all observers to be a physiological and not a pathological condition, and to be absolutely free from danger in competent hands. It had been found most useful in those many cases which were the despair of the profession, and which were characterised by pain, spasm, or other nervous phenomena, in which no organic cause could be found, and for which no other therapeutic measures seemed to be of any avail. The time for its study and reception by the medical profession was ripe, and to prevent its possible abuse in ignorant or unscrupulous hands, it was much to be desired that, as soon as possible, its use should be limited by legal enactment by properly qualified persons under proper control.

Dr. K. GROSSMANN thought that no advance had been made in our knowledge of the subject for twenty years. The account he had given before the Medical Institution sixteen years ago was based on a visit to Professor Charcot at the Salpêtrière, and a stay at Nancy, where he studied the methods and saw the patients of Dr. Liébault and Prof. Bernheim. Prof. Charcot's patients were all hysterical, while at Nancy every sort of patient was treated; three phases were distinguished—lethargy, catalepsy and somnambulism. The Nancy school recognised nine different degrees of susceptibility, ending with somnambulism followed by amnesia. All the phenomena were explained by suggestion, and the mode of producing the various stages of hypnosis employed by the Paris school were recognised as suggestions. The Nancy school considered the hypnotic state as analogous to sleep, with the difference that the subject was *en rapport* with the operator, hearing and understanding him. Dr. Grossmann had no difficulty in hypnotising subjects, but he had never seen any therapeutic results in his cases—paralyses of ocular muscles, restricted fields of vision, &c., nor had he himself seen the extraordinary trophic phenomena, blisters and burns, so graphically described by Prof. Krafft-Ebing. It was always a difficult matter to find out how far the subject was really under the influence of the operator and to what extent he was shamming. For his own part, he thought Braid's motto, "Unlimited scepticism is equally the child of imbecility as implicit credulity," was all very well,

but the following one was safer—"When you see a fact, doubt it."

Dr. A. E. DAVIS agreed that subjects often deceived the hypnotiser, but could not accept the statement made by one of the speakers that hypnosis was produced in hysterical neurotic soil, which, in his experience, was the least fruitful of all. He agreed with the theory of the late F. W. Myers that the phenomena were produced in the subliminal consciousness, and which was supported by the fact that the acuity of the senses could be enormously increased. He pointed out that the thirteen patients mentioned by Dr. Taplin, two only were males. The objection of males to trying hypnosis was a great drawback to its practice and study. Though he believed it was not possible to instil viciousness into a subject who had no natural inclination to it, the dangers of being *en rapport* with some women subjects were obvious. He had repeatedly produced trophic changes. Convulsions, in hysterical subjects could be obviated by self-confidence and knowledge on the part of the hypnotiser.

Dr. S. WHITAKER said that a better description of the treatment would be "treatment by suggestion, with or without hypnosis," for it was usually unnecessary to hypnotise the patient more deeply than the lightest lethargic stage when he would accept suggestions, and the operator could obtain good therapeutic results." During treatment there should be no distressing sounds and sights. He used the method of "monotony." The cases suitable for this treatment were those in which there were functional disturbance, including most cases of organic lesion, and so far as this element existed it was possible to benefit the patient. He had obtained excellent results in the attacks of palpitation of exophthalmic goitre, headache, insomnia and pain generally. Owing to the depth of hypnosis acquired to produce anaesthesia, the method was not likely to compete with ordinary anaesthetics.

Dr. C. T. STREET said probably all were agreed that there was such a thing as hypnotism, but were divided as to its usefulness. He asked, was not treatment by suggestion without hypnosis preferable? Those who worked among the insane knew what beneficial results could be produced by suggestion; how the melancholic was encouraged to look on the brighter side of things; how the maniac was calmed by suggestion and example, and how it could be suggested to the hysterical that she could exercise self-control if she tried. The result from this form of treatment might be slow, but it was certainly more sure and lasting than that produced by hypnosis.

Drs. T. S. Glynn, Stanley Gill and T. B. Warrington also took part in the discussion.

CORK MEDICAL AND SURGICAL SOCIETY.

GENERAL MEETING HELD WEDNESDAY, APRIL 11TH, 1906.

The President, Dr. R. P. CROSBIE, in the Chair.

Dr. COTTER read notes of a case of Ectopic Gestation which will be found on page 470, under "Clinical Records."

Dr. Cotter also read notes of a case with obscure abdominal symptoms. A man, D. T., *æt.* 20 years, after a few days of malaise, got an acute pain in the belly, with vomiting and great collapse. There was tenderness, and some rigidity over the right iliac fossa. Thinking the appendix implicated, he opened the abdomen, and beyond some serous effusion, found nothing abnormal. He removed the appendix, which was healthy; patient sank and died the next day. *Post mortem*: The pancreas was found greatly enlarged, and somewhat bile-stained, with a peculiar "marbled" marking of its surface. Dr. Moore found no evidence of inflammation or degeneration. Dr. Cotter remarked that he was at a loss to know the

cause of death. Dr. Moore's report negated the diagnosis of acute pancreatitis, as also did the absence of fat necrosis. On the other hand, there was cyanosis of the skin of the face and belly, and localised tumescence of the upper half of the abdomen.

Dr. H. R. TOWNSEND read notes of a case of acute appendicitis in a girl *æt.* 10. He saw her the day after onset of symptoms. There were severe paroxysms of pain, referred at first to umbilicus, later to McBurney's point. He found a deeply congested appendix, which he removed. Dr. Moore examined the viscus, and found unmistakable evidence of early pus formation.

Dr. TOWNSEND said the case illustrated the necessity for instant operation in acute cases.

Dr. COTTER thought that the only exception to this rule was in cases known to be of the relapsing variety.

CENTRAL BOARD OF MIDWIVES.

MEETING HELD APRIL 26TH, 1906.

The President, Dr. CHAMPNEYS, in the Chair.

AFTER several minor matters had been settled, the Secretary read a letter from a certified midwife complaining of the increased fees charged by doctors when called in to a case attended by a midwife.

Mr. WARD COUSINS said this matter of fees was a serious one and ought to be thoroughly discussed. It was a fact that medical men did demand fees from midwives, and the members of the Board ought to express an opinion. There were cases where a fee was asked before a doctor would assist in an emergency. It did not seem to be understood that they expected to be paid. Of course, if the patient could pay that obviated the difficulty, but they could not always do so, and the matter ought to be brought under the notice of the Local Supervising Authorities.

The SECRETARY remarked that doctors often said to patients: If you employ a midwife, and then send for me, the fee will be two guineas; but if I take the case it will be only one.

Mr. WARD COUSINS added that Cardiff and Liverpool had made definite arrangements, and there ought not to be such hesitancy to settle a question so critical to the medical profession.

The CHAIRMAN reminded the speaker that the Privy Council would not help them. They had answered it was a matter of local legislation.

Miss WILSON asked how Cardiff and Liverpool had arranged.

The SECRETARY answered that counties submissive to the Local Government Board and boroughs were on a very different footing. The Borough Council could report what it liked and the County Council could not. The chief complaints came from country districts where the doctor was perhaps called up in the middle of the night to make a long journey, and no fee was forthcoming.

Dr. PARKER YOUNG added that doctors could not be expected to do this, and were justified in making sure of their fee beforehand, though such necessity was often hard on the patient, the midwife, and considerably hindered the proper working of the Act, therefore something definite would help every side. As there was now a new Government, he proposed sending in again all the former requests and pointing out the inefficiency of the present arrangements. There were still untrained midwives practising and a labourer earning, say, fifteen shillings a week, could not pay the doctor, and certainly would not want a certified midwife if he knew she was likely to burden him with a fee for extra help.

Mr. WARD COUSINS proposed, and Dr. PARKER YOUNG seconded a motion to hold a special meeting on the subject shortly.

The question of extra fees for examiners' travelling expenses was again discussed, and the secretary was instructed to calculate the average duration of the journeys undertaken by provincial examiners.

The Standing Committee having arranged at its last meeting that Shoreditch Infirmary might be

recognised conditionally on furnishing a syllabus satisfactory to the Board.

Mr. WARD COUSINS asked if a proper inspection had been made. Where were the maternity wards? He had heard that women were kept in the general wards until labour had commenced. The former wards might be next the fever wards for aught they knew. Those for maternity ought to be isolated. Hospitals were starting up all over the country with such wards for teaching purposes. Were the Board allowed to inspect and criticise?

The CHAIRMAN said the Board was not responsible. They could not sit in judgment on structural defects, and only two hospitals in London had isolated maternity wards. Shoreditch had only had one case of puerperal fever in five years out of 100 lying-in yearly.

Dr. PARKER YOUNG said it was evident Mr. Ward Cousins did not respect the rate-payers. The Government allowed the Board to pass women who could neither read nor write, and it would not do to entertain such a very high ideal yet for infirmaries.

It was agreed to consider this question again, and the proceedings then came to an end.

FRANCE.

Paris, April 30th, 1906.

SYMPTOMATIC TREATMENT OF STITCH IN THE SIDE.

CHARACTERISED by sharp pain coming on rapidly and even brusquely, situated on one of the sides of the thorax in a point generally well defined, increased by deep respiratory efforts and by the cough, stitch in the side is one of the symptoms most frequently observed and one of those for which the patient solicits the active intervention of the physician. Almost always the pain is the manifestation of divers lesions and is produced by very different causes: *Skin*: No special pain, only painful zones. *Muscles*: Pleurodyna. *Bones*: Fractures of ribs, costal caries. *Intercostal Nerves*: Intercostal neuralgia, mastodynia, cough, pulmonary tuberculosis, traumatic neuritis. *Phrenic nerve*: Phrenic neuralgia, diaphragmatic pleurisy, subphrenic peritonitis, pericarditis.

Intra-thoracic Organs: Pleura: Dry pleurisy, pleurisy with effusion, pneumo-thorax. Lung: Pneumonia, gangrene. Pericardium: Aorta, heart.

Abdominal Organs.—Fixed or flying pains provoked by an hepatic lesion (cardiac liver, perihepatitis). This complex ætiology indicates that the rational and efficacious treatment of stitch in the side is above all that of the cause.

Externally.—No time should be lost by applications of such anodynes as belladonna, hyoscyamus, opium, etc., while a blister will be proscribed. Revulsion: Tincture of iodine, generally inefficacious, warm poultices, mustard leaves, applications loco dolenti of a few drops of spirits of chloroform, thermo cautery, chloride of ethyl spray. Dry cupping, wet cupping (pleurisy and pneumonia).

Internally:—

Pyramidon, vi. gr.;
Carbonate of lime, iv.;
Veronal, iv.;
Diodine, †;

For one wafer, 2 to 3 a day. In rebellious cases, injections of morphia.

INTERNAL TREATMENT OF APPENDICITIS.

The medical treatment of appendicitis is, as every one knows, very important, frequently rendering surgical intervention unnecessary.

A confrere of no mean reputation goes so far even as to insist that this fashionable affection is always amenable to medical treatment. Exaggeration apart, nearly every practitioner has had amongst his patients very successful cases which encouraged him not to abandon the patient to the knife until he has exhausted the means at his disposal. The confrere in question

affirms that out of 80 cases he only lost two patients, and these were lost from the very beginning where no operation could have been successful.

His treatment, which is worth a trial, consists in warm poultices to the region and the administration *intus et extra* of collargol, according to the method of Cr  d  .

Collargol, 15 grs.;
Water, 7 oz.

A teaspoonful every hour.

If the general condition of the patient is grave, vomiting, tympanitis, he increases the collargol to 30 grs., and two teaspoonfuls should be taken every hour. Externally and twice a day, a half a drachm of the following ointment is rubbed in for 25 or 30 minutes into the folds of the elbow and thigh.

Collargol, 4 drachms;
Lanoline, 1½ oz.;
Axunge, 1½ oz.

If vomiting prevents giving the mixture by the mouth, it may be administered in enema but in larger doses.

GERMANY.

Berlin, April 29th, 1906.

THE TREATMENT OF PULMONARY TUBERCULOSIS BY MARMOREK'S SERUM.

THIS subject has lately been discussed by Prof. Stadelmann and his assistant Dr. Arnold Benfy, their opinion being very unfavourable. They write to the following effect:—Since Marmorek made his first communication on his antituberculous serum in November, 1903, at a Session of the Academy of Medicine in Paris, numerous publications have appeared in various countries, some for and some against the usefulness of the serum. A discussion arose in the last International Tuberculosis Congress in Paris on the subject, and whilst the communications on the remedy were rather coldly received, some speakers in the Congress expressed themselves very favourably as to the results obtained. From the observations made on it in our own department, we cannot agree with these favourable judgments. We do not disguise from ourselves the fact that the number of cases observed is too small to allow a final judgment to be formed; but in the meantime our experiences were so unfavourable that in the interests of our patients we felt ourselves obliged to discontinue further investigation in the matter. The serum has been employed by us in five cases of pulmonary tuberculosis in all three stages of the disease. No improvement in the objective condition was observed in any case, but on the contrary there was almost without exception a deterioration that compelled a discontinuance of the treatment. As regarded temperature, no fall in a moderate temperature was ever seen, but on the contrary the temperature rose under the injections. In non-febrile cases the temperature was repeatedly raised by the injections; a fall took place when the treatment was omitted, a rise again taking place on resumption of treatment. Rises of temperature up to 39° C. were observed. In some cases the temperature fell immediately after leaving off the treatment; in others again it persisted for as much as six to eight days. One patient after each injection had a remitting fever of a hectic character that disappeared when the injections were left off. It was certain that the injections of serum had as consequences rises of temperature, the character and duration of which varied very much. Further, in most of the cases, although the injections were made with the greatest caution, there were very irritable eruptions of uric acid, redness and painful infiltrations, and in some cases even slight cutaneous hæmorrhages around the point of injection. Painful glandular swellings followed the skin trouble several times. No suppuration took place, and the urticaria wheals disappeared in the course of a few days, but they were the source of a good deal of trouble to the patient. These cutaneous and glandular troubles must be

looked upon as toxic symptoms, which by their frequency seriously complicated the injection treatment. In no case was there any subjective or objective improvement after the injections. In one case there was even giddiness associated with nausea after the injections. The chest symptoms, cough, expectoration, night sweats, &c., remained unchanged. On the other hand, the general condition was influenced unfavourably, so that patients several times objected to the repetition of the injections.

Geh. Med. Rat. Dr. A. Hoffa relates his impressions of the treatment as regards tubercle of the bones and joints, and these are much more favourable than those of Prof. Stadelmann. He employed the treatment in about 40 cases of tuberculosis of the bones and joints, in some cases the injections being repeated for months. No unfavourable symptoms were set up by the treatment. Serious advanced destructive processes were not arrested, although he observed unusually rapid cicatrization on recovery in extensive osteomyelitis processes that could only be put to the credit of the serum. In many cases the serum had a decidedly good effect on the temperature, the general conditions, and the local disease. Already in the first series of 10 cases the good effect of the serum was observed in the resorption and retrocession of abscesses that recovered more rapidly than by other measures. More or less strong local reaction was observed in about one-third of his cases, but in no case was there any permanent damage. The condition of local irritation at the point of injection had generally disappeared within twenty-four hours. These irritations caused the course of treatment to be interrupted, but the difficulty was got over by giving the serum as a rectal enema. This method of administration he had now employed for six months, with the result that no local or general serum reaction had been met with since. The simple small enema was always retained and well borne. This method of administration had the advantage that it could be kept up daily for weeks and without losing its effects. The best marked of his observation of recovery of extensive superficial tuberculous disease was in a case that was treated by rectal medication.

It did not appear to the writer that the time had yet arrived for the formation of a definite judgment on the matter, but he thought this apparently valuable method of treatment of tuberculous diseases deserved more attention than it had hitherto excited.

AUSTRIA.

Vienna, April 29th, 1906.

GIGANTISMUS INFANTILIS.

Redlich presented a giant to the Gesellschaft, *æt.* 31, and measuring 71.9 inches or approximately 6 feet. According to his history he had suffered twenty-one years from lung affections, which probably account for the increase in stature. Notwithstanding this great length none of the secretory or genital organs were developed. Sexual activity was quite abrogated. The arms, hands, and legs were very long; the feet plump; scoliosis, cranium moderately large, but no signs of acromegalia. The epiphyses were not ossified; no hair on the face, which was wrinkled and lined, giving him a senile appearance.

The pelvis was not enlarged; the genitals very infantile, small, soft, and only a few rudimentary hairs on the pubis, with a right-sided inguinal hernia. The larynx was high, giving a boyish sound to the voice, while imbecility was present.

At the present time there is difficulty in the classification of these, as few giants are rarely normal in all the vegetative characters and are therefore characterised as pathological giants to distinguish them from the normal.

It may be noted that this case approaches perilously near acromegalia, but the infantile genitals, absence of the secondary function, non-union of the epiphyses compelled Brissand, Lannois, etc., to place them under a separate head as "Gigantismus Infantilis."

Redlich related the history of another, case that came

under his notice some time ago. His length was 185 centimetres with infantile genitals and no secondary sexual characteristics. In this case, however, progressive paralysis intervened, which finally brought about the exitus. This hypoplasia of the genitals may be accepted as peculiar to giant growth, as eunuchs are noted for extension of bone after castration, especially a lengthening of the lower extremities, with the same opening at the epiphysis as in infantile conditions. It is peculiar to note here also that dwarfs have a similar condition known, as nanismus infantilis, where the epiphyses are open and the genitals atrophied. We might therefore conclude that the absence of internal secretion reduced the development of the organ, while it increased the length of the long bones in gigantism infantilis, but acts as an inhibitory nanismus infantilis. The relation of acromegalia seems to be closely allied to the above, as not infrequently the hypophyses begin to increase and end in an enormous enlargement of the bony structure. It would seem that a new stimulus is originated at a later period, which causes more ossification, while the infantile state is only inhibitory.

PITYRIASIS LICHENOIDES CHRONICA.

Neumann showed a patient with small elevated efflorescent patches on the body of a circumscript character covered with scurf on a red base. Neumann said this was a rare affection, which he first described twelve years ago. It is closely related to papular syphilides and psoriasis, which led Brocq to designate it parapsoriasis.

FROM OUR SPECIAL CORRESPONDENTS AT HOME. SCOTLAND.

UNIVERSITY OF EDINBURGH.—REFORMS IN THE MEDICAL CURRICULUM.—At the forthcoming statutory half-yearly meeting of the General Council of the University there will fall to be considered a very important report of the Business Committee, containing, among other matters of university interest, the result of the committee's deliberations on a draft ordinance by the University Court changing the regulations for degrees in medicine. Four years ago the General Council requested the University Court to consider the feasibility of re-organising the medical curriculum on the lines suggested by the Pathological Club of Edinburgh, and in consequence a joint committee of the Council and Court drew up a memorandum suggesting reforms of the matters complained of. The present draft ordinance embodies the result of the deliberations on this memorandum by the Court, the Senatus, and the Medical Faculty. In 1902 the Council formulated the alterations required as (1) division of the academic year into three terms instead of two as at present; (2) the holding of all professional examinations thrice a year; (3) no student who has failed to pass an examination to be permitted to attend the succeeding classes of the course until he has been successful; (4) a prescribed order of classes, arranged in rational sequence must be followed; (5) a timetable so adjusted as to get lectures and hospital teaching over by lunch-time, and leave the afternoon free for practical work. To a large extent these alterations, so far as legislation is required to carry them into effect, are embodied in the proposed ordinance, the general idea of the scheme being that students should be allowed more freely than hitherto to pass the first three professional examinations by instalments, so that having been instructed in a particular subject they may be forthwith examined in it, and thus enabled to concentrate attention on subjects in which they are immediately undergoing tuition without being distracted by examination requirements on subjects previously studied. Under the new scheme a medical student beginning his curriculum in summer might pass his examinations in the following order and at the end of the following periods:—

First Division.—First Summer: Botany and Zoology

or Physics; First Christmas: Physics or Zoology; First Winter: Chemistry.

Second Division.—Second Winter: Physiology; Third Christmas: Anatomy.

Third Division.—Third Winter: Practical Pharmacy; Fourth Summer: Pathology; Fourth Winter: Therapeutics.

Final Division.—Fifth Summer: Forensic Medicine and Public Health; Fifth Christmas: Midwifery; Fifth Winter: Medicine and Surgery; Sixth Summer: Clinical Medicine, Surgery, and Gynaecology.

As compared with the present system the principal changes (in addition to the splitting up of the individual examinations by allowing students to pass them by instalments) are the lightening of the second professional by the transference of *materia medica* and therapeutics to the third, while this subject is again so divided that the "druggists" and elementary parts—recognition of drugs, practical pharmacy, &c.—are got over early, therapeutics being postponed until some experience has been gained in clinical medicine. Apparently the ordinance practically concedes a three term session and by implication another of the demands supported by the General Council for a system of three examinations a-year. The ordinance also empowers the Faculty of Medicine to prescribe the studies of a student who has been rejected before he is again allowed to sit for examination, and it is suggested that they should also be able to restrain him from entering upon new subjects. As the Business Committee characterise it, the ordinance is a "large and large-hearted measure of reform," and all interested in the Medical School of Edinburgh will join with them in hoping that it may soon become law. Like all other reforms, this one has to a great extent been thrust on the University from without, as the committee's report states it arose in the Edinburgh Pathological Club, and it is no secret that Professor R. J. A. Berry, now of Melbourne University, was the initiator of the discussion there which led to the matter coming before the Council. Edinburgh owed much to Dr. Berry while he was with us; it seems as though we shall soon see the reform he had so greatly at heart.

POST-GRADUATE STUDY AT EDINBURGH.—The reproach that there are no organised post-graduate courses at Edinburgh is to be removed this year. Arrangements are being made, and are now rapidly approaching completion, for an annual post-graduate course, to be held in September. Great interest is being taken in the scheme, and it is to be hoped that this attempt may prove successful and not be allowed to lapse as its predecessor did.

BELFAST.

THE DARNELL CASE.—A joint meeting of the Ulster Medical Society and the Ulster Branch of the British Medical Association was held in the Medical Institute Belfast, on Wednesday, April 25th, when it was reported that Dr. Darnell had decided not to proceed with an appeal against the recent decision in the case of *Tughan v. Darnell*. He was advised that even if the case were carried to the House of Lords, and the verdict upset on the ground of misdirection by the learned Chief Baron, it would only mean the fight beginning again from the first, probably on new grounds. The expense of an appeal is, of course enormous, and not to be lightly undertaken. Dr. Darnell's out-of-pocket expenses will probably amount to about £800, and it was decided to start a fund to assist him. A large General Committee was appointed, Dr. Leonard Kidd of Enniskillen (President of the Ulster Branch), and Dr. Wm. Caldwell (President of the Ulster Medical Society) being treasurers, and Dr. Cecil Shaw and Dr. Thos. Houston being secretaries.

ROYAL MEDICAL BENEVOLENT FUND OF IRELAND.—The annual meeting of the Belfast and co. Antrim Branch of this Fund was held in the Medical Institute, Belfast, on Friday, April 27th., Dr. Joseph Nelson, President, in the chair.—Dr. Purdon read the annual report, which showed the amount received from all

sources as £433, while recommendations for grants amounting to £145 had been made. Professor Lindsay was elected President for the ensuing year, Dr. Purdon was re-elected hon. secretary and treasurer, and the following form the Committee of the Branch:—Sir Wm. Whitla, Drs. St. Clair Boyd, Nelson, Dempsey, McKisack, McCullagh, J. W. Taylor, Whitaker, Leslie, W. Gibson, John Campbell, Fielden, and Cecil Shaw (all of Belfast), MacArthur (Greyabbey), St. George (Lisburn), Darnell (Bangor), Donnan (Holywood), Nolan (Downpatrick), and Gausson (Dunmurry).

THE HEALTH OF BELFAST.—The subject of the health of their city is being kept well before the Belfast public at present, partly on account of the very high death-rate, and partly on account of the rumours of a very gross piece of jobbery said to be contemplated by the Corporation in connection with the office of Medical Officer of Health. As noted in this column a fortnight ago, Professor Byers made a vigorous attack in a daily paper on the authorities for their attitude in regard to consumption specially, giving elaborate statistics from all over the United Kingdom to show the bad position of Belfast in the matter. The Chairman of the Public Health Committee, Dr. King-Kerr, has now replied, and charges Professor Byers with carelessly throwing statistics at the head of the public without proper collating, study, and analysis. Professor Byers may be trusted to take care of himself, and probably before he has finished with the worthy chair man that gentleman, like the historic parrot, will be "sorry he spoke."

Dr. King-Kerr's apologia occupies more than two columns of the daily paper, and is devoted first to proving that his committee held the most enlightened ideas on the subject of tuberculosis, but are prevented by the Corporation from carrying their plans into effect, and secondly to showing how mistaken Professor Byers is in his conclusions. It is impossible to condense the communication, but it is a very pretty example of the different conclusions to be drawn from "raw" statistics, and those "carefully collated, studied, and analysed"—some people might briefly call it "cooked"—by intelligent officials.

LETTERS TO THE EDITOR.

THE LUNACY QUESTION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—It is probable that those who read the letter signed "S." in the *Times* of Tuesday, April 24th, will agree with the views and opinions he expresses on the subject of Lunacy, and how to deal with those who suffer from it. The question, of greatest interest, however, wants to be treated with a little care and consideration. We must divide the class of lunatics who have little or nothing, financially that is, from those who have enough or far more than enough to provide them with all they want. The poor lunatic is a very different creature from the rich lunatic. The one depends entirely on others, the other does not depend on anyone. The rich lunatic is liable to suffer from those who can rob him; and so the law steps in to protect him from such influences.

The poor lunatic is a very different person, that is, in his relations to those who must support him. The question of Lunacy is not so much a medical question as a legal and social question.

When a poor creature's mental balance is disturbed and he becomes incapable of taking care of himself, and may be a danger to others, the chief question is to prevent others suffering, much in the same way that a small-pox case is isolated.

All that the law thinks of is to prevent the poor lunatic from being treated cruelly, and the rich lunatic from being robbed.

It would be well if "S." and others of our profession should consult with their lawyers and listen to their opinions when dealing with the difficult question of Lunacy.

It rests with the doctor to say when anyone is insane or not, and then with the law to decide what is best to do for them.

I am, sir, yours truly,

L.

THE MEDICAL ASPECT OF THE RECENT "RAGGING CASE."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—Your correspondent "Enquirer's" letter in your last issue goes to the root of the matter. For my own part I most unhesitatingly affirm my opinion that Surgeon-Major Whiston, in disclosing to his commanding officer the facts, or what he supposed were the facts, as to Lieutenant Kennedy's skin trouble, was absolutely unjustifiable. The point that concerns the medical profession is whether Surgeon-Major Whiston volunteered the information, or was dragooned into giving it by his colonel. After what one has learned about the lack of ordinary decency, to say nothing of military discipline, in the Scots Guards one would be surprised at no abuse of military authority in the interests of class privilege. It is to be hoped, Sir, that the matter will not be allowed to rest here, and that Mr. Haldane will not rest until the privileges and relations of Army medical officers are clearly defined. Meanwhile one trusts that the lesson of the "ragging" case will be taken to heart by every Army surgeon in the British Army.

I am, sir, yours truly,

AN EX-ARMY OFFICER.

Hampstead, April 30th, 1906.

OBITUARY.

DAVID SIMPSON, M.A., M.D., I.M.S.

WE regret to announce the death of Surgeon-Major David Simpson, Indian Medical Service, which took place in Madras on 19th ult. He studied Arts and Medicine at the University of Aberdeen, and afterwards attended the London Hospitals. Entering the home Army, he resigned and passed for the Indian Medical Service. He entered the Indian Service in 1887. In 1889 he was transferred to Burma, and afterwards served in the Chin-Lushai Expedition, for which he received the medal, and afterwards a clasp for the Manipur affair. In July 1891 he was appointed Second Surgeon at the General Hospital, Madras. He was transferred in 1900 as Civil Surgeon to Coonoor. In October 1903 he returned to the General Hospital, Madras, where he was appointed to succeed Colonel Sturmer, I.M.S., as Superintendent of the Maternity Hospital. He was buried with military honours by his regiment in Cathedral Cemetery, Madras.

LABORATORY NOTES.

THE CLAIRET VIERGE.

FROM the well-known importers, Messrs. Ingram and Royle, we have received samples of a new brand of a virgin claret, which we have found by laboratory tests to be of absolute purity, pleasant to the taste, and possessing an attractive bouquet.

To render it acceptable to even the most delicate stomachs, it has been subjected to a special treatment to eliminate any possible excess of tannin, and as will be seen from the analysis, the preparation is free from excess of alcohol, showing the process of fermentation has not been artificially arrested by the addition of some concentrated form of alcohol.

Our analysis shows this wine to have the following composition:—

Alcohol, 10.04 per cent. by volume.

Extractives, 2.22 per cent.

Mineral matter, 0.27 per cent. We find it to be free from foreign colouring matter.

As a light table wine at an extremely reasonable price, this should be highly appreciated by the great majority of claret drinkers.

PARANGANGLIN.

It is now some months since Messrs. Burgoyne Burbidge & Co. placed the new preparation, paranganglin, upon the market. They claim for this drug a remarkable therapeutic effect in gastro-intestinal atony, and in general asthenia. It is also used as a hæmodynamic in various hæmorrhages, as epistaxis, hæmaturia and hæmoptysis. In those forms of constipation which are due to intestinal torpidity, enemata of 100-200 cc. water containing 20-50 drops of paranganglin are recommended. If that troublesome condition can be relieved thereby, paranganglin will prove an invaluable drug. It is certainly worth the attention of practical physicians.

NEW BOOKS AND NEW EDITIONS.

THE following have been received since the publication of our last list:—

- BAILLIERE, TINDALL AND COX. (London.)
 The Dental Annual and Directory for 1906. A Year-Book of Dental Surgery and a Diary of Society Meetings. Fourth Year of issue. With 14 illustrations. Pp. 628. Price 7s. 6d. net.
 The Philosophy of Voice. By Charles Lunn. Tenth (Standard) Edition. Illustrated. Pp. 237. Price 6s. net.
 A Practical Guide to the Administration of the "Nauheim" Treatment of Chronic Diseases of the Heart in England. By Leslie Thorne Thorne, M.D., B.S. Durham, &c., &c. Second Edition. Illustrated. Price 3s. 6d. net.
 Aids to Surgical Diagnosis. By H. W. Carson, F.R.C.S. Pp. 140. Price 3s. 6d. cloth, 3s. paper.
 A Manual of Diseases of the Eye. By Charles H. May, M.D., New York, and Claud Worth, F.R.C.S. Edg. With 335 illustrations (20 coloured plates). Pp. 400. Price 10s. 6d. net.
 JOHN BALE, SONS AND DANIELSSON, LTD. (London.)
 Modern Surgical Technique in its Relation to Operations and Wound Treatment. By C. Yelverton Pearson, M.D., M.Ch., F.R.C.S. Illustrated. Pp. 392. Price 10s. 6d. net.
 On Means for the Prolongation of Life. By Sir Hermann Weber, M.D., L.R.C.P. Second Edition, enlarged. Pp. 104. Price 2s. 6d. net.
 P. BLAKISTON'S SON AND CO. (Philadelphia.)
 The World's Anatomists. By G. W. H. Kemper, M.D. Illustrated. Pp. 79.
 J. & A. CHURCHILL. (London.)
 An Essay on the General Principles of the Treatment of Spinal Curvatures. By Heather Bigg, F.R.C.S. Ed. Pp. 240. Price 4s. net.
 The Pharmacopœia of the Evelina Hospital for Sick Children, Southwark. Third Edition. Pp. 62. Price 1s. 6d. net.
 Heath's Manual of Minor Surgery and Bandaging. Thirteenth Edition, revised by Bilton Pollard, F.R.C.S. Pp. 409. Price 6s. net.
 On Physical Training in Schools. By W. P. Herringham, M.D., F.R.C.P., and The Influence on National Life of Military Training in Schools. By T. C. Horsfall. Pp. 20. Price 1s.
 Pathology, General and Special. By R. Tanner Hewlett, M.D., &c. Pp. 540. Price 10s. 6d. net.
 Rational Organotherapy. By Professor Dr. A. von Poehl, Professor Prince J. von Zurchanoff, Dr. Alf. von Poehl, Dr. P. Wachs. Translated from the Russian Text. Vol. 1. Pp. 239. Price 7s. 6d. net.
 HENRY J. GLAISHER. (London.)
 The Anæsthetic Technique for Operations on the Nose and Throat. By A. De Prenderville. Pp. 87. Price 3s. 6d. net.
 CHARLES GRIFFIN AND CO., LTD. (London.)
 A Handbook of Medical Jurisprudence and Toxicology. By William A. Brand, M.A., M.B., &c., &c. With Frontispiece. Pp. 287. Price 8s. 6d.
 HENRY KIMPTON. (London.)
 The Science and Art of Prescribing. By E. H. Colbeck, B.A., M.D., &c., &c., and Arnold Chaplin, B.A., M.D., &c., &c. Second Edition, revised and enlarged. Pp. 198. Price 3s. 6d. net.
 J. B. LIPPINCOTT CO. (London.)
 International Clinics: A Quarterly. Edited by A. O. J. Kelly, A.M., M.D. Vol. 4. Fifteenth Series. 1906. Pp. 312. Price 33s. yearly.
 LONGMANS, GREEN AND CO. (London.)
 Plant Response as a Means of Physiological Investigation. By Jagadis Chunder Bose, M.A., D.Sc. Illustrated. Pp. 781. Price 21s.

 The Frog: An Introduction to Anatomy, Histology, and Embryology. By the late A. Milnes Marshall, M.D., &c., &c. Edited by F. W. Gamble, D.Sc. Ninth Edition, revised and illustrated. Pp. 172. Price 5s.
 OBSTETRICAL SOCIETY OF LONDON.
 Transactions of the Obstetrical Society of London. Vol. 47. For the year 1905. Part 4, for October, November, and December. Edited by Herbert R. Spencer, M.D., and M. Handfield-Jones, M.D. Pp. 473. Price 10s.
 SMITH, ELDER AND CO. (London.)
 St. Bartholomew's Hospital Reports. Edited by A. E. Garrod, M.D., and W. McAdam Eccles, M.S., F.R.C.S. Vol. 41. Price 8s. 6d. With General Index. Vols. 21-40. Price 5s.
 SPOTTISWOODE AND CO., LTD. (London.)
 The Dentist's Register for 1906. Pp. 248. Price 3s. 4d.
 VEDDON AND PRITCHARD (Adelaide.)
 A Text-Book on Plague. By Dr. Tōlien Ishigami. Translated, enlarged, and illustrated by Donald Macdonald, M.B., C.M. Pp. 180. Price 22s. 6d.
 JOHN WRIGHT AND CO. (Bristol.)
 The Medical Annual: A Year-Book of Treatment and Practitioner's Index. 1906. 24th year. Pp. 654. Price 7s. 6d. net.

MEDICAL NEWS IN BRIEF.

The Cork District Hospital.

THE Cork Board of Guardians have decided to increase the staff of this hospital, and propose to appoint the present resident physicians to the posts of assistant visiting physicians at a salary of £100 a year each. They further propose to appoint two new resident medical officers at a similar salary. The latter gentlemen will be required to learn the Irish language within a year. In the course of an acquaintance with most parts of the County of Cork for nearly thirty years we have met in all perhaps some half dozen people who were unable to speak English fluently. If the Dublin Guardians were to act on similar grounds they should insist on the resident officers in the Workhouse Hospitals becoming acquainted with Yiddish. As the Cork medical officers will have the care of some 1,200 patients, we doubt if their professional duties will allow them sufficient leisure to carry out the requirement of the Board.

Temporary Mental Cases in Poorhouses.

THE Scottish Local Government Board have issued a circular to the governors of poorhouses in relation to the Departmental Committee on Poor Law Medical Relief. In certain poorhouses, it was suggested by that body it might be desirable to provide for the observation and treatment of persons showing symptoms of mental disorder believed to be temporary, and not to necessitate removal to an asylum. The Board think it right to bring this matter specially under the notice of House Committees, and to assist them in arriving at a decision, should they be disposed to favour the recommendation, a note of the conditions under which the Board are prepared to sanction the reception of such cases in a poorhouse is enclosed. These conditions provide in detail for the treatment of the patients on hospital lines.

PASS LISTS.

University of Durham.

THE following candidates have passed the Second Examination for the Degree of Bachelor in Medicine:—

Anatomy, Physiology, and Materia Medica.—Eldred Curwen Braithwaite (Honours—Second Class).

Pass List.—Harriett A. R. Apps, Charles E. L. Burman, Leslie W. Evans, Charles W. Greene, Arthur C. Greene, Claude P. R. Harvey, Edmund Hudson, M.R.C.S., L.R.C.P., Annie V. Mack, Herbert R. McAleenan, Stanley L. Randolph, Joseph A. Sacco, Rev. Robt. H. Smallwood, M.A., Theodore W. Stallybrass.

The following candidates have passed the Third Examination for the Degree of Bachelor in Medicine.—*Pathology, Medical Jurisprudence, and Public Health.*—Gertrude E. O'Brien and Stanley D. Metcalfe (Honours—Second Class).

Pass List.—Charles M. Brown, Gilbert I. Cumberlege, Ronald M. Davies, William H. Edgar, Helen M. Gurney, Hubert Shield, and John F. Young.

The following candidates have passed the First Examination for the Degree of Bachelor in Medicine.—

1.—*Elementary Anatomy and Biology, Chemistry and Physics.*—Jabez E. Dainty and Charles Marks (Honours—Second Class).

Pass List.—Frederick E. Chapman, Herbert E. Fullerton, William Reynolds, William R. E. Unthank, and Charles L. Wigan.

2.—*Elementary Anatomy and Biology.*—Everard C. Abraham, Isaac Bainbridge, John A. Caulcrick, Robert V. Clayton, Helen G. Clark, John Hare, John P. Higham, Howard T. Hunter, Laurence H. W. Iredale, George Eric W. Lacey, Herbert V. Leigh, Samuel Littlewood, George C. M. M'Gonigle, Charles O'Hagan, Eric H. Shaw, Henri R. G. Vander Beken, Stanley Worthington, and James Young.

3.—*Chemistry and Physics.*—Eliot W. Blake, Alexander H. Bower, Francis F. T. Hare, John H. Owen, Eliot J. Ramsbotham, Charles E. Reindorf, Madeline R. Shearburn, and Olivia N. Walker.

Royal College of Physicians, London.

At the ordinary quarterly Comitia of the college on Thursday last, April 26th, the following members of the college were elected to the Fellowship:—J. Hill Abram, M.D.Lond., of Liverpool; C. R. Box, M.D.Lond.; F. W. Burton-Fanning, M.D.Camb., of Norwich; E. F. Buzzard, M.D.Oxon.; M. Craig, M.D.Camb.; R. T. Hewlett, M.D.Lond.; J. Horder, M.D.Lond.; E. G. G. Little, M.D.Lond.; G. H. D. Robinson, M.D.Lond.; J. Purves Stewart, M.D.Edin.; J. H. Thursfield, M.D.Oxon.; and S. W. Wheaton, M.D.Lond.

The following licentiates of the college, having passed the required examinations, were admitted members of the college:—F. S. Langmead, M.D.Lond., St. Mary's; C. H. Miller, M.A., M.D.Camb., London Hosp.; and A. I. Simey, M.A., M.D.Camb., London Hosp.

The following candidates for the college licence, having conformed to the by-laws and regulations and passed the required examinations, received the licences to practise physic at this meeting:—C. B. M. Aldridge (L.R.C.P.Lond.), G. D. Alexander, G. Hely-Hutchinson Almond, J. S. Austin, A. S. B. Bankart, G. N. Bartlett, S. J. A. Beale, E. Beaton, W. Beck, C. J. E. Bennett, F. C. H. Bennett, C. M. Bernays, J. B. Binns, R. A. Bowling, S. J. Boyd, J. H. R. Brodrecht, H. G. Brown, R. Brown, O. Bruce, A. S. Burgess, P. Butler, H. Charles, W. W. D. Chilcott, J. Clarke, W. J. Cowan, D. Davidson, E. T. H. Davies, R. Davies-Colley, E. M. Dolan, J. J. W. Evans, H. W. Farebrother, R. V. Favell, S. Field, C. Fletcher, J. R. Foster, C. F. Fothergill, E. T. Glenny, H. Bootch, C. W. Greene, R. A. Greeves, A. H. Hardcastle, R. S. Harper, P. B. Harrison, A. Hawkins, G. M. W. Hodges, C. J. R. Hoffmeister, R. Holtby, E. T. C. Hughes, C. H. T. Illott, H. M. Inman, W. A. James F. S. Jones, T. J. Latham, T. St. L. Leyshon, A. R. Litteljohn, J. McAsh, C. M. MacLean, I. C. Maclean, E. A. Mascarenhas, G. P. Mills, A. Mülberger, H. C. Mulkern, J. O. Musson, A. H. Norris, J. J. Paterson, P. H. H. Pereira, A. R. Phelps, H. G. Phippen, P. A. Reckless, J. E. H. Roberts, F. S. Rood, A. M. Roome, S. J. Rowntree, D. W. Roy, A. Salmon, D. R. C. Shepherd, J. Smalley, H. Smith, J. E. Smith, L. E. M. Smith, H. S. Souttar, J. H. Spencer, C. Stanley Clarke, W. J. E. Stuttaford, G. W. Sudlow, A. K. B. R. W. Taylor, A. G. J. Thompson, G. S. Thompson, H. L. Tidy, J. F. Trewby, T. Turner, H. F. Vandermn, G. T. Verry, H. S. Vivian, G. Wachter, M. D. Wadia, H. R. S. Walford, J. Wallace, H. F. Warner, E. Wight and E. J. Wyler.

The Scotch Conjoint Board.

At the April meetings of the Scottish Conjoint Board of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, held in Glasgow, the following candidates passed the respective examinations:—

First examinations (five years' course)—Samuel R. Waugh, Hofmeyr Schimper, David L. Hutton, Joseph L. Pinto, Gideon du Preez, Willoughby E. P. Briggs.

Second examination (five years' course)—John C. Hawkes, Harold P. B. Tait, Franklin Joseph de Souza, Henry W. Turner, George W. Mason, David Welsh, Maurice E. Kayton, Samuel Abeyesundere, Thomas N. Wilthew, George F. Walker, Ferdinand Byrne, William R. Mackenzie, Robert M'Connell Blair.

Second examination (four years' course)—William C. Newton, Patrick J. A. Curtin.

Third examination—James F. Jeffries, Matthew H. Fleming, Thomas R. Eames, George Coats, Walter E. Barrett (with distinction); Graham Smith, John M. Muir, Evan A. S. Shaw, Alex. O'Flaherty.

APOTHECARIES' HALL OF IRELAND.—Mr. D. J. Boyle, having completed his Final Examination, has been granted the Diploma to practise Medicine, Surgery, Midwifery and Pharmacy.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

The importance of the Colon, as shown by a Case of Ulcerative Colitis treated by Operation. — Monier-Williams (*Brit. Med. Journ.*, April 7th, 1906) reports a case of severe ulcerative colitis, which was unimproved by three years of medical treatment. In 1900 the large intestine was opened close to the cæcum by G. R. Turner, as the patient passed 10 to 20 hæmorrhagic stools daily, was very emaciated and lost control of the sphincter ani. A specially devised plug and celluloid receptacle were constantly worn by the patient, so that very little fæces passed through the large intestine. A year after the operation the patient's general health was good, but the colitis was not quite well. After six months the patient commenced to lose flesh, became emaciated again without any apparent cause, and commenced to go down hill rapidly. As the serious hæmorrhages from the large bowel, which two years previously had necessitated the formation of an artificial anus, was now practically cured, it occurred to the author that the patient was in danger of losing his life for want of use of his colon, especially that most obvious of its functions, the absorption of water. To supply the necessary liquid, daily injections of saline were administered through the cæcal opening, about half a pint of which was absorbed per diem. The patient's condition soon improved. The injection treatment was continued for eight months, during which time the patient gained nearly a stone in weight. Twice the treatment had to be discontinued on account of severe attacks of purpura hæmorrhagica. On one occasion six and a half pints of blood were collected in thirty-six hours. On account of the hæmorrhages it became impossible to resume the colonic injections, and daily hypodermic injections into the right and left axillæ alternately were tried. These latter caused the patient much distress. To overcome this difficulty the patient was instructed to completely block the cæcal opening at night time. During the day the tube and celluloid receptacles were retained. The colon had therefore twelve hours of absorption and twelve hours of rest, its working hours being of sufficient duration to keep the patient in health, and its resting hours being of sufficient duration to keep in check the colitis, which though still not absolutely well, caused no inconvenience. This plan of blocking the plug at night-time was adopted in May, 1903, and the patient is still, nearly three years later, in perfect health. The author raises three points in connection with this case:—(1) The hæmorrhages seemed to be undoubtedly dependent upon the saline injections, though it took three and a half months to produce the effect. (2) Are we not justified in fearing that the scant respect shown by some surgeons to the colon may possibly be followed by disaster? (3) Do not those people who take every night an aperient pill of such a character as to produce on the following day a liquid evacuation interfere seriously with their own nutrition by not giving the large intestine a chance of useful absorption? S.

A Further Series of Cases of Congenital Obstruction of the Pylorus Treated by Operation. — Nicoll (*Glasgow Med. Journ.*, April, 1906) reports six cases of operation on infants, whose ages were 6, 3, 3, 6, 21, and 10 weeks respectively. The children were weakly and emaciated. The author considers gastro-enterostomy, lasting as it does from thirty to sixty minutes, a serious undertaking. Its mortality rate runs from 50 per cent. upwards, and it does nothing to remedy the stenosis unless combined with divulsion, which adds to the strain on the infant's feeble vitality. The operation performed in all six cases consisted in the application of the well-known

V-Y method, so widely useful in plastic surgery in general. The V incision in four of the cases penetrated the muscular coat only, and was closed (as a Y incision) by a single row of sutures. If this "submucous" plastic operation be adopted, it is necessary to combine with it divulsion, by means of a pair of forceps passed through an incision in the anterior wall of the stomach near the pylorus. In the two remaining cases the V incision was carried through into the lumen of the pyloric passage, and was closed (as a Y incision) by the customary two rows of the Czerny-Lembert suture. In a case so treated divulsion may be effected by forceps traction, the gastric incision being unnecessary. Clamps were used on the stomach and duodenum in all six operations. The operations took place between December, 1904, and September, 1905. Five of the patients are apparently cured. The infant five months old died from shock.

Case of Acute Uremia in which Decapsulation of the Kidneys was Performed. — East (*Canada Lancet*, March, 1906,) describes a case of acute nephritis in a girl, æt. 19. After suffering for some weeks from pain in the head and back and general malaise, the patient's urine suddenly became completely suppressed, none being obtained by the catheter. Convulsions, which became almost continuous then occurred, and marked Cheyne-Stokes breathing was present. Temperature 101°, pulse 120. When suppression of urine had lasted about 48 hours Dr. Groves operated without an anæsthetic. An incision was made over the left kidney and the kidney exposed. The capsule, which was very tense and congested, was incised along the whole length of the outer border of the kidney, and completely separated from it by the fingers. The right kidney was similarly treated. Both wounds were stitched up, and the patient returned to bed. The temperature rapidly rose to 104°. Five hours after the operation one drachm of urine was passed per catheter, at the end of six hours half an ounce, and at the end of seven hours, the same quantity. Throughout the next day and night the temperature remained at 105°. The urine increased slightly in amount at each catheterisation. Forty-eight hours after the operation the patient was in a semi-conscious condition. On the second day after operation eleven ounces of urine were voided, and the temperature became normal. On the third day twenty-two ounces were passed, and the patient was quite conscious. The patient made a rapid recovery. S.

A New Experience in the Diagnosis of Chorioidal Sarcoma in the Second Stage. — Buchanan (*Ophthalm. Review*, April, 1906) relates the following experience. In January, 1905, he saw a woman, æt. 56, who had cataract in both eyes, the right being the more advanced. In June, while waiting for maturation to be complete, she returned to hospital complaining of great pain in the right eye. Subacute glaucoma with very high tension was found. Eserine did not reduce tension, although pupil reacted readily to the drug. A large iridectomy was eventually performed, but the tension still remained high, and the eye was removed a week later. On dividing the eye a small pigmented sarcoma was seen growing from the neighbourhood of the optic disc, the retina was detached completely and pressed firmly against the back of the lens and ciliary body. To this latter condition of retina is due the non-reduction of tension on the anterior chamber being opened. The tension of the globe is always reduced by the opening of the anterior chamber in cases of pure glaucoma, and the second or glaucomatous stage of chorioidal sarcoma is

practically always the result of separation of the retina. If, then, a case is seen in which there is not satisfactory reduction of tension after opening the anterior chamber in a glaucomatous eye, it is probable that the condition is intra-ocular tumour. M.

Eye Injuries following Injection of Salt Solution—Dr. L. Alexander, Nuremberg (*Arch. of Ophthalmology*, January, 1906), in summing up his paper under the above title, says that the subconjunctival injections of 5 to 10% solution of Na Cl are followed by various injuries to the eye. Not only adhesions between bulbar conjunctiva and sclera, and partial gangrene of the conjunctiva (complications which have been seen to follow bichloride injections), but also transient changes in the cornea and lens occur. The subconjunctival injection of Na Cl and mercurial salts is very generally employed for various corneal and intra-ocular diseases, and so far no bad results or side-effects have been reported. Although, of course, many are prepared to admit that very often no good is gained by this method of treatment, Alexander expects that we shall soon hear more on this question from others who have had bad experiences, and he ventures to predict that distilled water will, in the future displace the Na Cl solutions. Pagenstecher has seen as good results following the use of distilled water, especially in cases of purulent corneal ulceration as with injections of sodium chloride solutions. M.

The Technique of Spinal Analgesia.—In a communication on this form of anaesthesia, Dr. Hackenbuch (*Zentralblatt f. Chirg.*, April 7, 1906), with an experience of eighty-five cases, recommends the use of stovain combined with suprarenal extract. It is not always easy to puncture the membranes of the spinal cord, if the patient's skin is thick and tough it grips the needle, if the patient is very stout it may be difficult to feel the space between the spinous processes of the lumbar vertebrae, for these reasons the author advises in all cases the following technique:—(1) The skin over the lumbar region should be thoroughly disinfected and well washed with normal saline solution. (2) Infiltrate the skin in the middle line just below the spine of the second lumbar vertebra with a cocaine solution. (3) Divide the skin in the middle line below the tip of the spinous process of the second lumbar vertebra, making an incision about half a centimetre long through the infiltrated area. (4) Introduce the puncturing needle through the wound for the depth of about one centimetre. (5) Remove handle of the needle and push the instrument steadily forwards until an abundant flow of cerebro-spinal fluid shows that the membranes of the cord have been pierced. (6) Inject the stovain and suprarenal solution. (7) Withdraw the needle with the syringe still attached from the wound, and immediately cover the incision with a small piece of leucoplast plaster. By taking these precautions, on the one hand, the danger of infecting the spinal canal is reduced to a minimum, and, on the other hand, it is scarcely possible to fail in obtaining spinal analgesia. Should, however, in a rare case the analgesia not prove to be sufficient, there is nothing to prevent a repetition of the stovain injection through the small wound, and in this way producing full analgesia without any danger to the patient. G.

Remarks on Acute Intestinal Obstruction.—In the course of his paper, H. Lillenthal (*New York Med. Jour.*, April 7th, 1906) touches first on the diagnosis of this condition, then urges the necessity for early operation in all cases, showing clearly the danger of delaying, he closes his paper with a few hints on the technique of operations for acute intestinal obstruction. General anaesthesia is almost always to be preferred to local anaesthesia, except where the patient is almost moribund. Preoperative gastric lavage should always be practised. If there is a mass, make a small incision over it, and explore before enlarging the incision. If there is no mass and no point of maximum tenderness then open in the middle line. It is of first importance to locate the seat of the obstruction, the accurate diagnosis may come later. If the gut is

under very high tension it is dangerous to manipulate it; such gut had better be emptied at once and the obstruction sought afterwards. To empty the gut, first pass a purse-string suture round a small area, then incise with a knife the centre of this area, turning the patient over on one side, Allow as much as possible of the bowel contents to flow out; when no more can be got away, tie the suture and turn the patient on to his back again. Repeat this procedure at two or three points if necessary. The obstruction, as a rule, can then be readily found, and the surgeon must then decide whether it is better to treat the case radically or to make a temporary enterostomy. Death from obstruction is rarely, if ever, due to the mere fact that the bowels do not empty themselves; it is usually due to strangulation and peritonitis, in which the distension plays an important role. Gastric lavage should never be practised before making the diagnosis and laying out the plan of action. G.

Remarks on the Diagnosis and Present Status of Treatment of Congenital Dislocation of the Hip-joints—Thienhaus (*Lancet-Clinic*, March 10th, 1906) reports three cases of congenital dislocation of the hip in children, treated by the bloodless method. Two of these were followed by perfect cure. In one case, six months after successful reduction, the child developed cerebro-spinal meningitis, followed by anterior polio-myelitis. This necessitated removal of the plaster and a relaxation of the congenital dislocation took place. The author has obtained many gratifying results from Lexer's method. Lorenz overcomes the obstruction of the adductor muscles by breaking or tearing them, which he accomplishes by striking the stretched adductors with the ulnar border of his hand. Lexer on the contrary finds that the resistance of the adductor muscles during reduction can be overcome by stretching these muscles gradually, and when reduction has been obtained, these untorn muscles are the most essential factor for the retention of the head within the acetabulum. The following conclusions are drawn by the author:—1. Congenital dislocation of the hip-joint is at the present time perfectly curable in 60 to 80 per cent. of all cases treated within the time-limit by so-called bloodless or bloody methods. 2. The best time for treatment is from the second to the fifth year. 3. The upper time-limit for bloodless reduction is ten years in unilateral cases, and eight years in bilateral cases. 4. In every case of congenital dislocation within the time-limit, the bloodless methods of reduction have to be tried first, and only after two or three attempts at bloodless reposition have been made without success or with bad functional results, the bloody methods come into play. 5. Cases over ten years of age with considerable shortening of the leg, and extreme adduction, can be benefited only by palliative operative procedures. These are for unilateral cases, the subtrochanteric osteotomy, and for bilateral cases, the pseudo-arthritis operation as advised by Hoffa. S.

NOTE.—A summary will appear each week in the following sequence:—

- (1) "Recent Medical Literature."
- (2) "Recent Surgical Literature."
- (3) "Recent Gynaecological and Obstetrical Literature."
- (4) "The Recent Literature of Physiology and Pathology."

London School of Tropical Medicine

THE following is a list of students who passed the examination in Tropical Medicine during April, 1906:—Capt. S. Anderson, I.M.S.; Capt. B. H. Dutcher, U.S. Army; Dr. G. J. Pirie (Colonial Service); and Dr. H. E. Arbuckle—with distinction. Dr. A. G. Eldred (Colonial Service), Dr. H. Kramer, Dr. P. H. MacDonald (Colonial Service); Dr. B. Moiser (Colonial Service); Dr. A. Reid, Dr. W. Rogers (Colonial Service), Dr. W. E. Rutledge, Dr. A. L. Wykham.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

MR. E. L.—Crowded out of our present issue; we hope to find room for the note in our next.

DR. TERRY.—Write to Messrs. Duncan, Flockart & Co. for their pamphlet on Ethyl Chloride.

L. S. H. (Buxton).—The average salary now obtainable by a locum tenens is four guineas (with second-class railway fares). Of late years the rate of remuneration has increased for that particular kind of work. The best plan is to put your name on the books of a good medical agency.

POOR LAW OFFICER.—The practical value of a diet estimation in regard to workhouse, prison, and other official administration is great. Brilliant results have been attained in that direction by simply estimating the output of nitrogen in relation to the nitrogenous input. There is no storage of nitrogen in the system, and in the healthy individual the one is balanced by the other. On these premises it is possible to detect errors in the input—otherwise, in the diet. A good authority on this subject is Dr. Wynter Blyth's book on "Foods."

H. S. R. (Liverpool) should refer the matter to his medical adviser, and ask him to recommend a specialist.

TU QUOQU.—We regret that our correspondent is dissatisfied. The matter was treated solely on its merits; but there are generally two sides to most questions.

MR. R. M.—Application must be made direct to the Home Office.
M. B. C. M. (Shrewsbury).—From inquiries, which we have made, we find that our correspondent has been misinformed.

THE EVERLASTING MICROBE.

What if "Baedili" roam about within
And fight the "Leucocyte" from day to day,
If they don't irritate the outer skin
We're bound to let the microbes have their way
("Alexins present on baedili prey")
Or poison them, the writers sometimes say,
If troublesome, we have the Rontgen Ray.

The jovial dustmen on the refuse boats—
No thoughts of microbes seem to trouble them,
The playful wind blows millions down their throats,
And yet they're more robust than many men—
Correct me if untruthful seems my pen;
But if you are unable to correct me,
No doubt you have the wish to disinfect me.

Then let bacteriologists arise,
The dustmen's ways consider and be wise.

A. D.

Meetings of the Societies, Lectures, &c

WEDNESDAY, MAY 2nd.

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Lewers, Dr. McCann, Dr. Tate, and Dr. J. I. Parsons. Short Communication:—Dr. Lewers: Three Cases of Epithelioma of the Vulva with History subsequent to Operation. Paper:—Dr. Herman: A Case showing (1) Uterine Contraction without Retraction; (2) Prolonged High Temperature of Nervous Origin.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. J. Cantile: Clinique. (Surgical). 5.15 p.m. Lecture:—Dr. G. E. Herman: The Prevention of Difficult Labour.

THURSDAY, MAY 3rd.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8 p.m. Oard Specimens will be shown by Mr. S. Stephenson, Mr. W. Roll, Mr. A. L. Whitehead, Mr. F. W. Edridge-Green, Mr. J. B. Lawford, Mr. L. V. Cargill, and Mr. M. S. Mayor. 8.30 p.m. Papers:—Mr. J. Taylor and Mr. T. Collins: Congenital Malformed Cystic Eye.—Mr. M. Davidson: Radium in the Treatment of Rodent Ulcer.—Mr. R. Pickard: Implantation Tumour of Iris.—Mr. Cargill and Mr. Mayor: Tuberculosis of Choroid.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m. Discussion on Asthma (opened by Dr. E. F. Willoughby).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m. Lecture:—Mr. A. H. Tubby: Surgical Diseases of Children.

FRIDAY, MAY 4th.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammermith, W.).—8.30 p.m. Discussion on Influenza, its Varieties and Sequels.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11 Chandos Street, Cavendish Square, W.).—5.30 p.m. Pathological Meeting. Specimens will be shown by Dr. E. C. Mackay, Dr. J. P. Parkinson, Dr. L. S. Dudgeon, Dr. E. Cantley, Dr. F. Langmead, Dr. G. Carpenter, Dr. J. G. Binnsell (Birmingham), Dr. E. Hobhouse (Brighton), Mr. G. Pernet, and others.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Dr. H. Tilley: Clinique. (Throat).

Vacancies.

Down County Infirmary.—House Surgeon. Salary £60 per annum, with board and residence. Applications to Dr. Tate, Infirmary House, Downpatrick. (See advt.)
Killarney District Lunatic Asylum.—Assistant Medical Officer. Salary £100 per annum and allowances. Applications to E. V. Griffin, Resident Medical Superintendent. (See advt.)
Littlemore Pauper Lunatic Asylum, Oxford.—Second Assistant Medical Officer. Salary £120 per annum, with furnished rooms in the Asylum and board. Applications to Thomas M. Davenport, Clerk of the Visiting Committee, County Hall, Oxford.
Royal Albert Hospital, Devonport.—Resident Medical Officer. Salary £100 per annum, with board and lodgings. Applications to the Chairman of the Selection Committee at the Hospital.
City Asylum, Gosforth, Newcastle-on-Tyne.—Assistant Medical Officer. Salary £140 per annum, with furnished apartments, board, and laundry. Applications to the Superintendent.

Appointments.

BELL, T., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Act for the Uppingham District of the county of Rutland.
BERGIN, W. M., M.B., B.S. Lond., Ophthalmic Assistant, Registrar and Tutor at Guy's Hospital.
BIRD, GEORGE WILLIAM HARVEY, M.B., B.O. Cantab., Medical Officer of Health to the Bridgwater (Somerset) Port Sanitary Authority.
GARDINER, PETER, M.D., C.M. Glasg., D.P.H. Lond., Medical Officer for the Camborne District by the Redruth (Cornwall) Board of Guardians.
HORGAN, J., L.R.C.P. and S. Edin., L.F.P.S. Glasg., Certifying Surgeon under the Factory and Workshop Act for the Kenmare District of the county of Kerry.
JOHNSTONE, JOHN LLOYD, M.R.C.S., L.R.C.P., Clinical Assistant to St. John's Hospital for Diseases of the Skin, Leicester Square.
KERRAWALLA, M. P., M.D. Brux., L.R.C.P. and S. Edin., Clinical Assistant to the Evelina Hospital for Children.
LAMB, J. S., L.R.C.P. and S. Irel., Certifying Surgeon under the Factory and Workshop Act for the Cretway District of Queen's County.
LONGRIDGE, C. J. NEPMAN, M.D. Vict., F.R.C.S. Eng., M.R.C.P. Lond., Registrar and Pathologist to Queen Charlotte's Lying-in Hospital, Marylebone Road, N.W.
MAY, WALTER, J., L.R.C.P., M.R.C.S., L.D.S., Lecturer on Dental Mechanics at the Royal Dental Hospital of London, Leicester Square.
PEARSE, JAMES, M.D., C.M. Edin., Medical Officer in charge of Troops at Trowbridge (Wilts).
RICHARDS, P. A. ELLIS, F.I.C., F.C.S., Lecturer on Dental Metallurgy at the Royal Dental Hospital of London, Leicester Square.
RICHMOND, JAMES ROBERT MARR, L.R.A., Medical Officer of Health of the West Penwith Rural District (Cornwall).
ROLSTON, JOHN R., M.R.C.S. Eng., Honorary Ophthalmic Surgeon to the Royal B. I. sh Female Orphan Asylum, Devonport.
SHEEHAN, M., M.R.O.S., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Act for the Mallow District of the county of Cork.
TROM, GEORGE, M.R.C.S., L.S.A., Honorary Consulting Surgeon to the Royal Albert Hospital, Devonport.

Births.

GATES.—On April 21st, at Via Palestro A., Florence, Italy, the wife of Edward A. Gates, M.D., M.R.C.P., of a son.
INMAN.—On April 28th, at The Lower Mill House, Bedhampton, Havant, the wife of William S. Inman, M.B., of a son.

Marriages.

BARBER—HOWLETT.—On April 24th, at St. George's Tomland, Norwich, Hugh Barber, M.D. Lond., son of Mr. and Mrs. Christopher Barber, of Sheffield, to Ethel Mary, daughter of Mr. and Mrs. J. G. Howlett, of 36 Bracondale, Norwich.
HEFFERNAN—TURNER.—On April 18th, at the Church of St. Michael and All Angels, Croydon, William Hilton Heffernan, L.R.C.P. Lond., M.R.O.S. Eng., of Wimbledon Park, eldest son of John Harold Heffernan, C.B., of Liverpool, to Gladys Lloyd, third surviving daughter of James Turner, Netherton, Croydon.
PENDRED—MATTHEW.—On April 23rd, at St. Barnabas, Addis Road, Kensington, Vaughan Pendred, M.D., F.R.C.S. Eng., of Coventry, eldest son of Vaughan Pendred, M.L.M.E., and Mrs. Pendred, of Orailth, Streatham, to Beatrice Elisabeth, daughter of Dr and Mrs. Mordaunt Matthew, of 22 Holland Road, Kensington.
STEELE—ROGERS.—On April 28th, at St. Peter's, Eaton Square, London, Charles Fran' is Steele, M.B. Lond., M.R.O.S., L.R.C.P., eldest son of Charles Steele, M.D., of Clifton, to Anita Russell Rogers, youngest daughter of the late Mr. Edward Dresser Rogers, D.L., of Rockley, Denmark Hill, London.

Deaths.

HUTTON.—On April 24th, at Lulworth House, Birkdale, Lancashire, the residence of her son, D. M. Hutton, M.D., Eliza Peddie, widow of David Hutton, Esq., of Parkfield Road, Liverpool, in her 69th year.
JAMIESON.—On March 8th, at Dalwin, Falkland Islands, Lowther A. Jamieson, L.R.C.S.I., youngest son of the late Edward L. Jamieson, of Heriotage, Orkney.
SCOTT.—On April 24th, at Bury Lodge, New Malden, Surrey, John Scott, F.R.C.S., late of Harley Street, London, aged 95.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

Vol. CXXXII.

WEDNESDAY, MAY 9, 1906.

No. 19.

NOTES AND COMMENTS.

A Public Medical Protest. Obviously much good work may be done by the medical profession in the education of the public as to the worthlessness of quack medicines and methods. Some time last year an effective protest was raised in a north country town at a public lecture given by a notorious electrical charlatan, who professed to cure many maladies, curable and incurable, by the exercise of powers bordering upon the omnipotent. A medical man in the audience asked a number of awkward questions as to diagnosis and other precise details, and the meeting broke up in confusion. Last week a well-known Llanelly resident, Dr. Williams, attended a lecture by a faith-healer, Mr. Howton. The latter is reported to have said that Christ was about to revisit the earth, as evidenced by recent earthquakes and other upheavals. He stated that recently he himself visited an asylum and cast out a devil from one of the patients. Dr. Williams thereupon promptly demanded the name of the patient and of the asylum where this miracle was performed. Howton replied he would give the information privately. A heated argument ensued and eventually the lights had to be turned out to clear the hall. Well may we crave for higher standards of State education!

Gold Scalpels. The golden sickle of the ancient Druids is a traditional implement strangely at variance with modern ideas. As a soft, ductile metal, gold has never appealed to mankind as fitted for the making of cutting weapons. However, Dr. J. F. Vaughan, of Los Angeles, says the *Tribune*, has invented a means of tempering gold, and has made scalpels, hypodermic and suture needles, and other surgical instruments from the hardened metal. The advantage claimed for the gold blade is, that it is almost perfectly smooth and makes a clean incision that unites without a scar, in contrast with the wound left by the serrated edge of the ordinary steel knife. The latter, moreover, is liable to rust spots, which are apt to lodge bacteria and hence to convey infection to the tissues. Should the advantages of Dr. Vaughan's invention be confirmed, he will have bestowed a valuable boon upon our surgical *armamentarium*.

More Caution. The dismissal last week of the extremely grave charge against a young London physician will be received with much general satisfaction throughout the profession. From the

first it seemed absolutely incredible that a young man of exceptionally brilliant attainments should abuse a position of trust by assaulting children under his care. The fact that the whole of the evidence came from defective children clearly imposed both upon the investigating magistrate and the prosecution an unusual amount of responsibility. The outcome of the inquiry has been the complete vindication of the accused. The magistrate accepted without reserve the medical testimony that charges without foundation were often made by mentally defective children. The London County Council were under the circumstances justified in bringing the matter forward. In future, however, that body will in our opinion act wisely by taking the obviously prudent precaution of having a nurse present at all medical examinations. Such a step would prevent the future possibility of bringing unfounded charges of the kind. As a matter of simple caution it would be desirable for all medical men to ask for the invariable presence of a nurse in dealing with patients of deficient intellect.

Students and Casualties.

The recent unfortunate occurrence at a leading London hospital raises once more the question as to the methods in force in the casualty rooms of what are known as "teaching hospitals." In this particular instance a patient with a large abscess pressing on the œsophagus was sent away on the ground of there being no room for admission. On being taken to another hospital the patient died shortly after operation. The gravity of the condition could hardly have been overlooked at first by an experienced man. Without a full knowledge of the facts of the case it would be impossible to pronounce any judgment as to its merits or demerits. It may be pretty safely asserted, however, that there is considerable room for improvement in the casualty departments of many of the great hospitals. Too much responsibility is left in the hands of students or of newly-qualified residents. Under the constant supervision of an experienced senior man there would be little likelihood of turning away patients in a dying condition. If in a great hospital a few beds cannot be reserved for urgent cases the administration of that particular charity stands more or less self-condemned. That there are serious difficulties in dealing with a never-ending stream of casualties we must all recognise.

LEADING ARTICLE.

THE WATER SUPPLY OF LONDON.

THE task of supplying a vast city like London with water is truly gigantic. Some years ago the remittent failure of the supply in the East End of the Metropolis gave rise to a vast deal of annoyance and discomfort, to say nothing of the injury to trade and the danger to the public health. The problems presented to us in the water supply of London run on much the same lines as those in the great cities of the rest of the United Kingdom. The questions of purity and quality, of adequacy in amount, of sufficiency of pressure, of constancy of supply, and of the hundred and one details connected with collection, storage, and distribution are no less vital to the citizen of Manchester, of Glasgow, of Dublin, and of all other great centres than they are to the Londoner. As things stand the London water supply cannot be regarded as satisfactory. As everyone knows, the supply is drawn practically from two sources—the Thames and the Lea. Both those waters are extensively polluted with sewage above the intakes of the water companies. In the light of modern scientific knowledge that state of affairs cannot be accepted as safe or salutary. It is perfectly clear that sewage polluted water can be rendered safe by sterilisation, but no attempt has ever been made by the companies to sterilise the water before delivery. They trust to sand filtration, a method that is not only subject to various fallacies, but may at any moment break down. Last year the question of the Thames as a source of drinking water supply was brought forward at the London meeting of the Public Health Congress. The author of an article on the subject dwelt on the fact that Londoners were content to drink water from that river after it had undergone extensive sewage contamination. He proved that such pollution was constant and universal, and quoted specific instances of accidental sewage pollution on an extensive scale. The main conclusion arrived at was that if Londoners are content to go on drinking diluted sewage they should at least insist on having it sterilised. We are glad to see that the question is not to be allowed to drop out of sight. Sir Alexander Binnie, the eminent engineer, has recently stated the emphatic opinion that if the present pollution of the water supply continues the time will come when there will arise an epidemic which will startle the world. That view will be unhesitatingly endorsed by the great majority of medical experts in public health. The history of water-borne typhoid and cholera is alone sufficient to condemn any system that supplies water that has been once polluted by bowel bacteria, pathogenic or otherwise. Were a single case of cholera to be imported into the

Thames Valley above the companies' intakes the only obstacle in the way of a vast and terrible outbreak of cholera would be the admittedly imperfect chain of sand filters. As it is there is a vast deal of enteric fever in the metropolis the origin of which is unknown. While it is true that there is no evidence to prove that this infection has been distributed through the domestic water supply, yet, on the other hand, there is the positive fact that in the course of an extensive sewage contamination much typhoid excreta must necessarily reach the Thames. In view of the fallacies that surround the bacteriological examination of water the reports of individual experts must be received with some reserve. It would be a matter of great scientific interest as well as of sound value to the community were a Government investigation by a body of the best scientific experts obtainable appointed. One of the fundamental necessities of a good standard of public health is a pure water supply, and no amount of favourable reports by more or less interested expert examiners can do away with the primary fact of sewage contamination. One member of the Metropolitan Water Board is reported in a London paper recently to have stated with regard to the Lea:—"The effect of the present system is this, that about two or three million gallons of sewage effluent is actually being drunk every day in the East End of London alone. The question arises, therefore, whether it is desirable for financial reasons that this state of things should continue." The last sentence strikes at the root of the matter. Should private enterprise be permitted to control so important a matter as the water supply of a country? Further, if private enterprise be necessary, to what extent should the State insist upon a well-considered standard of purity and carefully guarded sources of origin before granting a monopoly in the provision of one of the necessities of life?

NOTES ON CURRENT TOPICS.

The Story of a Heart.

We drew attention a few months ago to the interesting story of the autopsy on the body of Paul Jones, performed more than a hundred years after his death. This period, long as it is in proportion to the usual time that elapses between death and autopsy, is brief enough when compared to that which elapsed between the death of Rameses II. and the microscopical examination of his heart in Paris in the present year. Assuming that the heart in question is indeed that of Rameses II., then some thirty-one centuries have elapsed since it ceased to beat. The organ reached the Louvre recently in one of a series of vases reputed to contain the viscera of the monarch named, and was found to be of horny hardness, requiring the use of the saw for section. Fine slices made with a razor showed, however, that the section was undoubtedly composed of heart-muscle. The hardening was due to embedding in

natron and various resinous substances. We understand that there is some question as to whether the organ is that of Rameses II. or of one of his sons, but there seems to be little doubt that it comes at any rate from his period.

The Election of Direct Representative to the General Medical Council.

We have always been forward in advocating the extension of the principle of direct representation of the profession on the General Medical Council, and we have taken our part in directing professional opinion to the point. The great fault of the present constitution of the Council is that the members are nominated not by the members of the medical profession, but by certain limited bodies, to wit, the various licensing corporations. What is required is election on a fair democratic basis. A danger which threatens all democracies, however, is "caucus" rule, or "bossism," and the medical profession has need to exercise great care in guarding itself against a pseudo-democracy which would be little or no improvement on the aristocracy to which we are subject at present. We believe that the recent tendency to pre-arrange by caucuses the elections of direct representatives is one fraught with danger to our freedom. We view with grave suspicion the decision of the British Medical Association to "run" a candidate or candidates at the next election, since the choice of such candidates is sure to fall into the hands of a clique who will be able to impose their will on the more or less indifferent masses of their fellow members. Direct representatives should win their seats by personal merit, and not because of their nomination by any society or group of the profession, no matter how wealthy or important that society or group may be.

Dust.

A LECTURE, interesting in matter and vigorous in delivery, was given by Sir Dyce Duckworth before the National Health Society on "Dust." It is precisely by diffusing among the public exact ideas on such subjects as the nature and dangers of dust that good educational work in domestic hygiene is done, for the traditional notions prevalent are as unscientific as they are vague. The sources of town dust and the evils to which it gives rise were brought under review by the lecturer, and the inaction of local authorities in the prevention of smoke and their carelessness in the way they collect and remove dust were strongly condemned. To those who possess libraries the problem of preventing books from harbouring dust and the difficulty of keeping shelves properly clean is an ever-present one, and to such Sir Dyce Duckworth gave a tip of great value which he had learned from the librarian at 20, Hanover Square. The plan adopted at that library is to remove the books *en masse* and to sprinkle the shelves with wet sawdust. The latter readily catches the dust, and when it has done its work

it can be raked on to the floor and thence swept up without parting with its burden. Sir Dyce Duckworth is evidently no lover of motorists, and he spoke in strong terms of the selfishness of those who drive their cars through the country roads raising clouds of dust and deluging gardens, crops, and cottages with debris from the road. It is difficult to conceive of a more effectual method of scattering road-germs than is adopted by motorists, and now that the automobile is becoming so popular one would not be surprised to hear of widespread outbreaks of diarrhoea and other alimentary complaints owing to the contamination of food and drink by motor-raised dust.

Rate-aided Hospitals.

At a special luncheon at the Mansion House, the other day, held to inaugurate the preparation for a bazaar in connection with the Royal Waterloo Hospital, an important speech was made by Mr. Walter Long. Speaking before the Duchess of Albany, and a distinguished company, Mr. Long took occasion to deplore the fact that in London, the richest city in the world, it was hardly possible to find a hospital that was not in want of funds. That, indeed, is unfortunately true, and it leads to the still more deplorable fact that it is necessary for hospitals to try to raise money by the mercenary method of bazaars and festival dinners. No sober citizen can but regret that it is only possible to minister to the needs of the sick poor by tickling the appetites of the healthy rich, but that this is so is amply demonstrated by the frequency with which these entertainments succeed one another during the periods when fashion ordains that its devotees should reside in London. Mr. Long expressed his belief that the time was at hand when the majority of the hospitals would have to seek support from the rates as they could not go on for ever depending entirely on voluntary support. It is well that this prospect should ever be before the minds of the people of London, for the opinion of a shrewd public man like Mr. Long is not to be passed lightly by. The burden on the rates of contributing wholly or partially to hospital support would be heavy indeed, and the elasticity of administration which, intelligently worked, secures so many advantages would give way to the hide-bound red-tapeism of Government machinery. Medical education undoubtedly would suffer, and all personal interest in individual hospitals would be submerged in the common apathy with which the London ratepayer regards the manner in which his money is expended.

Vanity, Quackery, and Death.

WE frequently have occasion to comment on the vanity of women and the rapacity of those who trade on that weakness, but though such women may waste their money, quacks secure it and newspaper proprietors cut in for a big slice, it is seldom that more than moral harm is done by their transactions. Two recent cases of violent

death draw attention rather forcibly to certain traits distinguishing these classes of the community. An inquest was held on a shoe-operative in the Midlands who was foolish enough to have believed certain advertisements of pills and cream for the complexion, and to have treated herself with them in order to remove freckles which Nature had ordained she should be possessed of, but which evidently stood in the way of connubial advancement. After taking the pills the girl became exceeding ill with hæmatemesis, and soon after died of exhaustion. At the autopsy a gastric ulcer was found, but no signs of irritant poisoning, so that the jury returned a verdict in accordance with the medical evidence. It is of course impossible to say with certainty that the pills were the direct cause of death, but it is just probable that a hard body such as a pill lodging in or about a gastric ulcer might determine rupture of an artery. At any rate the folly of self-medication and the danger of quack advertisements was abundantly illustrated. In the second case a woman at Bristol, having one leg shorter than the other, put a salt cellar in her shoe to supply the deficiency. By this means was caused a fatal fall. These are some instances in which the modest fee of a general practitioner may be sufficient to prevent people losing their lives unnecessarily.

The Doyen Cancer Cure.

THE news that Dr. Doyen had formally adopted the yeast cure for cancer was cabled from the Lisbon Medical Congress, and published in leading newspapers in various continents. It appears, however, that the news was unfounded, and that Dr. Doyen has not abandoned his well-known method of anticancerous vaccination. We have been favoured with the text of M. Doyen's communication to the Congress, in which he gives his most recent results with vaccines prepared from the *micrococcus neoformans*.

The Opium Traffic.

As alcohol is to the Western World, so is opium to the East. Traced to their ultimate principles both intoxicants are narcotic poisons, and both minister to some mysterious morbid craving of mankind. Both are valuable medicinal agents, and both, alas! are on the other hand answerable for a vast toll of misery, disease, and death entailed upon their victims. Curiously enough, the United Kingdom is directly or indirectly responsible for much of the mischief in both cases. As a vast producer and consumer of alcohol she becomes answerable for an untold sum of human woe. The vast dependency of India, again, is the chief centre of the opium trade. The total value of that drug exported from India in 1904-5 was £7,082,295, of which amount no less than £5,541,040 was consigned direct to China. Those who know anything of the baneful effects of opium upon the human frame can to some extent realise the sum total of moral and physical degradation

involved in those statistics. There is a good deal to be said, indeed, in favour of the contention held by many philanthropic persons that the Indian opium traffic forms an indelible stain upon our imperial escutcheon. Unfortunately, India is a poverty-stricken country. The opium revenue for the years mentioned amounted to £4,050,266, a colossal sum that renders the task of the reformer extremely difficult. If money can be found for punitive expeditions, surely it should be forthcoming to combat a great social canker.

A Curious Professional Accident.

THE risks attached to the exercise of the medical profession are manifold indeed, but there appears to be always room for some fresh combination of the old factors. A curious accident in connection with the extraction of a tooth occurred not long since at a village near Craig-y-Nos. Dr. Richards, a local man, in performing the operation, splintered a small portion of the tooth, which flew off and struck him in the eye. In the evening the eye became inflamed, and it was then found that the cornea had been pierced by the fragment, which had set up septic infection. Unfortunately, the course of an ophthalmitis of that kind is no less rapid than serious. In this case we regret to learn that Dr. Richards will almost certainly lose an eye.

A Rebellious Local Authority.

THE Chipping Sodbury District Council seem bent upon drawing the eyes of the nation upon their affairs. They have planted the revolutionary standard and hurled defiance at the Local Government Board. The latter central authority issued a provisional order uniting eleven neighbouring urban and rural districts for the purpose of appointing a medical officer of health. This arrangement did not secure the approval of the Chipping Sodbury Council, who, insisted upon their right to retain their own medical officer—Dr. Bond. After a long discussion, the following amendment was carried by 12 to 4:—"That inasmuch as we have before pointed out that we are in a very large and important district, we still adhere to our original expression of opinion that we should have a medical officer of health of our own, and beg to protest against the attitude that the Local Government Board have taken up against this Council, and again ask them to allow us to sever our connection with the combination." Should the Council push matters to the bitter end, there will be a good deal of interest in the near future to occupy the minds of the good folk of Chipping Sodbury.

The Budget.

MR. ASQUITH'S first Budget did not come as a surprise, and therefore can hardly be said to have provided a disappointment to the professional classes. Men of all political complexions are prepared to give the Chancellor of the Exchequer a

chance before criticising his work, and a chance of doing anything heroic he certainly has not yet had. On the other hand, it is necessary that voices should be raised in good time before any further proposals are entered upon with regard to the national finances. It is held in a general way by democrats that direct taxation of the rich is achieved with rough justice by the imposition of the income-tax, but we can only say that such justice as is achieved is very rough indeed. The well-to-do dividend-drawer can well afford to give a twentieth part of his income to the general funds of the State, but it is far otherwise with the small professional worker who gains his living by the sweat of brow and brain. An income-tax of a shilling in time of peace has been pronounced by so great a fiscal authority as Mr. Gladstone to be a standing danger, and though it is four years since we were at war the tax has not yet been brought below that figure. On the Committee Mr. Asquith is appointing to deal with the graduation of the income-tax it must be impressed by every available means that the doctor who wrests a bare living by attending the ailing poor is a far poorer man than many of his income-tax free patients and lives a life that the majority of them would never cease to grumble at. If the income-tax be not graded to distinguish between the dividend-earned income and the sweat-acquired income, and if it be not adjusted so that the small man pays proportionately less than the rich, the financial policy of the Government will not only be illiberal but flagrantly unjust.

Oyster Depreciation.

WE cannot affect the slightest sympathy with the oyster-dealers who are deploring the falling off in their trade. Mr. George Tabor, a leading Billingsgate dealer, is reported to have said recently that £4,500,000 was lost to the trade yearly through lack of a little commonsense, and that we ought to imitate the Dutch Government and have an official inspection of oyster-beds every year, so that every oyster should bear a Government certificate of soundness. Remarks of this kind show the utter lack of responsibility that pervades the minds of many of those who cater for the public wants. It is a disgrace and a scandal that certain oyster-dealers should for years have purveyed contaminated oysters to the British public and caused a yearly death and sickness bill which it is impossible to estimate with any accuracy. The least possible punishment for such heinous carelessness is that the culprits should suffer in pocket; for ourselves we can think of few sentences consonant with humanity which would be too bad for them. The Government should be under no obligation to put themselves to expense in order to prevent disease-germs being foisted on their subjects by wealthy merchants who will not set their own houses in order. Local authorities who allow their sewage to contaminate oyster-beds are amenable to the common law, and without excusing them we un-

hesitatingly condemn the conduct of the proprietors of such beds in putting their death-dealing wares on the market. The oyster trade is said to be reviving. We can only express the hope that when the mollusc that our contemporaries delight to call "the succulent bivalve" regains its popularity, it will do so purged from the bacteria passed from the human intestine.

Meeting of the General Medical Council.

WE understand that the Spring Session of the General Medical Council will commence on Tuesday, May 22nd, under the presidency of Dr. Donald MacAlister, when the reports of Committees, Amendments as to Standing Orders, and other important matters will be considered.

PERSONAL.

ON May 5th, H.R.H. the Princess Royal laid the foundation stone of the new buildings of the Bolingbroke Hospital, Wandsworth Common, London.

WITH deep regret we notice amongst the list of the victims of the recent Guernsey wreck the name of Miss Frances Waller aged 12, the daughter of Professor Augustus Waller, F.R.S., Director of the Physiological Laboratory in the University of London.

The next half-yearly dinner of the London-Glasgow University Club will be given at the Trocadero Restaurant on May 25th, under the presidency of Sir Thomas McCall Anderson, Regius Professor of Medicine in the Glasgow University.

THE President of the Royal College of Physicians of London will represent that ancient body at the forthcoming quarter-centenary of the University of Aberdeen in September next.

ONE of the most striking pictures in the Royal Academy's exhibition in London this year is the portrait group, by Mr. J. S. Sergeant, of Professors William Welch, Halstead, Osler and Howard Kelly, painted for the Johns Hopkins University.

DR. CHARLES A. WIGAN has been elected Chairman of the local District Council of the Portishead (Somerset) District.

THE annual dinner of the Volunteer Ambulance School of Instruction will take place in the Trocadero Restaurant on May 17th (the anniversary of the relief of Mafeking), under the presidency of Surgeon-General Keogh.

BARON TAKAKI, surgeon-general of the Imperial Japanese Navy, is giving a course of three lectures on May 7th, 9th, and 11th, from 5.30 to 6.30 p.m., at St. Thomas's Hospital, on "The Preservation of Health Among *Personnel* of the Japanese Army and Navy," based on his experiences in the late Russo-Japanese war.

DR. THOS. F. DEWAR, of Arbroath, was last week entertained at a banquet given in his honour by his fellow townsmen previous to his assuming the important post of Medical Officer of Health for Forfarshire. The company numbered about 100, among whom were several members of the profession.

A CLINICAL LECTURE ON THE GENERAL CYSTIC DEGENERATION OR TRANSFORMATION OF THE KIDNEYS IN THE ADULT.*

By JOHN LINDSAY STEVEN, M.D., F.F.P.S.G.,

Physician and Lecturer on Clinical Medicine, Glasgow Royal Infirmary; Honorary Librarian, Faculty of Physicians and Surgeons, Glasgow.

ABOUT sixteen years ago, when I first, as pathologist, became intimately acquainted with the contents of the Pathological Museum of the Glasgow Royal Infirmary, two specimens in the section devoted to renal disease arrested my attention and excited my astonishment. They were the kidneys of a patient who had suffered from enormous cystic disease of these organs; the description of the specimens is to be found in the present printed catalogue, p. 295, Series vii., O, 3 and 4. The specimens are at least thirty-five years old, and the account of them, which is very brief, has been continued from that contained in the first printed edition of the catalogue published by my old teacher, Professor Joseph Coats, in 1872. The right kidney weighed when removed from the body 84 ounces, and the left appears to be about the same size.

"The cysts vary in size from a line to 1½ inch in diameter. The contents of the cysts are very varied; some contain clot with calcareous matter mingled.

"History.—Removed from the body of a man, æt. about 60. A private case. The cause of death was unknown and no renal disease was suspected."

Such is the brief account that has come down to us of these two remarkable specimens, which I show you to-day. There are now some seventeen or eighteen specimens of cystic disease of the kidneys in the museum, many of which have been added by my friend and colleague, Dr. David Newman, who has written a valuable chapter on the subject in his book, entitled, "Renal Cases: a Series of Selected Clinical Reports and Surgical Studies" (Maclehose, Glasgow, 1899). The only specimens, however, at all approaching in size to these I have just referred to were added in 1899 by my friend and successor as pathologist, Dr. Charles Workman. If you compare Dr. Workman's preparations with the older ones you will see that they are quite evidently specimens of the same disease. As Dr. Workman has made a very careful examination of these specimens it will be instructive if I read to you the account of them, which he has published in the last edition of the Catalogue of the Museum. Specimen numbered "VII. O. 17, consists of the left kidney with its capsule stripped off to show the great alteration of structure. It weighed 65 ounces. VII. O. 18 consists of half of the right kidney. The other half has been presented to the Museum of the Western Infirmary, Glasgow.

"The kidneys have a remarkable appearance, resembling masses of pudding-stone made up of pebbles of very various colours. This seems to be due to the fact that into some of the cysts hæmorrhage has occurred, and this in varying degree in different cysts. In some there is caseous material; in some even calcareous deposit. Microscopic sections were made from several parts of the kidney and stained in various ways (Van Giessen's method and alum carmine). These show that the cysts are mostly lined with a single layer of epithelium, and that between the cysts there is still a considerable amount of comparatively healthy kidney substance with tubules and Malpighian tufts.

"In the liver in this case careful examination showed areas translucent from the presence of cysts. These were generally about the size of small peas, were scattered singly, and numbered in all about a dozen. Microscopic sections of these showed them to present a structure identical with the cysts of the kidneys.

"History.—Patient was admitted as 'an urgent

abdominal case' on February 27th, 1899. He had been ill for the last three months, but had become much worse during the days previous to admission. He had no vomiting, no diarrhoea and no headache. Frequent enemata were given on admission, and they gave great relief. Abdomen was greatly distended, and hard masses were felt on either side, but more especially on the right. Urine was bloody, abundant in albumen, without casts, and small in amount. Patient did fairly well till the evening of March 1st, 1899, when he became drowsy. Twitchings succeeded, and later he became blind. Twitchings increased, and ended in convulsions about 4.5 a.m., March 2nd, 1899, in spite of active treatment. Symptoms were typically uræmic."

During life the patient was under the care of my colleague, Dr. James A. Adams.

It is obvious, I think, that all the specimens of cystic kidney in our museum (most of which I have placed upon the table for your inspection) are not of the same nature, but there can be little doubt that the two cases to which I have specially directed your attention are illustrations of the same affection. I have referred to them in detail, so that you may have some idea of the renal lesion which I believe to be present in the patient whom we have carefully examined together in Ward 8, and whose clinical history and physical signs I am now about to relate to you in full. In my experience cystic transformation of the kidney of this kind is rare, and in twenty-five years of pathological and clinical work I cannot remember to have met with a case before. Dr. Newman has found 105 cases recorded in literature, and Dr. George F. Still has "been able to collect together thirty-five cases of cystic liver associated with cystic kidney" (*Path. Soc. Trans.*, 1898, Vol. XLIX., p. 158). You will see, then, that though comparatively rare the condition is well recognised, and latterly has been minutely investigated and described. Indeed, if you refer to Sir William Robert's "Treatise on Urinary and Renal Diseases" (4th edition. London, 1885, p. 560), you will find that cases have been put on record since the time of Richard Bright, in 1835, and on page 567 you will see a woodcut which might serve as an illustration for one of the specimens I have been showing to you to-day. No doubt the great advance that has been made in renal surgery during the last twenty years has led both to a more accurate knowledge of the clinical history, and a greater skill in the diagnosis of this affection. I shall now relate to you the clinical history of our case, for which I am indebted to my house physician, Dr. W. B. Jack. Dr. Jack's report is dated November, 1905, and the patient has been re-admitted (March, 1906) for observation, and for this clinical lecture. The physical conditions and the symptoms are practically unchanged, and so the account which I am now to submit to you sufficiently describes this patient's present condition, which you have also had an opportunity of investigating for yourselves.

CLINICAL HISTORY OF CASE.

Mrs. M., æt. 33, housewife, was admitted to Ward 8 of the Glasgow Royal Infirmary on November 25th, 1905, complaining of pain in the left side of the abdomen of eleven, and of swelling of four months' duration.

About eleven months ago the patient was delivered of a six months' child, still-born. During the last six

* Delivered to the Author's Post Graduate Class in the Glasgow Royal Infirmary, March 29th, 1906.

weeks of her pregnancy she suffered from swelling of her feet and legs as high as the knees, but this disappeared after the labour. No medical man was in attendance, and she was assisted by a neighbour. So far as she is aware, everything was natural. Soon after her recovery, however, she began to be troubled with a pain in her left side, dull in character, but sufficient occasionally to keep her awake at night. She did not pay much attention to the pain, and went about her ordinary household work. About four months before admission, she noticed a swelling in her left side, and the pain became more severe. The pain in the left lumbar region tended to shoot down into the inguinal region, but did not affect the act of micturition, which was not increased in frequency. There had been progressive loss of strength and of appetite in the last four months, and for a week before admission she vomited a great deal after her food; latterly also headaches have been troublesome. Menstruation has been normal, and the bowels have been regular.

Her previous health had been very good, and the six-months' child mentioned above is the only one she had borne. She has had no miscarriages.

The family history is unimportant. She is an only child; her mother is alive and well. Her father is dead, the cause of his death being unknown. Her circumstances are comfortable.

PRESENT CONDITION, NOVEMBER 26TH, 1905.

The patient lies on her left side, breathing easily. The face is rather pale, and there is puffiness under the eyes. The pupils are dilated, but react to light and slightly in accommodation. The lips and conjunctivæ are well coloured; the tongue moist and clean, the teeth carious. The general condition is very poor, and there is complaint of slight pain in the abdomen.

The abdomen is somewhat irregularly distended. It bulges a little forwards at the umbilicus and at the sides. The abdominal wall is loose, poorly developed, and easily moved on the underlying structures. On palpation, two large swellings are made out, one situated in either flank and definitely separated from each other. They are, roughly, about the same size, larger than a cocoa-nut, and, if anything, the left is the larger. They extend from about the level of the tenth rib in front to rather lower than the level of the anterior superior spines of the ilium. The swellings approach one another towards the middle line anteriorly, but the fingers can easily be pushed between the anterior borders of the two tumours. They have a fairly firm consistency, and an irregular lobulated outline. No fluctuation can be made out in them. On palpation behind, they are easily felt in the region usually occupied by the kidneys, and are somewhat freely movable. There is tenderness on pressure over the tumour of the left side, the pain shooting downwards into the inguinal region. Percussion over the tumours is dull.

Hepatic dulness is separable from the tumour dulness, and measures three and a half inches in the mid-clavicular line, the lower border of the liver not being palpable below the costal margin. The splenic dulness measures about 2½ inches.

The heart and lungs present quite normal characters, the apex beat being situated in the fourth interspace 3½ inches to the left of the middle line, and the sounds being of normal quality.

Urine.—During the first twenty-four hours of residence the patient passed 72 ounces of pale urine, sp. gr. 1006, reaction acid, slight flocculent deposit, albumen a distinct trace. No blood was ever observed; no sugar.

The microscope reveals numerous vaginal epithelial cells. A few leucocytes, but no tube casts. The accompanying table gives the details of the daily quantity of urine, and of the chemical analysis for eleven days.

The patient was examined yesterday (December 3rd, 1905) by my surgical colleague, Mr. J. Hogarth Pringle. Nothing was found in the bladder, and the urine was

obtained separately from each kidney by catheterising the ureters. Less urine was obtained from the left ureter, and that from the left contained 1¼ gr. of urea per ounce, as against 3½ gr. per ounce obtained from the right kidney. In both specimens a trace of albumen was found. The diagnosis of double cystic kidney was confirmed by Mr. Pringle, who did not recommend operative interference.

On December 4th, 1905, I entered the following note in the ward journal:—On inspection of the anterior abdominal wall this morning it is found to be irregular in shape, this irregularity being due to the presence of two prominent swellings, one, the larger, on the left side, occupying the whole of the lumbar and the left part of the umbilical region. The other, the smaller, causes a distinct prominence in the right lumbar region, and is situated as nearly as possible in the space between the anterior superior spine and the costal margin. In the anterior axillary line the vertical measurement of this prominence is three inches, and its anterior margin is situated in the line of the point of the eighth rib. Both swellings when palpated are found to be due to the presence of large rounded masses in the abdomen, with somewhat irregular and finely nodulated surfaces. On bimanual palpation, the swellings are felt to pass deeply into the lumbar regions posteriorly, whence they can be freely moved forwards by pressure from behind. The fingers can be passed quite easily between the costal margin and the surface of the tumour on the left side, which could not be done were the swelling due to an enlargement of the spleen of similar size. It is further quite obvious that the tumour is related to a part more deeply situated in the abdomen than the spleen. On the whole, the phenomena indicate greatly enlarged, and probably cystic kidneys.

December 8th, 1905.—The patient feels better, and there is much less tenderness on the left side of the abdomen than before. The edge of the liver can now be felt just below the costal margin on deep breathing.

December 22nd, 1905.—The patient went home to-day.

Such, then, are the physical signs and the clinical history of this very interesting and comparatively rare case. I propose in conclusion to make a few

remarks on the pathogenesis and diagnosis of the affection.

Cystic disease of the kidneys may be of various kinds—viz.: (1) Simple unilocular urinary cysts, a very frequently-occurring condition, of no great clinical importance, and apparently of congenital origin. (2) Multiple cysts due to chronic interstitial nephritis, also a frequent condition, whose pathology is well understood, and in which the cysts do not attain to any great size. (3) Hydatid cysts of the kidney, on the whole a less frequently met with condition, but of which I have published one case, in which the daughter cysts of the parasite were discharged *per urethram* during life, and of which the clinical diagnosis was confirmed later by *post mortem* examination (*Glasg. Med. Journ.*, vol xxii, 1884, p. 427). (4) General cystic degeneration or transformation of the kidney, the rarest form of all, of which the case you have examined to-day is, I believe, a typical example.

Considerable difference of opinion has all along existed as to the pathogenesis of cystic transformation of the kidneys. I do not think that any theory which attributes this condition to chronic interstitial nephritis or to obstruction of the uriniferous tubules, however caused, can now be entertained. There are two theories of the causation of cystic transformation of the kidneys which are deserving of careful consideration. First, there is the theory of congenital malformation, which has been well stated by Dr. George F. Still in the following paragraphs from the paper in the *Pathological Transactions* to which I have already referred you:—

"It seems, therefore, only reasonable to attribute the condition to the same cause at all ages, and the most satisfactory explanation which has yet been suggested is, I think, that of Mr. Shattock (*Path. Soc. Trans.*, Vol. XXXVII., p. 287), that the cystic condition is the result of a congenital malformation, the mesonephros having blended with the metanephros in the development of the kidney (p. 159). In view of this fact it seems reasonable to suggest that the cystic liver associated with cystic kidney in adults is, as in the infant, a congenital condition, and further, that as the cystic kidney is almost certainly a malformation, so the cystic liver also is simply a malformation, and not the result of disease" (p. 163).

In this connection then, the association of cystic transformation of the kidney with a similar condition of the liver, as in Dr. Workman's case, which I have described to you, is of importance in the pathology of the affection. It is worthy of note, however, that in Dr. Workman's case the cystic transformation of the liver was very slight as compared with that of the kidneys, and that in our patient there was no enlargement of the liver, phenomena which might be advanced in support of the second theory, which is that the cystic transformation of the kidney may be of the nature of a neoplasm, an opinion supported by Dr. Workman, who has written to me as follows upon the subject:—

"With regard to cystic degeneration of the kidney, my opinion of its being a neoplasm and not an ordinary degeneration is in part from the histological appearance of the cysts, showing a well-developed secreting membrane resembling the lining membrane of the cysts of the thyroid, while the kidney tissue exists in fair amount between the cysts showing both Malpighian bodies and various forms of tubules, though these are, of course, compressed to some extent by the cysts. The cysts are not just degenerated and dilated tubules. Another reason for this view is, that the disease is not confined to the kidneys, but I believe nearly always involves other organs, such as the liver, the pancreas, or suprarenals. In the case you refer to there were a considerable number of small cysts in the liver, and in another case which I saw there was a greater cystic development in the liver than in the kidneys."

These statements give some idea of current opinion as to the pathogenesis of this interesting affection,

and I think that there are cogent arguments which might be advanced in support of either. In support of the congenital hypothesis it is of interest to remember that cystic transformation of the liver and kidneys is sometimes associated with other congenital malformations or deformities, such as undescended testis, polydactylism, webbed fingers, &c. (Still). On the other hand, the small amount of cystic change in the liver in Dr. Workman's case (about a dozen small cysts in all) might be taken as indicating that the affection of the liver was secondary to that in the kidneys.

As regards diagnosis, I have not very much to say. In a case such as I have demonstrated to you there could not be any great difficulty, as a study of the clinical history and physical signs of our patient abundantly proves. The chief difficulty of diagnosis would of course be experienced in the earlier stages of the affection, before the organs were palpable. At this stage it is probable that the symptoms would resemble those of chronic interstitial nephritis. When, however, the double renal tumour is palpable the question of cystic transformation at once arises. I believe the affection is always double, though the greater advancement of the lesion on one side may occasionally lead to only one kidney being palpable. Under such circumstances the difficulty of diagnosis might be very great, and perhaps could only be removed by catheterisation of the ureters or an exploratory incision. There are two symptoms of importance which should be taken carefully into account in estimating the diagnosis of a doubtful case, more especially as they may be leading indications of totally different affections—viz., hæmaturia and renal pain. Dr. Newman has pointed out that in cystic kidney hæmorrhage may occasionally be very profuse, although it was not present in our case. Renal pain resembling renal colic may be present, as it was in our case. Taken by themselves, then, these symptoms do not help us much, but if they are associated with the presence of a double, slightly nodulated renal tumour, there should be no great difficulty in the diagnosis.

Treatment, except on general principles, in cases of cystic transformation of the kidney must always avail very little; if the affection be congenital, the fact that a man may live with the lesion present in an advanced degree till the age of sixty years would indicate that there is not necessarily any immediate danger to life. Certainly any radical operative interference, in view of the extreme probability of the lesion being double, is not to be recommended.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's number will be by George Palmerton Newbolt, M.B., F.R.C.S.Eng., Surgeon to the Royal Southern Hospital, Liverpool, and Dean of the Clinical School, on "Tropical Abscess of the Liver" (Illustrated).

ORIGINAL PAPERS.

THE MODERN TREATMENT OF GONORRHEA.

By ARTHUR BALL, M.D., F.R.C.S.I.,
Assistant Surgeon, Sir Patrick Dun's Hospital, Dublin.

GONORRHEA, although one of the commonest of diseases, is still a much more serious affection than the general public or, indeed, many of the medical profession seem to realise. While many cases get well with little or no treatment, yet it must be admitted that gonorrhœa sometimes produces serious complications and is the most potent cause of sterility in both sexes. Now that the declining birth-rate is becoming yearly a more serious problem, the treatment of gonorrhœa by some method which will cure without complications, and render the patient free from infection in the shortest possible time, is a matter deserving considerable attention.

Gonorrhœa may be defined as an acute specific

urethritis caused by inoculation with the gonococcus. The disease commences in, and at first involves, the anterior urethra in the male—that is the urethra in front of the compressor urethræ muscle, and is called acute anterior urethritis. When the gonococci pass the compressor urethræ muscle posterior urethritis follows; this frequently comes on without any increase of the symptoms. A neglected or badly treated anterior gonorrhœa usually invades the posterior urethra by the end of the first week. The frequency of this extension is variously given by different observers. Gadassohn holds that 60 to 70 per cent. of anterior gonorrhœas invade the posterior urethra. Finger places the extreme figure at 80 per cent.; Taylor between 80 and 90 per cent. This frequent extension of the disease to the posterior urethra is largely responsible for the seriousness of the disease, for gonococci may, once they have infected the deeper parts of the genital tract, remain for almost any number of years alive and still capable of transmitting the disease indefinitely.

As gonorrhœa starts as a purely local disease involving a delicate mucous membrane, it is reasonable to treat this by local applications in such a manner that the inflamed surface is cleansed and soothed without being irritated, thus allowing the patient's normal powers of resistance to the organism to act to greatest advantage.

Of the multitude of cures for gonorrhœa which seemingly have been so widely exploited, the great majority are wholly inefficient. The irrigation method largely used in America and on the Continent, but as yet little practised in this country, gives results unquestionably better than any other form of treatment at present known.

Goldberg has summed up the publications of all who have written favourably or otherwise on this method with the following results:—

60 per cent. of acute gonorrhœas were cured within ten days.

30 per cent. of acute gonorrhœas were cured within fourteen days.

10 per cent. of acute gonorrhœas were not cured.

Of the last mentioned the failure was clearly attributed to indulgence in alcohol and coitus in half the number; the remaining 5 per cent. were not explained. During the past three years, in the out-patient department at Sir Patrick Dun's Hospital and in private I have treated almost every case of acute gonorrhœa by this method, and am fully satisfied with the results obtained. The following is the method adopted, being a modification of that of Janet popularised in America by Valentine. As soon as the patient presents himself the discharge is examined for the gonococcus; this is important with a view to treatment and prognosis. I have recently met with three cases of acute urethritis which were not caused by the gonococcus; these readily yielded to treatment different to that necessary to cure gonorrhœa.

Apparatus.—A glass irrigator capable of containing a quart of fluid is suspended by a cord passing over a pulley fixed to the ceiling, so that the height of the irrigator can be rapidly adjusted according to the part of the urethra under treatment: about ten feet of rubber tubing; some form of urethral irrigating nozzle such as Valentine's, which is provided with a semi-circular metal shield, which prevents the fluid returning from the urethra splashing the operator or the patient. A convenient shield to an ordinary glass nozzle can be made by cutting in half one of the all-rubber bulb urethral syringes and passing a glass nozzle through each half, thus making two complete nozzles which can be sterilised by boiling. Nozzle and shield combined, made of one piece of glass, can be obtained from Gentile of Paris; these are very convenient, but are, unfortunately, easily broken.

Solution.—The best results are obtained by using an extremely weak solution of permanganate of potash, 1 gr. to the quart being sufficient to commence with; the most suitable temperature is 100° F. According to Janet the permanganate of potash has a peculiar

action on the urethra. "It occasions a slight œdema of the mucous membrane: while this lasts not a single microbe can be found in the secretion. The success of the permanganate treatment seems to show that the gonococci are so influenced by the alteration of their culture ground, dependant on the œdema, that they cease to grow, hence if this condition of the urethra is sufficiently maintained, the complete destruction of the microbes is sure." (White and Martin).

The strength of the solution recommended above is much weaker than that advised by Janet, for Valentine has found that Janet's solution "for some reason seems too strong to use in this country"—i.e., America. This same holds good for Ireland, and the above strength of the solution is even weaker than that recommended by Valentine. The antiseptic powers of the solution used in irrigations must be practically nil, and I have for some time held the opinion, but have not yet carried it into practice, that irrigations with sterilised normal saline solution two or three times daily would probably cure the disease as quickly, or perhaps quicker than permanganate of potash, but to carry out this treatment one would almost require the patient to remain in hospital during the treatment. A continuous irrigation of normal saline, for some hours at a time, with the patient lying quietly in bed might considerably shorten an acute gonorrhœa.

Treatment of acute gonorrhœa.—The diagnosis having been established, the anterior urethra is irrigated with permanganate of potash, 1 gr. to the quart. The reservoir being only two feet above the urethra the patient may, when the anterior urethra alone is under treatment, stand, or sit on the edge of a chair. The glans, prepuce, and urethral orifice are cleansed by allowing the stream from the nozzle to flow over them. The nozzle, with the stream still flowing, is then inserted into the meatus; the fluid is permitted to run gradually at first, with full force later. In anterior urethritis the fluid is allowed to run out of the meatus by the side of the nozzle. It is advisable to continue the irrigation until the entire quart is used up, and with a conical nozzle the amount of distension of the urethra can be so adjusted that very little pain is caused, even with an acutely inflamed urethra. The first irrigation sometimes causes a slight amount of pain, but the relief given to the distressing symptoms is such, that even the most troublesome class of patient to treat—i.e., the lowest labouring class, who object as a rule to any treatment other than "a bottle"—will readily return for further treatment.

This treatment should be carried out once or twice daily, gradually increasing the strength of the solution until 4 grains to the quart is reached by the end of the second week, before which time the discharge has usually ceased. If the gonorrhœa does not appear to be rapidly subsiding at the beginning of the second week, the possibility of involvement of the posterior urethra must be considered. The diagnosis of posterior urethritis is best made by the "two glass test" of Sir Henry Thompson, which is as follows. The patient is told to pass about half the urine into one glass and the remainder into the second. The first urine passed in the morning should be used for the test, so as to observe all the discharge which has accumulated during the night. In this way a much more accurate indication of the actual state of affairs is presented than if the test is performed later in the day, when the patient may have swallowed large quantities of fluid and so diluted the urine. If the first specimen of urine is turbid and the second clear, the indication is that the anterior urethra alone is affected and that all the purulent discharge has been washed out of the urethra by the clear urine coming from the bladder. If both the first and second specimens of urine are turbid, the indication is that the gonococcus has extended backwards and infected the posterior urethra, the compressor urethræ muscle preventing the discharge formed in the posterior urethra passing forwards into the anterior urethra; during the night the discharge accumulating behind this muscle easily enters the

bladder, mixing with the urine collecting there. Cystitis, of course, will produce this turbidity of the urine, but in this case the turbidity is constant. In posterior urethritis the turbidity of the second portion is very variable, and if the "two glass test" is made during the day the second portion may be quite clear, enough discharge not having collected to flow backwards into the bladder. Hence the importance of obtaining the first urine passed in the morning when testing for posterior urethritis.

When the posterior urethra is found to be infected the entire urethra should be irrigated. This is most readily done with the patient in the recumbent position. The anterior urethra first having been irrigated, the reservoir is raised from 6 to 9 feet above the urethra in order to give sufficient pressure to overcome the compressor urethræ muscle. The meatus is held tightly about the nozzle, and the flow of fluid is gradually increased by relaxing pressure on the rubber tube until it overcomes the compressor muscle and bladder sphincter, and the fluid enters the bladder. If the muscles do not quickly relax, continue the hydrostatic pressure and order the patient to breathe deeply and make efforts at urination, until the fluid enters and fills the bladder; the nozzle is then withdrawn and the patient micturates. This procedure is repeated two or three times at each sitting.

No doubt it may be said that treatment such as I have outlined above is unsuitable for out-patient hospital work, as the patients frequently cannot attend regularly for treatment, and of course it is undesirable, or impossible, to supply them with the necessary apparatus. If a patient attends for treatment three times a week he is usually well in three weeks. I generally prescribe benzoate of soda in ten grain doses; this drug relieves the pain on passing water and renders the urine slightly antiseptic, and is considered by the lower class of patients to be the important part of the treatment.

Space prevents us entering into all the arguments in favour of the irrigation treatment, but not the least is the fact that I have not yet seen epididymitis develop in a patient treated by this method. I think that injections of irritating fluids in the hope that the gonococci will be killed is largely responsible for this complication, especially when the patient is given a syringe and a bottle of lotion and performs these injections himself, without in many cases using any method of sterilising the syringe. In most cases of chronic gonorrhœa it is usual to find other organisms present, probably in many cases the result of septic applications of treatment.

Chronic Gonorrhœa.—If the patient is not well in three weeks, it is desirable to examine the urethra with the urethroscope, when certain areas of mucous membrane will be found still inflamed. This condition should be treated with a solution of silver nitrate, 8 grs. to the ounce of water, which is increased in strength (according to the reaction on the inflamed area) to 10 or 15 grs. This quickly renders the urethra healthy in most cases, but occasionally some infected follicles are seen when the general redness has subsided; these may be cauterised with solid silver nitrate, pure carbolic acid or the galvanic cautery. The occasional passage of a large bougie if the meatus will admit it, or the dilatation of the urethra with an expanding dilator, often hastens the cure, but the passage of a number 12 bougie is of very little use, as this will not distend the bulbous or prostatic portions of the urethra. Bougies up to 18 or 20 English scale have often to be used.

I have now outlined the treatment for acute gonorrhœa, and for one which passes into the chronic stage. Frequently cases come for treatment with a slight morning drop or gleet. When this condition has existed for a long time (sometimes several years), and has resisted almost every form of treatment, it takes a very careful urethroscopic examination to locate the seat of disease; when this is found to be the prostate gland, massage per rectum and dilatation of the prostatic urethra are indicated. Recently I have had satisfactory results with high frequency electricity

applied by an electrode passed into the prostatic urethra. The frequency of micturition in one case, in which cystitis was also present, was completely relieved by two applications of this current.

From the literature of the subject one would gather that the cause of gleet is usually to be found in the involvement of the posterior urethra. But in almost all the cases I have examined I have found a tender granular spot in the anterior urethra; in three cases this was ulcerating and commencing to cicatrise, and the position in all was about an inch and a half from the meatus. If this spot is treated first it sometimes happens that when it is cured the patient is well; and if not, it renders the treatment of any lesions further back much easier both for the patient and the surgeon.

When the gonococci have penetrated the deeper parts of the posterior urethra they seem to remain almost indefinitely, and the treatment to effect a cure is very prolonged. Some recent work offers great possibilities of curing these difficult cases. When they have existed for a long time they seem always to render the subjects victims of almost hopeless neurasthenia, which renders treatment a matter of great difficulty, as a prolongation of treatment tends greatly to increase the neurasthenia.

The address in Surgery, at the seventy-third meeting of the British Medical Association last year at Leicester, by C. J. Bond on "Ascending currents in mucous canals and gland ducts," offers the explanation of the tendency for gonococci to penetrate deeper and deeper into the affected individual when the normal powers of resistance to infection are lowered. It also suggests the solution of the question of treatment once the condition has become chronic. For if these ascending currents carry the gonococci into the inaccessible ducts and glands we may use them for carrying something which will destroy the gonococci. I myself, and I am sure many others, have been working on these lines for some time, but so far I have not hit on a suitable substance which will act this way. Some insoluble powder seems most suitable, and with insufflations of calomel into the urethra I got one apparently good result which was, however, not permanent, and I have not been able to confirm it. Silver nitrate is undoubtedly the most efficient substance in chronic gonorrhœa, but is turned into silver chloride almost immediately it is applied, and its beneficial action was supposed to be due to its stimulating antiseptic action; but in view of the work of Bond it is reasonable to suppose that the insoluble particles of silver chloride are carried up the ducts and into the infected glands and inhibit the growth of the organisms. Acting on this hypothesis I am at present trying the effect of silver chloride powder applied through a urethroscope tube, and I hope to publish the results on another occasion. Meanwhile I hope that others with larger opportunities of treating these cases will investigate further on these lines.

The Oponic Theory of Wright of St. Mary's Hospital offers hope for some of these cases. Possibly the patient's powers of resistance to the organism can be raised by inoculation with a killed culture of the gonococcus. Wright has shown that massage of a joint affected with gonorrhœal rheumatism frequently increases the "protective substances" in the patient's blood for this organism, by causing an auto-inoculation of the patient's body. This possibly gives the explanation of the undoubted fact, that passing a large bougie sometimes cures a troublesome chronic gonorrhœa, for the bougie may cause an auto inoculation with gonococcus products. In treating these very chronic cases by inoculation I am sure it would also be necessary to isolate the other organisms usually present, and inoculate with the organisms which it is found the patient has least resisting powers to; this will possibly not always be the gonococcus.

Lastly, the question of complete cure must be considered. By cure freedom from infection is understood not freedom from symptoms. Although unfortunately amongst hospital out-patients, the latter is considered all that is necessary, they generally cease attending as

soon as this has been attained. To decide that a patient is free from infection is often difficult and may involve a great responsibility. The following, in brief, are the important points.

A week after all evidence of gonorrhoea has ceased, treatment should be stopped and all restrictions as to diet and alcohol removed. If the morning urine is then found to be clear and free from shreds, the patient is probably cured. A few days later the contents of the prostatic glands should be expressed, by massage per rectum; if the secretion contains no gonococci the patient may safely be considered cured. Many cases present greater difficulty; when the posterior urethra has been attacked the urine will be found to contain shreds day after day. When these consist of pus and epithelial cells, but contain no gonococci, the urethra should be irritated by an irrigation of the anterior urethra with one per cent. silver nitrate, or corrosive sublimate 1,5000. This will produce a discharge lasting from 8 to 36 hours. If no gonococci are found on three successive mornings after the irritation, the patient may be pronounced to be cured with reasonable certainty.

THE TREATMENT OF SCIATICA AND NEURALGIA BY SUBCUTANEOUS INJECTIONS OF SALT WATER.

By R. P. E. LAUNOIS,

Physician to the Hôpital Tenon, Professor of Medicine.

[REPORTED BY OUR FRENCH CORRESPONDENT.]

It was in 1889 that for the first time I had recourse to the subcutaneous injection of small quantities of artificial serum for the relief of sciatica, and since that time this therapeutical procedure, which was suggested to me by an article in a foreign periodical, has been in constant use at the Hôpital Tenon. This method, moreover, has for a long time been turned to account in the out-patient department of the hospital and the favourable results thereby obtained have been published in the thesis of one of my students. (a)

It is hardly necessary to point out that sciatica (neuralgia of the lumbo-sacral plexus) possesses an individuality of its own, so that it may fairly be treated as a morbid entity. In spite, however, of its autonomy it may assume very different characteristics, sometimes indeed it appears to involve all the branches of the nervous plexus, sometimes it is limited to the trunk of the nerve or its two principal divisions, the internal and external popliteal nerves, or it may affect only the terminal ramifications of the nerve. Moreover, and this is of very great importance, by remarking the nature and intensity of the disturbances to which it gives rise one may sub-divide the cases, as Landouzy does, into sciatic neuralgia and sciatic neuritis.

The therapeutical method which I am about to describe applies exclusively to the former of these two conditions, that is to say, cases in which pain and functional trouble predominate and in which there is no amyotrophic process. This, indeed, is the form most frequently met with as shown in many collected statistics, notably those brought together by Samuel Hyde (*Lancet*, May 9th, 1906). It occurs mostly in adults and is more frequent in men than in women. It seems to have a predilection for the right side. Lastly, sciatic neuralgia is very prone to recurrence, at long or short intervals.

Without dwelling on the symptomatic manifestations of sciatica it may be well to insist on the fact that the permanent pain is liable to be aggravated by paroxysmal exacerbations, involving the whole nerve or its branches, that it may elect domicile, so to speak, in particular spots, pressure on which determines more or less painful sensations. These spots, which correspond to the *points douloureux* localised by Valleix, possess some clinical importance; they are as follows—following the direction of the lumbro-sacral plexus we

have: the lumbar sacro-iliac, iliac, gluteal, ischiatic, retro-trochanteric, femoral, popliteal, patellar, peroneal, malleolar, dorsal of foot, and external plantar. The subcutaneous injections should be made just over such of these spots as correspond to the maximum of pain.

The operative *technique* is simple enough. The skin is sterilised by washing with soap in distilled water, followed by friction with a tampon of cotton wool steeped either in alcohol or in ether, pure or containing a suitable proportion of perchloride of mercury. The syringe must be sterilised and should have a capacity of 10 cc. The needle, which should be of irido-platinum in order to allow of its being heated, must not be of too large calibre or too long.

The liquid to be injected consists of sterilised water containing a certain proportion of chloride of sodium. To begin with, and for some time, we made use of what is commonly known as Hayem's physiological serum, which contains seven parts per thousand of chloride of sodium. Recently, however, we have modified its composition by the addition of sulphate of sodium according to the following formula:

Sodii chloride, 5 grammes.

Sodii sulphatis, 10 grammes.

Aquæ dest, 1,000 grammes.

The addition of the sulphate of sodium presents the advantage of doing away with the trifling pain that usually follows the injection of the solution of pure chloride.

The solution to be injected should be tepid or slightly warmed, and 5 cc. should be injected over each painful spot. The same patient may receive at the same sitting, without inconvenience, four, five, or six injections. The depth to which the needle is introduced will vary of course with the anatomical structure of the part and the situation of the nerve trunk. In some cases the injection is really hypodermic, while in others it is deeply interstitial, as for example in the gluteal region.

After the injection there remains a slight tumefaction over the spot which can be made to disappear at once, by gentle massage with the finger tips.

The method may be applied for several days following without hesitation, but in refractory cases it is well to repeat it only every other day.

We have naturally tried to explain to ourselves why the introduction of salt water into the tissues should be virtually painless, whereas the injection of pure water often gives rise to more or less disagreeable sensations. The outcome of modern research in biological chemistry appears to afford the desired explanation by enabling us to appreciate the importance of the isotonia of solutions employed for injection into the organism.

In his extremely interesting researches into the metamorphism of the nervous system, Constensou endeavoured to elucidate the mechanism of the action of revulsions applied over the points of maximum pain or along the track of the nerve. He points out that in order to bring about the subsidence of the painful crises which are characteristic of neuralgic affections we may act upon two important segments of the nervous metamera, the central and the peripheral segments. Substances introduced by the epidural method act upon the former, whereas it is on the latter that liquids act, especially those holding saline constituents in solution, when injected in the neighbourhood of nerve trunks or, still better, into contact with their peripheral terminations.

Many other forms of neuralgia can be relieved by this simple method such as facial neuralgia, intercostal neuralgia, lumbago, &c.

AFTER a squabble extending over six months, the Aberystwyth Guardians have agreed to increase the salary of Dr. Bonsall from £30 to £45, as house-surgeon. Left to their own resources, boycotted by the local medical men, and finding no sympathy from the Local Government Board, the guardians recently gave a committee power to appoint Dr. Bonsall at the advanced sum, provided all posts were amalgamated.

INGUINAL HERNIA IN CHILDREN.*

By ROBT. CAMPBELL, M.B., M.CH.,
F.R.C.S. ENG.

THE author's paper was founded on an analysis of three hundred and five operations for the radical cure of hernia in children. He said that it was generally admitted that treatment by trusses was uncertain in its results, prolonged and irksome to the patient; whereas by operation a permanent and complete cure could be obtained within a fortnight. The great advantages of operative treatment being admitted, he said the question then arose, "At what age should the operation be performed?" He thought the only logical answer to this was, "As soon as the patient is presented for treatment, provided the general state of health be satisfactory." Some surgeons who had published articles recently on the subject had advocated treatment by trusses until the age of three or four years. He quoted statistics to show that 34 per cent. of his cases were operated on under six months; 44 per cent. under one year; and 77 per cent. under three years. He thought that the danger of sepsis in infants had been greatly exaggerated. Only two out of 305 cases had suppurated. He also called attention to the nature of the sac. In not more than 5 per cent. of the cases did it communicate with the tunica vaginalis testis. In other words, the common hernia of children was a hernia into a patent funicular process, which was, of course, as much entitled to be described as a congenital hernia as that in which the sac and tunica vaginalis were continuous. In referring to the contents of the sac he said that the frequency with which the cæcum and vermiform appendix descended in children was remarkable. He mentioned two cases in which the appendix was found adherent at its tip to the bottom of the sac; and another case in which a large Meckel's diverticulum was in the same condition. Strangulation was not frequent or acute in children. He had operated on sixteen cases, most of them were under one year of age, two being twenty-one and twenty-four days old. In one case the ovary and Fallopian tubes were found strangulated and gangrenous in the lower part of the sac, while the bladder and uterus were lying intact in the upper part. His experience of ovarian hernia had led to the following conclusions:—(1) That the operation in the abdominal wall is larger, rounder and nearer middle line than in intestinal herniæ; (2) that strangulation is due to twisting of the broad ligament, and not to constriction by neck of sac; (3) that the ovary involved tends to become enlarged and cystic; (4) that strangulation in these cases is common.

As regards after treatment, his usual plan is to remove stitches on fifth day, and paint wound with collodion; the patient, if under two years, is sent home on sixth day; if over two years, he is kept until ninth day. His own experience is that the operation is practically free from risk. The mortality should certainly not exceed 3 per cent. Radical cure of hernia in children might, therefore, as regards risk, be classified with many so-called minor operations.

* Abstract of paper read before the Society for the Study of Disease in Children, April 20th, 1906.

CLINICAL RECORDS.**REMOVAL OF A LARGE ADENO-CARCINOMATOUS TUMOUR FROM AN ELDERLY UNMARRIED PATIENT.***

By H. MACNAUGHTON-JONES, M.D.

IN this case a large adeno-carcinomatous tumour was removed from an unmarried patient, æt. 56, who had suffered for years from disorders of menstruation. The abdomen became greatly distended after a fall in December, 1905, and since then she suffered pain. A large quantity of ascitic fluid having been evacuated, two ovarian tumours of considerable size were found. The left was larger, more solid and multilocular, while the right was about the size of a small cocoon, the contents fluid, and its wall was thin. It had no appearance of malignancy. Subsequently, however, on careful examination of the wall the pathologist found that it contained spheroidal cells of the carcinomatous type. These tumours of an adeno-serous and adeno-mucin type were of considerable interest in regard to prognosis. Professor Hans Schroeder has written a monograph on the subject and shown, with Pfannenstiel and others, that those tumours in which the contents were serous were of a benign nature, whereas those containing mucin had a greater tendency to malignancy and to metastases. Schroeder had published a most interesting case verifying this conclusion, and other similar cases had been recorded. He showed, in this connection, a tumour which he had removed, in which the omentum was completely plastered over the surface of the tumour, so that he had to remove a large portion of it. At the time of operation there was little doubt in his mind that the tumour was malignant. There were some small metastatic deposits on the omentum, and on the pelvic ligaments, but the microscope did not reveal malignancy. The patient recovered from the operation, but subsequently suffering from uncontrollable vomiting, he re-opened the abdomen and removed some omental adhesions, after which she made an apparently good recovery. There was, however, a recurrence of growth, and she died within six months of the operation from metastatic growths.

There were other very interesting points connected with these cases in regard to a malignant growth appearing in the abdominal wound. In benign cases it would appear that the less the peritoneum was injured the better. In some instances the peritoneum so adhered to the surface of the cyst wall as to form a capsule for the tumour.

Professor Hans Schroeder's paper was one of considerable interest, and was well worthy of perusal. The differentiation of these various forms of adenoma in relation to transitional changes of a malignant character, was of the greatest interest and well worthy of further investigation.

SPINDLE-CELL SARCOMA OF LEFT OVARY.

By BOWREMAN JESSETT, F.R.C.S.,
Surgeon to Brompton Cancer Hospital, London, &c.

THE patient, A. H., æt. 50, was admitted into the Cancer Hospital for an abdominal tumour on March 5th, 1906.

She first noticed pain of a stabbing character in the hypogastric region, and soon after this found that her abdomen was getting larger. The pain increased in severity, especially during the last month, and the abdominal swelling had rapidly increased, and on admission caused shortness of breath on exertion. Micturition normal. Bowels constipated. Climacteric occurred six months ago. Prior to this menstruation was not excessive.

Objective Examination.—Abdomen prominent, especially in lower part. It feels tense and in hypogastric

* Specimen shown at the British Gynecological Society, April 9th 1906.

and left iliac regions a solid hard tumour can be felt on dipping hand into abdomen and displacing fluid in front of it. Side to side thrill was obtained. Percussion—Dulness in hypogastric and lower umbilical areas extending into left lumbar region. Above the umbilicus is intestinal resonance; also to the right of mid-line. No change occurs on rolling patient on her side. The fluid does therefore, not appear to be free in the abdomen. Liver not felt. By rectum tumour cannot be felt in pelvis. Vaginal examination not made.

Operation took place on March 20th, 1906.—Median Laparotomy—A large amount of dark, ascitic fluid escaped. Parietal and visceral peritoneum were found very congested and reddened. All the fluid was soaked up with sponges and then a solid left ovarian tumour of the size of a fetal head was drawn up out of the wound. The posterior part was necrotic, and it appeared as if a cystic portion might have ruptured and set up the peritonitis. The pedicle was found twisted at least twice. The broad ligament was pierced by a silk ligature, tied, and the tumour removed. The stump of the pedicle was then oversewn with fine catgut. The right ovary was found fibrous, but was not removed. No secondary deposits of growth were seen. The abdominal wound was sewn up in layers: (1) peritoneum, catgut; (2) aponeurosis and muscle, catgut; (3) skin and fascia, salmon gut and fine silk.

On March 30th the stitches were removed, leaving a healthy scar.

On April 2nd, 1906, patient vomited. Wound now well. Bowels not moved for two days. Colocynth and hyoscyamus pill ordered.

On April 3rd, patient well; bowels had been moved. On April 4th, scar perfect. Patient well.

Pathologist's Report.—The morbid changes are confined to the stroma, and show all the characters of a spindle-cell sarcoma. There are large areas of necroses and hæmorrhage, and the tissues show active growth.

THE OUT-PATIENTS' ROOM.

METROPOLITAN HOSPITAL, KINGSLAND ROAD.
SEROUS APOPLEXY.

By LEONARD WILLIAMS, M.D., M.R.C.P.

AMONG the out-patients was a woman about whose case Dr. Williams made the following remarks:—This woman, æt. 45, was an in-patient here four years ago, when she had both ovaries removed. She nevertheless continued to menstruate until last November. Since then she has had a great deal of trouble with the blushings and perspirations which so frequently afflict women at the menopause. She comes to us to-day because last week she had what she calls a fit. She has had similar attacks before, the first being about sixteen years ago, while she was pregnant. Since that time she has had about twelve, including last week's attack, the majority of which have been since her double ovariectomy four years ago. All the "fits" have been substantially of the same character. She does not lose consciousness completely, she does not bite her tongue or void her urine, and she is not convulsed. Each attack is, however, characterised by giddiness and nausea, by blindness on the right side, by pins and needles in the right half of the tongue, in the right arm and leg, and is accompanied by difficulty of speech. The duration is from ten minutes to a quarter of an hour, and every attack has been followed by a very severe headache.

Now, we have to consider what it is that gives rise to these fits or seizures. The problem is not by any means a simple one. We may, however, at once exclude any so-called functional, neurotic or hysterical element. Such an element is by no means rare in those who have had their ovaries interfered with, and in women at or about the menopause it is exceedingly common. It is only necessary to look at this woman and to hear her tell her story, to appreciate

the fact that she is not the stuff of which hysterics are made. She is a straight-forward, common-sensical hard-working woman who has always made light of her fits; and she tells us that she would not herself have troubled about the one which occurred last week, but her husband, who had never previously witnessed a seizure, was so alarmed at her condition during and after this one that he insisted upon her seeking advice. That she has never lost consciousness, bitten her tongue, or voided her urine in her fits enables us with some confidence to exclude epilepsy as their cause. Epilepsy, especially in the form of petit-mal, may of course occur without any of these features, but there is nothing in the concomitant symptoms to suggest its presence, so we may safely leave it out of consideration. Have, then, these attacks been due to apoplexy? Before answering such a question we must understand what we mean by apoplexy. Loosely, apoplexy is spoken of as any condition which may give rise to a hemiplegia or a hemiparesis. Now such conditions are recognised as three in number, namely, cerebral hæmorrhage, cerebral thrombosis and cerebral embolism. Of these three we may dismiss the first and third for the reason that it is practically impossible for her to have had twelve attacks of either without there being now some definite signs of their occurrence. For, as you have seen, the examination for physical signs in her nervous system has been entirely negative. She presents nothing of any kind which the most captious critic would venture to describe as abnormal. Moreover, against hæmorrhage we can urge the invariable retention of consciousness, and against embolism the complete absence of any cardiac difficulty. Can it, then, be thrombosis which is causing her attacks? We have only to think of her age—45 years—to look at her sturdy, well-nourished frame, and to satisfy ourselves of the vigour of her heart's action to answer such a question in the negative. The existence of any suspicion of syphilis might well give us pause in this matter, but there is no such suspicion, such evidence as is available being, indeed, all in the other direction.

Apoplexy, therefore, as the term is now commonly used is evidently not the cause of these attacks. But there is another kind of apoplexy, a kind which was much in the minds and frequently on the lips of our forefathers, but which a too exclusive attention to *post-mortem* findings has almost driven from our nomenclature. I mean serous apoplexy. That some such condition has a very real existence has been an article of faith with me for some time, and this patient presents a very good example of the operation of this factor. For serous apoplexy means the increase of pressure inside the cranium. It may not be a strictly correct term, but it is one which conveys with considerable force and sufficient accuracy, the idea that the inter-cranial vaso-motor action is disturbed or deranged, to the extent of causing or permitting undue pressure upon the important structures grouped in or about the internal capsule. I am not now prepared to dogmatise about the exact nature of this disturbance, but there is good ground for believing that it is associated with high blood pressure. We know that high blood pressure may cause an œdema or "serous apoplexy" in other parts, and there seems to be no reason why it should not produce an over-fulness of the cerebral ventricles. Why the effects of such an over-fulness should show themselves more on one side of the brain than on the other, it is not easy to say, but we may suppose, I presume, that the vessels on the left side, being those which supply the more active groups of cells, are probably larger, and that their dilatation or contraction would therefore produce a greater disturbance than alterations of calibre in the corresponding vessels on the other side.

The lesson, then, that we may learn from this woman's case seems to be this. There are undoubtedly a large number of people who come to us with very definite histories of hemiplegia; so definite and circumstantial that it is impossible to believe that there had been

any mistake about a correct diagnosis at the time of the occurrence of the symptoms. Nevertheless, when we come to examine these people for definite signs, we find no rigidity, no excess of knee jerk, no ankle clonus, and no extensor response. It is hardly conceivable that if the hemiplegia had been due to a hæmorrhage, causing destruction of brain substance, or to a thrombosis or an embolus, leading to softening of the brain substance, that there would not be some descending degeneration leading to definite physical signs.

It is a common experience with all of us to come across such cases, and the facts connected with this woman's seizures suggest to my mind very strongly that not only she, but various other people, who have attacks of hemiplegia or hemiparesis may be the subjects of "serous apoplexy," due to an increase of blood pressure within the cranium.

OPERATING THEATRES.

TOTTENHAM HOSPITAL.

CASE OF INTUSSUSCEPTION.—Mr. H. W. CARSON operated on a male child, æt. 3 months, who had been brought to the hospital with the following history:—The child had been in perfect health until three days before admission, when it was apparently seized with severe abdominal pain; vomiting occurred, but was not repeated; the boy continued in pain and on the day following the seizure passed a motion consisting chiefly of blood-stained mucus. On admission the child was seen to be well-nourished, but had a somewhat pinched expression, with sunken eyes. The abdomen was slightly distended and resistant to examination, so that no tumour could be felt. Rectal examination showed relaxed sphincter, and within an inch of the internal sphincter the apex of an intussusception could be plainly felt. Immediate operation was decided upon, and under the anæsthetic a long firm mass could be felt in the situation of the descending colon. The abdomen was opened, and the intussusception reduced by manipulation. The operation was completed in twelve minutes, in spite of some difficulty in starting the reduction owing to the position of the apex of the intussusception which was deep down in the pelvis, and in spite of some slight difficulty in reducing the last half inch. Mr. Carson said that it was now generally recognised that the best treatment for intussusception was immediate laparotomy, as attempts at reduction by hydrostatic pressure frequently failed, owing to the adhesions between the serous coats of the invaginating bowel as the result of local inflammation; these adhesions always occurred at the apex of the intussusception, and this, he pointed out, leads to the difficulty frequently found in reducing the last half inch. It was obvious, he thought, that if the abdomen were not opened the surgeon might easily imagine that reduction had been complete, seeing that the small portion of unreduced gut would not give rise to a palpable tumour. He pointed out that success in these operations depended on certain factors:—(1) *Duration of the intussusception*: the earlier a case of intussusception came under treatment the better the prognosis, other things being equal, as intestinal obstruction is very badly borne by infants; (2) *the condition of the intussuscepted gut*: with few exceptions, any condition requiring prolonged operative measures such as resection of gut was fatal to success; (3) *rapid operating*: this he considered was a most important point and in an uncomplicated case the operation from start to finish should certainly not take longer than a quarter of an hour, as babies are notoriously bad subjects for operation, owing to their

susceptibility to shock; (4) *skilful anæsthesisation*: upon this depends very largely the ability of the surgeon to complete the operation rapidly, as it is most important that there should be no rigidity of the abdominal wall, which would perhaps lead to protrusion of gut and consequent difficulty of manipulation. In discussing the details of the operation Mr. Carson pointed out that fortunately intestinal distension was not a marked feature in these cases, so that usually there was no difficulty in locating the intussusception after the abdomen had been opened. The most advanced part of the intussusception should be drawn into the wound if possible, as this rendered manipulation more easy. Reduction of the intussusception was brought about by pressure on the apex of the invaginated part which was thus pushed backwards; it was not wise, he said, to pull upon the intestine above the intussusception. Attention must be paid to the condition of the peritoneal coat in the ensheathing layer which may give way if there is much tension during reduction.

The child passed a motion containing blood soon after the operation; from that point recovery was uninterrupted, and the patient was sent out of the hospital in a fortnight.

FRENCH HOSPITAL AND DISPENSARY.

EXTENSIVE SYPHILITIC CONDYLOMATA.—Mr. DE MERIC operated on a girl, æt. 19, who had been admitted three weeks previously in a pitiable condition. The whole of the pubes, the external or muco-cutaneous parts of the labia majora, the contiguous portions of the thighs, the anal region and the internal surfaces of the buttocks were covered with condylomata; nearly all of the papulous tumours were exuding a thin discharge and many of them were conglomerated. A very foetid condition had thus been established, which had probably been much increased by the patient's neglect of herself. The girl could hardly walk, and every movement even in bed caused her very great pain. She was weakly and anæmic, the weakness being evidently the result of the constant irritation and pain set up by the disease. She had syphilitic teeth; but was well developed for her age. There was a nebulous history of syphilis having been contracted some three or four months previously. There was no sign of any secondary eruption, nor of "plaques muqueuses," in the mouth. The glands in the left groin were slightly enlarged. No loss of hair. For some days after admission the odour set up by the exudation from the diseased part was very disagreeable, but by means of constant hip baths containing a weak solution of carbolic acid, by keeping the parts dressed with black wash and occasionally with red wash and well dusted after the baths with a powder of iodoform and oxide of zinc the local condition was very much ameliorated, but the condylomata still remained in the same state, and, as far as could be ascertained by examination (which was rendered extremely difficult by the pain it caused), seemed inclined to spread, in spite, too, of anti-syphilitic internal treatment. It was therefore decided to endeavour to get rid of them by operation. The patient was anæsthetised and placed in the lithotomy position, an extra support being placed under the buttocks so as to raise them thoroughly. With scissors, knife and scraper Mr. de Méric removed the whole crop of condylomata, having literally to shave them off where he could not get at them with the scissors. They extended above the pubes on to the abdomen, the pudendal hairs having to be shaved during the operation as it was not possible to do so before. At the side of the right labium majus

in the fold of skin two extensive and deep ulcerations were found after removing the condylomata in this situation, the ulcers being about the size of a penny and a halfpenny respectively. To these Mr. de Méric applied nitrate of silver freely. The whole extensive raw surface was thickly powdered with oxide of zinc and iodoform, and dressings applied. Mr. de Méric said that he had never before seen a case in which condylomata had invaded such a large surface, the only one at all approaching it being that of a woman on whom his father, Victor de Méric, performed a similar operation many years ago. He pointed out that neglect and dirt were generally responsible for such severe cases. The two extensive ulcerations he had found were caused, he considered, by several of the condylomata becoming confluent, because, as the roots are on a level with the skin, these papular erosive syphilides do not extend into the derma, but grow outwards, but when several of them coalesce, a deep ulceration may result. He commented on the very little effect that ordinary anti-syphilitic treatment had on these growths. Neither mercury nor iodide of potassium seems to produce the slightest effect on them. On the other hand, when they have not much extended, they are easily amenable to external remedies, but in a case like the present one, and especially in a hospital patient, the only way was to perform the small operation he had just done. He said that as the raw surface was so great he did not feel justified in applying nitric acid as was always his custom when only a few condylomata have been removed.

Three weeks after operation the wounds had all healed up, the two ulcerations having granulated healthily; the girl can walk without pain; there is no scarring.

SPECIAL ARTICLE.

UNIVERSITY EDUCATION IN IRELAND.

FROM A CORRESPONDENT.

AN article from a correspondent of this journal (March 21st), interesting in itself, is, perhaps, more so as raising the question as to the interest Irish medical men take in university education. Judging by expression of opinion coming from them, it is apparently not very great, and for reasons, some on the surface and some to be looked for as truth at the bottom of a well. Only a small fraction of them hold Oxford, Cambridge or Dublin degrees, and, to speak the truth, the majority probably set only the value of social distinction on what they lack. They hold, and not without reason, that, apart from that adventitious value, they lose nothing, and perhaps gain something, by their studies having been pursued outside of the historical universities and their atmosphere.

The writer of the article referred to asks, What would be thought of an Archbishop of Canterbury if he had criticised the Oxford Medical School with the spirit and purpose of his Grace of Dublin in dealing with the Trinity College School. What would be thought by medical men would be, that he would do so under the impression that medical education should be controlled by ecclesiastics. And what informed medical men must know is, that Anglican ecclesiastics did actually aim at controlling such education, dictating what it should be in detail, and that such liberty of teaching there may be now is the result of a struggle by medical men against them, and particularly in Oxford. The spirit and purpose of his Grace of Dublin is exactly the spirit and purpose which medical men have had to meet more particularly as animating Oxford ecclesiastics and the university they had under their thumb.

In his evidence before a Royal Commission on

University Education, Bishop O'Dwyer is reported as saying that Huxley might teach biology all his life, but that if, under cover of teaching biology, he propagated among his students the opinions given in his Lay Sermons he should be stopped.

But Huxley was stopped, or a serious attempt made to stop him when he taught purely technical biology long before he was tempted or forced into the field of theological controversy. It was probably because of the attempt to stop him that he entered the alien field. He taught comparative anatomy, including embryology on the basis of the doctrine of evolution as a working hypothesis giving coherence to an otherwise incoherent and inexplicable mass of facts. It is matter of history that in doing so he found himself opposed by a body of public opinion sedulously fostered by university men, whose competence to criticise vertebrate morphology was vouched for in the public mind alone by the M.A.'s and D.D.'s appended to their names. He was far too good a teacher to drag irrelevant matter into a technical science, and he was far too good a logician not to know how to deal with irrelevant matter when he found it forced into his science with would-be deadly effect. As a logician he dealt with the intrusive matter, and by doing so, carried the war into the enemy's camp; it was, anyhow, the man's nature to do so. It was a case of necessity; sermons, tracts, ponderous tomes by the hundred were aimed at discrediting evolution not by criticism in the true sense, but by appeal to prescriptive ideas and traditional prejudices. It is idle to think that what is now understood as biology would have come into existence if what Huxley called ecclesiasticism had its way. That ecclesiasticism blocked the science as Huxley understood it, and all there was left him to do was to deal with what would not give his science the right to exist and develop on its own lines.

It is matter of regret that he wasted his abilities in going over what theologians themselves have gone over *ad nauseam*. If, however, there were not Huxleys to raid on due occasion on ecclesiastical property, the domain of science would be very small and singularly barren.

If now Prof. Gaskell and a dozen other anatomists are free to build up a concept of the genetic formation of the human body without ecclesiastical interference, Huxley and some others have to be thanked for it. The lesson, however, remains that the ecclesiastically-controlled universities trained and inspired the men who challenged Huxley on his own ground, only to be challenged by him on their ground. It is evident that the question is not of any particular type of Ecclesiasticism, Roman Catholic, Anglican, or Presbyterian. Darwin and Huxley were assailed from every point of the ecclesiastical compass by representatives of every denomination. That, of course, in an age of religious toleration could be passed over; what could not and cannot be passed over is that the sciences in which medical men are peculiarly interested should be asphyxiated in the atmosphere of Oxford ecclesiasticism in which Huxley found them. What medical man would submit to have views, however problematical, of pathology as depending on the assumption of functionless or vestigial cell-groups prohibited expression by ecclesiastics? If vertebrate morphology points, however obscurely, to a genetic evolution of the human body, are we to allow the line of inquiry to be discountenanced because disagreeable to the ecclesiastical mind?

It ought to be regarded as an open question whether there is any advantage gained by grouping schools of medicine, law and engineering together in a university. On the face of it, there is absurdity in a university practically devoted to giving lads a rather superficial knowledge of mathematics, Greek and Latin, and governed to that end, undertaking medical education. The thing places such education far too much under the control and influence of outsiders, and thereby leaves the door open for ecclesiastical interference. Medical education should be left in the hands of the

medical profession. If the public or the State claim an interest in it, the claim is not met by leaving it to the governing bodies, such as they are, of the universities. As so left, individuals like Huxley have had the task of saving its freedom, of really emancipating it from the influences dominating the universities, imposed on them, and have had to discharge it by means medical men have little sympathy with. Most of us would agree with Bishop O'Dwyer in saying that Huxley ought not to have attacked religious opinions under cover of teaching biology—that is, if he ever did

so. I believe, however, that the theological blizzard which blew so hard from Oxford justified his action as one of necessity, and that it was altogether direct.

Medical men are well inclined enough to keep within their own province, but their province must be secure to them. The better their knowledge of the historical teaching universities is the clearer, probably, it will appear to them that control of medical education by the profession requires not association with, but complete dissociation from, these institutions.

TRANSACTIONS OF SOCIETIES.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD THURSDAY, MAY 4TH, 1906.

Mr. PRIESTLY SMITH, F.R.C.S., President, in the Chair.

MR. MACKENZIE DAVIDSON read a paper on RADIUM IN THE TREATMENT OF RODENT ULCER. He gave a short description of radium and its source, and then gave details of how he applied it, and the results he had obtained in the somewhat large number of cases which he had had under his care. As a rule, he found it unnecessary to apply the radium very frequently. In many cases cure had been effected with one or two applications with several weeks' interval between the applications. In other cases more frequent application was necessary. The radial activity of different specimens of radium varied, but it was possible by means of an electroscope to measure this. He preferred to use it when encased in a sealed glass tube, for the glass shut off some of the harmful rays which would burn the skin, and which were of no use for destroying the rodent cells. The power of radium was for practical purposes a fixed quantity in any one specimen, so that the dose given was known absolutely; in this way it differed considerably from the X-rays, which were not constant, but depended upon a variety of circumstances.

Mr. RANSOM PICKARD (Exeter) described a case of Implantation Cyst containing wood fibres. The patient was a girl *æt.* 14, and the tumour had been noticed for nine years. It was 3 mm. in diameter, and was situated below the pupil. The growth was removed, and its base was found to be composed of granulation tissue containing three wood fibres of coniferous origin. The tumour consisted of epithelial cells, and contained several cysts, some of which were formed by degeneration of the cells, and others by the formation of fissures. There was no history of injury to the eye; the cornea was quite normal; but in all probability the cornea had become perforated ten years ago by a fine splinter, for at that time she fell and struck her nose against a table.

Messrs. TREACHER COLLINS and JOHNSON TAYLOR (Norwich) described a case in which there was a cystic swelling occupying the position of the left eye, and apparently mainly formed by a bulging forward of the conjunctiva of the upper lid. It was present at birth, and had steadily increased since.

Mr. Johnson Taylor first saw the child when three weeks old. He then tapped the cyst with a fine trochar and canula; it refilled the following day. When next seen, about a year later, it had increased considerably in size in all dimensions, it stood out $2\frac{1}{2}$ inches from the orbital rim and gave a most unsightly appearance. Blood and discharge had also been exuding from it for two months. Under a general anæsthetic Mr. Johnson Taylor removed it entirely, and handed it over to Mr. Treacher Collins for examination.

The examination showed that the cyst was due to an enormous distention of the whole globe, the sclerotic forming its outer wall. The inner coat corresponded to the retina, but in no place did that portion, derived from the secondary optic vesicle, lie in contact with

that developed from the outer layer. The anterior portion of the cyst was lined by the former, and the posterior part by the latter. The cavity of the cyst was composed of a space between these two layers, the cavity of the primary optic vesicle.

The explanation of the formation of the cyst was apparently the imperfect involution of the primary optic vesicle which forms the secondary optic vesicle. There had been some attempt at involution both anteriorly and below. Anteriorly the inner wall of the cyst was prolonged backwards in a fold, at the bottom of which was a rudimentary lens, so that at one stage there must have been some downgrowth of surface epiblast. Below was a mass of a typically developed vitreous, and the expansion of the cyst below must have been checked by this upgrowth of mesoblast, hence the chief distention upwards into the upper eyelid. As the whole of that portion of the retina which normally forms the inner layers was in the anterior part of the cyst, it is not surprising that no optic nerve was developed. The lens showed a defect in its posterior capsule, and through this gap mesoblastic tissue had extended forwards, and become mixed with the lens fibres. A nodule of hyaline cartilage was found in the sclerotic at the posterior part of the specimen.

THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD APRIL 20TH, 1906.

Dr. J. PORTER PARKINSON in the Chair.

MR. W. MILNER BURGESS showed a case of "Psoriasis Guttata" in a healthy-looking boy, *æt.* 6 $\frac{1}{2}$. The spots commenced when the child was *æt.* 5, few in number at first; they are best marked on the chest, abdomen, anterior, and inner surface of the thighs and back.

Dr. CAUTLEY exhibited a case of "Atelectasis" of both upper lobes. Female, *æt.* 31 days, born in full time. No history of cyanosis at birth or attacks of lividity. Cough for two weeks. Weight, 6lbs. 12 ozs. Temperature a little irregular. The note is impaired over both upper lobes and the air entry is very feeble. Good resonance over the rest of the lungs. Occasionally goes very blue, chiefly after coughing.

Dr. CAUTLEY exhibited a case of "Hæmatemesis and Melaena" due to gastric ulcer. A girl, *æt.* 5. Quite well until March 17th. She then vomited about a pint of dark clotted blood and shortly afterwards passed a tarry stool. Next day she again vomited blood, about half a pint, brighter in colour, containing clots. Next day passed a black stool. No history of pain after food. Anæmic on admission. Spleen and liver a little enlarged. Uninterrupted recovery. Gain of 28 ozs. in last two weeks. Blood count.—Red cells 3,512,000; white cells, 28,250 of which 63 per cent. were polymorphonuclear leucocytes.

Dr. CAUTLEY exhibited a case of "Sarcoma of the Lung." Male, *æt.* 10. Early in January had an attack of (?) pneumonia of right lower lobe. Ailing since. February 12th—Physical signs of pleurisy at

right base. February 16th.—The screen showed a horizontal shadow on the right side and no movement of the right half of the diaphragm. February 23rd.—Explored under an anæsthetic, but no pus found. March 6th.—Breath sounds feeble and note still impaired at right base. March 16th.—Has gained about 4lbs. in weight. Still dulness, deficient air entry, and diminished vocal vibrations over right lower lobe. Signs of a cavity subjacent to right nipple. March 23rd.—More extensive signs of breaking down of the lung, but no expectoration; very deficient movement and air entry. March 31st.—Signs of a large cavity over right lower lobe behind. April 17th.—The signs of excavation have cleared up; dulness is more extensive and extends on to the sternum; breath sounds are weak from the third to the fifth rib, and almost absent below that in front. Dulness, feeble breath sounds, feeble bronchial breathing, and bronchophony. For about ten days he has had some vomiting, cough, and slight hæmoptysis. The heart does not appear much displaced. Practically free from fever for seven weeks.

Dr. BEATTY (Belfast) read notes of a case of "Chloroma," in a young child for Dr. McCaw (Belfast). F. J. K., æt. 18 months, was admitted to Belfast Hospital for Sick Children on October 30th, 1905, with a history of having been ill for three weeks. *On admission.*—Child seems well developed and well nourished. Is markedly anæmic, and has a peculiar froglike appearance due to proptosis and to swelling and echymosis of eyelids, and also to swellings about the size of a tangerine orange in each temporal fossa. The proptosis and swelling are greater on the right side than on the left. The swellings are hard, dark-coloured, and give no evidence of fluid contents. A tumour the size of an egg is situated over the upper part of the sternum, similar to those in the temporal fossa. The glands in the groin are swollen, hard, and black coloured, but not tender. The axillary glands are slightly enlarged. The lower end of the left femur is swollen and very tender at movement. The gums are not healthy, but not swollen or spongy. The heart and lungs are healthy, no enlargement of the liver and spleen is present. The urine is normal and the bowels are open. The temperature is 99.4° F. *Progress.*—The child got gradually worse and died three days later. No *post-mortem* examination could be obtained. *Blood examination* by Dr. Beatty.—Red, 1,150,000 per c.m.; whites, 16,000 per c.m.; H.C., 34 per cent. *Differential Count.*—P.M.M.'s, 28.8; S.L., 59; L.L., 8.6; T. L., 1.2; Myelocytes, 2.6; eosinophiles, 0; normoblast equalled 5.4; megaloblasts, 0.6. Marked variation in size of red cells, varying from 5u—11u. Two-fifths were over the average size, and some were undoubtedly megalocytes. Many of the normoblasts were in mitotic division.

Mr. ROBERT CAMPBELL (Belfast) read a paper on "Inguinal Hernia in Children, Giving an Analysis of 305 operations for Radical Cure." An abstract of this paper will be found on page 498.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, APRIL 26TH, 1906.

The President, FRANK T. PAUL, F.R.C.S., in the Chair.

Dr. J. LLOYD ROBERTS read a note on "Ankylostomiasis," based upon the case of an English sailor, recently under his care at the Royal Southern Hospital. He described the parasite which was the cause of the disease, the mode of infection, the symptoms, the blood changes and the treatment. He also showed specimens of the adult worms, and lantern slides of the worms and of fæces containing ova.

UNUSUAL CASES OF GALLSTONES.

Mr. RUSHTON PARKER related two very different cases of gallstones. (1) A woman, æt. 45, suffered from pain, vomiting and dyspeptic symptoms, suggestive of gastric ulcer. An exploration made in the middle line of the epigastrium revealed adhesions between the pylorus and the liver; when these were

freed a gallstone was felt in the gall-bladder. The stone, of the size of a small marble, was removed and the gall-bladder sewn up at once. The patient went home in a few weeks apparently cured. The patient returned saying that the immunity from symptoms had only lasted two months. On March 8th, 1906, Mr. Parker opened the original scar again, and extended the wound downwards to give easy access to the biliary passages. A stone in the gall-bladder was removed, the cystic duct tied and cut and the gall-bladder removed. Another stone was found impacted in its neck. The patient made a complete recovery in five weeks. (2) A stout and apparently vigorous woman æt. 71, was admitted on December 30th, 1905, with symptoms of intestinal obstruction of three days' duration. Three similar attacks in two years had yielded to copious enemata which brought away large faecal accumulations. Jaundice was set up in each attack after twenty-four hours. A small slack umbilical hernia was apparently not involved in the symptoms. The abdomen was opened through the hernia by a transverse incision. General peritonitis with adhesive yellow lymph and inflammatory thickening of several feet of the small intestine. A hard object felt in the gut one foot above the ileo-cæcal valve was found on removal through an incision to be a gall-stone 1½ inches long and ½ inch thick. The intestinal incision was sewn up and the abdomen closed. The patient died three hours later. At the necropsy the liver was found enlarged and fatty, the gall-bladder exceedingly small but filled with a second calculus less than half the size of the one that had escaped. A perforation in the gall-bladder led to a space under the liver and thence into the duodenum. This suppurating space was shut off from the peritoneum and did not account for the peritonitis. The latter more probably resulted from transudation of septic intestinal contents during the impaction of the larger calculus in various parts of the small intestine. The state of the patient's viscera, her age, and the duration of the disease together completed the hazard of the situation.

THE AFTER TREATMENT OF HERNIA IN CHILDREN.

Mr. R. C. DUN read a note on "The After Treatment of Cases of Radical Cure of Hernia in Infants and Young Children." The growing tendency to adopt early operative measures was commented on, and a comparison drawn between the results of operative treatment and those obtained by the use of trusses. The chief points in favour of early operation were the certainty of cure and the short duration of treatment. Many children apparently cured by trusses subsequently developed hernias in later life, and these recurrent ruptures were apt to be looked upon as acquired. The strongest evidence existed that the majority of cases of inguinal hernia occurring in adult life were of congenital origin. The simplicity and safety of operations for the cure of hernia in infants and young children were explained. Stress was laid upon the importance of obtaining primary union of the wound. The supposed difficulty of preventing contamination by the evacuations in children too young to have obtained control had up to the present stood in the way of a more universal recourse to early operation. The open method of after treatment devised and published by Stiles of Edinburgh had, after 15 months' trial, given thoroughly satisfactory results in Mr. Dun's hands. This method was described in detail. Its simplicity and the certainty with which it prevented soiling of the wound rendered it the best form of after treatment.

Mr. R. W. MURRAY read a paper on the ETIOLOGY AND TREATMENT OF OBLIQUE INGUINAL HERNIA.

He said that although the presence of an inguinal hernia must be due to some weakness of the structures through which the abdominal contents escape, the question yet to be answered was, "What are the chief factors which cause this weakness and so determine the descent of the bowel?" He did not agree with the generally accepted division of inguinal hernia into

Congenital and Acquired, and after pointing out the marked difference between a typically congenital and a typically acquired hernia said that the sac of an ordinary inguinal hernia at all periods of life closely resembled the former and bore little or no resemblance to the latter. He maintained that the main factors in the causation of oblique inguinal hernia at all ages were firstly the presence of a congenital or preformed sac and secondly want of strength in the muscles guarding the internal abdominal ring. Evidence derived from a study of comparative surgery, *post-mortem* observations and clinical experience were adduced in favour of this belief. As to treatment, Mr. Murray said the cure obtained by means of a truss must always be uncertain, for he did not believe that the funicular process ever became completely obliterated by this method. He strongly advocated operation during infancy, when a permanent cure could be assured. In operating he usually adopted the same method irrespective of the age of the patient. The essential points of the operation were that the inguinal canal was opened up and the sac excised after applying a ligature to it at the level of the internal abdominal ring. The divided aponeurosis of the external oblique was united by overlapping. In exceptionally large herniæ in adults he had obtained satisfactory results by inserting a rubber pad which rested on the Transversalis fasciæ beneath the internal oblique and Poupart's ligament. A hole in the pad transmitted the spermatic vessels and the cord.

The PRESIDENT thought the statement that all inguinal herniæ were due to the presence of a congenital sac was too sweeping.

Mr. RUSHTON PARKER thought that the terms congenital, infantile, and acquired should be abolished. He had advocated the early operation in infants more than eleven years ago. The sac should be obliterated but there was no need to remove it and there was no need to close the inguinal canal in children. He considered that the length of the mesentery was an important factor in the Etiology of hernia.

Mr. K. W. MONSARRAT said that Mr. Murray had added considerably to the already strong evidence in favour of the view that in the great majority of cases, at any rate, hernial protrusions took place into preformed sacs of congenital origin. He thought that all the evidence pointed to the importance of dealing in the most thorough manner with the sac in all operations, and to do this he considered that it was necessary to slit the external oblique from the external ring upwards to a greater or less extent in all cases. Bassini's operation had given excellent results in the hands of many surgeons; he thought its chief merit was the perfect access it gave to the neck of the sac. There was no doubt that in a considerable proportion of cases there was defective origin of the internal oblique from Poupart's ligament, a defect which had to be remedied by suture. Mr. Monsarrat left the cord undisturbed and sutured the internal oblique to Poupart's ligament in front of it and not behind it, considering that it was a mistake to bring the cord through the muscular layer immediately superficial to the internal ring. The recurrences that took place after Bassini's operation did so at this point—a fact which supported the view that the weak point in the several layers of the wound should not be super-imposed.

Mr. G. P. NEWBOLT considered that though the majority of cases of oblique inguinal hernia had a congenital origin yet there were undoubtedly cases in which the condition was acquired. The radical operation in infancy was practically always successful, but the mortality was a factor to be considered and was higher than that in adults.

Mr. DOUGLAS-CRAWFORD agreed with Mr. Murray that all oblique inguinal herniæ were probably due to persistence of a funicular process, this view being supported by four cases of hernia occurring in boys about æt. 17; the first appearance being associated

with strangulation, and at operation each was found to possess a patent processus vaginalis with an extremely narrow neck about one inch in length, which had produced the strangulation. He used a simple colodion protection in children, instead of a heavy dressing and spica bandage, which being difficult to keep dry increased the risk of suppuration.

Mr. G. G. Hamilton, Mr. Damer Harrison, and Mr. T. C. Littler Jones also took part in the discussion on Mr. R. C. Dun's note and Mr. R. W. Murray's paper.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

CLINICAL MEETING HELD AT MANCHESTER, APRIL 27TH, 1906.

MR. R. FAVELL (Sheffield), President, in the Chair.

DR. J. T. GEMMELL (Liverpool) showed—(1) A fibroma of the labium majus, as large as an orange, which had considerable diffuse extensions into the buttock and towards the inguinal ring. (2) A large cervical fibroid, whose central portion was undergoing degeneration closely simulating sarcomatous change. It was removed by enucleation by the abdominal route. An opening was then made into the vagina, and the bed of the tumour was packed with gauze. The peritoneum was then closed, the gauze being subsequently withdrawn per vaginam. (3) A fibroma of the ovary weighing 4 lbs., removed from a patient, æt. 47, who had had seven children and who menstruated regularly. The abdomen contained some ascitic fluid.

DR. LLOYD ROBERTS (Manchester) showed the uterus with the bladder, ureters, and kidneys, from a patient who died of cystitis and necrosis of the bladder wall, with rupture into the utero-vesical pouch. She was admitted when five months pregnant with a retroverted uterus. There had been dribbling for five days, and 8 ozs. of urine were withdrawn by catheter. The bladder was kept empty subsequently, but the patient died five days later, soon after rupture of the bladder was diagnosed.

DR. BLAIR BELL (Liverpool) showed light and useful retractors for pelvic surgery, the blades being of stiff wire and having large fenestræ.

DRS. H. BRIGGS and J. H. WILLETT described two cases of fibromyoma, in which operation was required for symptoms due to the spontaneous extrusion of fibroids into the uterine cavity. In each case the endometrium was found to be the seat of adenocarcinoma.

DR. A. STOKES (Liverpool) mentioned a case of Cæsarean section for contracted pelvis, in which the pulse suddenly rose to 160 at the end of the operation. The same evening the temperature was 103 and the pulse 140. No cause for these manifestations could be discovered, and the patient's condition became quite normal during the next six days.

DR. W. WALTER (Manchester) showed a specimen of pyosalpinx with removal of an adherent appendix. The use was complicated by a tubo-ovarian and pelvic abscess. Microscopic sections of tube and appendix were shown. The appendix was thickened and measured half an inch in diameter. The microscopic appearance showed the mucous membrane was not involved, the muscular coat was thickened, and signs of inflammation, especially in its outer layers, were evident. The chief change in the appendix was due to a deposit of new-formed tissue outside the muscular coat, which was very vascular and resembled granulation tissue. Dr. Walter thought that removal of the appendix in cases of inflammation of the appendages on the right side was occasionally necessary, but believed in the majority of cases the appendicitis was secondary to the salpingitis, and that unless the appendicitis was well marked the appendix need not be removed simply on account of slight adhesions that could be readily separated.

THERAPEUTICAL SOCIETY.

MEETING HELD IN THE APOTHECARIES' HALL (Blackfriars), TUESDAY, APRIL 24TH, 1906.
SIR LAUDER BRUNTON, BART., M.D., F.R.S., in the Chair.

DR. JAMES BURNET, of Edinburgh, read a paper on the

THERAPEUTIC ACTION OF THE IODIDES, showing that they are alteratives, which influence metabolism and secretion. They have long been used against syphilis and scrofula, and more recently for gout, rheumatism, aneurism, and arterio-sclerosis. They were formerly supposed to act by dilating the arterioles and diminishing the blood pressure but they have no effect on the blood pressure or pulse, though they promote the coagulation of the blood. The author has found iodipin, that is iodine with sesame oil, most effectual when injected under the skin, as it does not cause any gastric disturbance, and the iodine is slowly set free by oxidation. It relieves arterio-sclerosis by diminishing the uric acid dissolved in the blood, and thus relaxing arterioles, and relieves aneurism if syphilitic by removing pathological effusion and counteracting the poison. In angina pectoris it must be given in large doses—60 grains daily for months.

He considered it decidedly most useful in chronic pulmonary diseases, especially fibrosis and emphysema, relieving dyspnoea and liquefying the bronchial secretion, and it is best given in doses of 15 grains at bed-time. In bronchial asthma doses of 10 grains every two hours are very useful, either by relieving spasm or freeing the blood from uric acid. In syphilis it is most useful from its antitoxic powers and its eliminative action, particularly in affections of the nervous system and headache. In locomotor ataxy 120 grains have been given daily with the best effect. It has also been used in cases of intermittent fever, puerperal fever, and erysipelas with success. In chronic rheumatism, neuralgia, lumbago, and sciatica potassium iodide is often useful, probably by diminishing the uric acid dissolved in the blood. It is best combined with salicylic acid which eliminates this acid. In cases of effusion, especially from interstitial nephritis or cirrhosis iodides are often of service. In lead or mercurial poisoning they remove the metal from the tissues. In simple goitre they are of great service, if used early, but not in exophthalmic goitre. The iodide of sodium is less depressing than that of potassium, while iodipin, given by the mouth or hypodermically, should be kept in mind as a useful substitute for the iodide of potassium.

CENTRAL BOARD OF MIDWIVES.

MEETING HELD MAY 3RD, 1906.

The President, Dr. CHAMPNEYS, in the Chair.

MIDWIVES' QUALIFICATIONS.

A LETTER was read from the Privy Council, asking if the question of the Irish Maternity Hospitals could not be settled by altering Rule D2, which says:— . . . "must have nursed 20 lying-in women during the ten days following labour" to eight days.

DR. PARKER YOUNG said he would like to have all the hospitals reduced to eight days instead of ten, but

The PRESIDENT reminded him that the midwives were ignorant enough without having their practical work shortened. He added that the concession made to the Irish Maternity should not in any sense include all the Irish hospitals.

It was finally arranged to accede to the request of the Privy Council by adding the words:—"Except in specific cases where the less period has been sanctioned by the Board."

The PRESIDENT gave notice of an intention to send to the Privy Council, asking for liberty to restrict midwives putting anything save "certified midwife" after their names. Some of them wrote L.O.S. and C.M.B. and one of such had sent him a letter adding

"artificial feeding and delicate children a speciality." It was bad enough when doctors had a crowd of letters after their name, but for ignorant women it was simply absurd and misleading.

DR. PARKER YOUNG and all present agreed to the proposal, which was accordingly entered on the minutes.

The Clerk of the Privy Council also wrote asking that the injunctions on midwives to send for a doctor be made more stringent by substituting in Rule E 18, for "she must advise that the attendance of a registered medical practitioner is required," the words "she must advise that a registered medical practitioner be sent for."

This was accordingly done, and Rule F 2, deleted in accordance with an intimation that no power of suspension of midwives is in terms conferred upon the Board, the only mention of suspension in the Act being in Section 8 (3) which confers that power upon Local Supervising Authorities.

CORRESPONDENCE.**FROM OUR SPECIAL CORRESPONDENTS
ABROAD.
FRANCE.**

Paris, May 6th, 1906.]

EXTRACTION OF FOREIGN BODIES FROM THE EAR.

THERE is hardly a practitioner of some years' standing who has not met, one time or another, with cases of a foreign body penetrating into the ear. The patient is generally a child and the foreign body a bead, pebble, pea, haricot, etc. Attempts have already been made by the patient or the parents to extract the offending body, but have failed. At first sight the case appears simple, but successful extraction is a really delicate operation. An inexperienced practitioner should learn first what not to do; it is a safeguard against complications. When the operator, with a laudable desire, introduces blindly, without the aid of a mirror, instruments into the ear, he risks penetrating into an ear containing no foreign body, and wounding it by his manoeuvres; entering an empty ear, that is to say, from which the foreign body has been already removed; pushing the foreign body farther in. Frequently, by reason of the smooth surface of the object, the forceps cannot take a good hold on it; it slips and sinks more deeply into the canal. After another and more violent attempt at extraction, the foreign body becomes impacted. A series of accidents becomes possible: retention of purulent matter, if it previously existed (suppuration of the middle ear), traumatism of the auditory canal with consecutive lymphangitis, etc., penetrating wound in the tympanum, fracture of the small bones, facial paralysis.

The chief danger, says M. Laurens, is in the retention of pus and the cerebral or mastoid complications which might result. In one case of Dr. Consteau the labyrinth had to be trephined in a patient in whom a practitioner, in his efforts to extract a pebble from the ear, broke his curette. The first indication is to ascertain by means of the otoscope the presence of a foreign body, as well as its *nature*, for it might be animate or inanimate. In the former case the insect (larvæ, mosquitoes, flies, etc.) must be first killed by instilling glycerine or oil into the canal so as to prevent it from holding on to the walls.

(b). Its *consistence*.—If it is a soft body (haricot, pea) which has become swelled. In this case retraction is obtained by instilling proof spirit for a day or two before proceeding to its extraction.

(c). The situation it occupies in the canal.

(d). The condition of the walls of the canal. Frequently, and by reason of attempts at extraction, there exists considerable inflammation, the parts are red, inflamed, and ulcerated. In such a case, and if there exists no reason for immediate interference, the operator should wait until the inflammation has subsided.

Extraction.—No matter what may be the nature, consistence, situation, or form of foreign bodies in the

ear, the mode of procedure is the same, viz., injections first, instruments afterwards.

In the immense majority of cases, injections made with a large syringe, repeated three or four times and for several days, are sufficient. The liquid used should be warm water that has been boiled. The jet should be directed as much as possible between the wall of the canal and the foreign body. The liquid insinuates itself between these points, and passing behind pushes the object from within outwards. A quart or more of liquid should be used, and frequently, if the body is not impacted, it is expelled at the first sitting. Otherwise the injections are repeated the following day, and for several days if necessary. Success will eventually crown the efforts made.

Where the body is impacted, proof spirit should be instilled, to retract the walls of the canal, several times a day, and for several days, and finally the injection should be renewed. However, if, after a fair and patient trial of this simple treatment, no ground has been gained the removal of the foreign body must be effected by the aid of instruments. A description of this mode of extraction is found in every work on otology and need not be mentioned here.

PROLAPSUS OF THE RECTUM IN CHILDREN.

Prolapsus of the rectum in children, similar to hernia, only needs to be maintained after reduction for some time until the patient grows stronger.

Nevertheless, the affection is very serious; the patient suffers in his general condition, and the parents are weary of having to reduce it at every moment.

Various are the methods proposed against the affection, but one of the best seems to be that practised by Dr. Roux, of Lausanne; it consists in injecting into the ano-rectal sub-mucous membrane three or four syringes (hypodermic) of proof spirit. The inflammation set up produces proliferation of the cellular tissue, prevents sliding, and cures the prolapsus.

GERMANY.

Berlin, May 6th, 1906.

At the 35th meeting of the German Society for Surgery, the papers on "Military Surgery" occupied a prominent position. After one on "First Aid" by Hr. Zoega von Manteuffel, and one on "Fitness for Service after Wounds with Modern Firearms," by Hr. Schaefer, Hr. Goldammer related his experience in the

DRY TREATMENT OF WOUNDS

in the South-West African War. The care and transport of the wounded was very difficult. The field lazarettos in that dry and arid land could only be established where there was a plentiful supply of water, and the troops might be frequently days' marches from it. The search for the wounded and their removal by the lazaretto officials was not possible; this must be done by the soldiers themselves, who must search them out and send them off on the provision wagons. In this way weeks might elapse before the injured could get into hospital and change their clothes. First aid must therefore be limited to what was most necessary. An absolutely dry treatment was the only means by which a moderate success had been achieved. A first dressing could only be applied *lega artis* when strict asepsis was possible, otherwise only a protection in the form of iodoform gauze and fixing it on with adhesive plaster was allowable. The wound itself should not be explored. The minimal bleeding in consequence of small entrance and exit wounds admitted of this. Later, when the pads had dried, a bandage could be put on, and in the case of fractures a simple splint could be applied. Everything then remained untouched until a thoroughly suitable dressing could be put on. In this first needful dressing there could be no question of even the most elementary disinfection, frequently even the hands could not be cleansed through absence of water, and the dressing must be applied just as it was taken out of the pocket. Rubbing the hands with raw spirit of soap was useless, as with crawling about the hands only got the dirtier for it. Every bony injury must be fixed up simply and

as quickly as possible, either with splints or plaster of Paris. The good results obtained in fracture were due to this speedy fixing up. Fractures of the thigh healed up as quickly as subcutaneous fractures. Infection was generally absent in consequence of the early dressing, and the refraining from interference with the wound itself. In 103 gunshot injuries, with 30 fractures of bone, healing by first intention took place in 87 cases. In 13 suppuration took place, but 7 of these were not brought under treatment at once; 4 died, and 58 became fit for service again.

Hr. Bornhaupt spoke on

WOUNDS OF JOINTS.

He saw 2,265 cases of injury in the Red Cross Lazaretto. They were not recent injuries, as the transport of the wounded with their first aid dressings applied had lasted six days. Of the wounds, 157, or 7 per cent., were joint injuries. As regarded the joints implicated, there were 87 of the knee, 32 of the elbow-joint, 19 of the shoulder-joint, 10 of the ankle-joint, 6 of the hip, and 5 of the wrist. In 108 cases the wound was caused by "mantle" bullets, 39 by shrapnel shots, and in 10 by grenades. The projectile remained in the wound in 14 per cent. of the bullet cases, and in 69 per cent. of the shrapnel wounds. Suppuration very rarely followed a perforating bullet wound, a little more frequently a perforating shrapnel wound, but it took place in 50 per cent. of the cases in which the projectile was in the wound.

Thirty-seven of the cases were operated on. The operations on the knee-joint were 4 resections with 1 death, 6 arthrotomies with 1 death, 7 amputations with 3 deaths. From the speaker's experience he was in favour of conservative treatment.

Hr. Brentano spoke on

GUNSHOT WOUNDS OF BLOOD VESSELS.

Eight cases were seen in the Charbin Lazaretto. The wounds had one thing in common—the skin wound was already healed or nearly so when the patients were received into hospital. Of the eight cases, 7 were operated on. The eighth case was one of wound of the aorta that was discovered accidentally at the *post mortem* examination. The patient had survived the injury 70 days, and died in consequence of subsequent hæmorrhage, which, as far as could be ascertained, did not come from the aorta but from the liver (preparation shown). In the other cases the wound was opened up and the vessel resected after ligature above and below. The injury was a grazing one in 4 cases, and in 3 was a perforation. He considered the perforation wound to be less favourable as regarded spontaneous healing than the grazing injury, as in 2 of the latter cases the wound was found closed six days after the receipt of the wound. The closure had been brought about by the adjoining nerves and fasciæ along with the injured vessels being bound into a whole by plastic exudation. That the artery must have been injured in these cases was proved first by the direction of the wound, and, secondly, by enteric absence or weakening of the pulse on that side. Then there was the striking hardness of the wound track and disturbance in the region of the nerves affected. Operation was performed when it was feared that an aneurysm might form later on at the seat of injury, as was observed in the Boer War. In 3 cases so-called false aneurysms formed which were operated on eight, eleven, and fourteen days respectively after reception of injury.

A wound of the external iliac artery which had missed the accompanying vein had led to an aneurysm the size of an egg. This was extirpated 83 days after the injury was received, the vein being left.

An arterio-venous aneurysm caused by simultaneous perforation of the femoral artery and vein in Scarpa's triangle was resected nineteen days after the injury. (The preparations from six of the cases operated on were shown.)

DR. ABERCROMBIE, having resigned the Curatorship of the Museum of the Royal College of Physicians, London, Dr. W. H. Allchin, consulting physician to Westminster Hospital, has been elected to the post.

AUSTRIA.

Vienna, May 6th, 1906.

PROTAGON.

At the Gesellschaft, Stoerk gave the members a history of Liebreich's discovery in 1865 of an element which he isolated from the brain substance. Of its history we hear nothing until 1897, when Schmidt and Müller drew attention to the similarity between this and Virchow's myelin drops, which he obtained from sputa. Kayserling and Orgler about the same time obtained from the supra-renal bodies a pathological substance which they term "myelinogene necrobioso." More recently Löhlein has demonstrated that protagon is a pathological product of the kidney also, and met with in the cortical substance of the organ with a double refractive power. It is found in greatest quantity in nephritis, particularly in that form known as hæmatogenous nephritis, probably having an arterio-sclerotic or amyloid basis. The substance appears as a crystalline in small particles in the canaliculi with the epithelial of the protoplasm and easily detected by polarised light and its tinctorial property. It is somewhat difficult to differentiate protagon from fat by the osmium darkening in alcohol, but can be more readily detected after freezing and washing with alcohol. In the hardened preparation small holes will be observed resembling fine drops of fat cells that have been washed out. In the course of nephritic changes these granules extend from the canaliculi into the inter-cellular tissue where the foreign groups finally assume a white mass with stellate margins. In the tuberi contorti these white specks may be seen in the cortex of the organ. This substance when found in the kidney is a pathognomonic symptom of nephritis, and may be of practical use when found in the urine. It is absent in fatty degeneration of the kidney, diabetes and chronic cachexia. The urinary sediment when polarised with the assistance of the microscope and the tinctorial reaction is sufficient to distinguish the presence of protagon. It is also present in atheroma of the vessels, as white patches on the altered intima as well as different tumours such as adenoma xanthoma, tuberosum, and the flat epithelial cells or cylindrical in cancer. It is worthy to note that the crystalin form never appears in the latter cases, but the proportion of nitrogen and phosphorus is the same in nephritis as met with in the brain, but, strange to say, the refractive power of the same substance in the kidney differs from that met with in the brain and analytically acts more like an ester of cholesterol.

AMAUROSIS AFTER PARAFFIN INJECTIONS.

Mintz records two cases of blindness which he attributes to the plastic injections of paraffin, into the nose to relieve a saddle-back appearance of the organ. He pointed to a third case which he feared would end with the same disaster. He thought it the duty of every practitioner to warn the patient against any such risk.

PROSTATIC HYPERTROPHY.

Lichtenstern showed a patient on whom he had operated seven years ago by removing the prostate gland. He was now perfectly able to micturate naturally and with ease, which he considered justified prostaticectomy.

HUNGARY.

Budapest, May 6th, 1906.

At a recent meeting of the Royal Hungarian Medical Society, Professor Dr. Tuszkaï Odön of Marienbad read a paper on the

EMPLOYMENT OF HEROIN IN GYNÆCOLOGY.

According to the statistics of the last three years, 375 patients out of 10,101 (3.87 per cent.), in the out-patient department, suffered from carcinoma. Among these only 105 (11 per cent.) were considered suitable for operation of any kind, and in only seventeen cases was total removal indicated. The other patients, who wander from one hospital to another, consult the

surgeon chiefly in order to obtain alleviation of their painful symptoms. The pain associated with cancerous affections of the womb soon defies the drugs in general use, and therefore I decided to administer heroinum hydrochloricum recommended by Dreser, Gerhardt, and others. Compresses soaked in a 1 per cent. glycerine solution of heroin were used in twenty hospital cases. In half the cases the pain was due to peritoneal irritation; in the other half to inoperable uterine cancer.

In cases of ascending gonorrhœal perimetritis, as well as in cases of diseases of the adnexa, I succeeded in diminishing the pain. In one case of inoperable cancer, I obtained a remarkably satisfactory result. Heroin proved useless in cases in which the cancerous degeneration involved the pelvic connective tissue and the glands. In cases of nervous restlessness and sleeplessness, and in hysterical women the administration of heroin gave little or no relief.

Professor Dr. Rona Samuel exhibited a case of EXANTHEMA UNIVERSALE TUBEROSUM ET FLANIUM, of seven years' standing, in a girl, æt. 8. He had shown the girl four years ago, and his object now is to demonstrate the subsequent course. The disease started originally in the skin of the forehead. As to the treatment, he said that in all such cases the only radical cure is the operative excision of the xanthoma, but this can be performed only in cases in which the affection is not universal, as in the present case. Electrolysis is sometimes followed by satisfactory recovery, even in certain cases where one would hardly expect it. Its only disadvantage is that recurrence of the xanthoma is common after its use. The patient exhibited by him in whom, by reason of the generalised nature of the affection, neither of the above mentioned methods was applicable, is taking phosphorus and turpentine internally, as recommended by Besnier.

Dr. Hudovering read a paper on the

TABES OF MARRIED COUPLES.

Up to the present twenty-seven cases of tabes conjugalis are recorded in the literature of the subject, Hudovering now placed on record three further cases of the kind. It must be premised that in all the three couples the tabes was subsequent to syphilis, a relationship which existed in the recorded cases; in fact, in twenty couples out of twenty-four, syphilitic infection was distinguished with certainty, in three couples there was reason to suspect it, and only one couple proved to be really free from syphilis. It follows that in 96.3 per cent. of the conjugal tabes cases there was antecedent syphilitic infection. The theory first brought forward by Lougard is that tabes and general paralysis, while the remainder are free from any sequelæ of the kind, is not to be sought in the above-named affinity of the syphilitic virus for the central nervous system, but that this special predisposition is to be sought for in another direction, perhaps in the congenital or acquired particular disposition of the nervous system.

LETTERS TO THE EDITOR.

THE "DAILIES."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is probable that most of us, when we find, in one of the dailies as we look through it every morning, an article on some medical subject, or some notice of a recent discovery, such as a new bacillus, or a new disease, or a new and wonderful process of treating something or other such as cancer or consumption, we read it with some attention. It is probable that many of us smile quietly to ourselves as we think how the poor Public may be deluded by this kind of literature. There does not seem to be any class of subjects which is dealt with in the same way in the dailies as matters medical. The law is treated differently, and religious matters are not advertised and put before the public in such exaggerated and misleading terms. So it is as well the question has been thought deserving of your attention of late. It is well that you

should be assured by some of your readers that you have every reason to give this subject your consideration, as it is in the interest of the public from every point of view that they should be protected from what can and does prove of more harm than good to them.

I am, Sir, yours truly,
ONE OF YOUR READERS.

MIDWIFERY FORCEPS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As it seems desirable for several reasons to avoid the necessity of introducing the left lower blade first, I have devised a pattern of midwifery forceps, which seems to meet this requirement. In these forceps, it will be noticed that the blades do not cross, that the lock is not at the junction of the handle and the blade, but at the end of the handles, and that the lock can be fixed by a single turn of a stud. To prevent the blades from rolling one on the other, a guide peg in the lower blade fits into a slot in the upper. A small swivel screw attached at the junction of the blades and handle prevents the handles from flying apart; a traction rod

can be used if necessary, as in the illustration.

I have used these forceps in a great number of cases, and others as well as myself have been surprised at the ease of application. The forceps were made for me by the Medical Supply Association, 228, Grays Inn Road, London.

I am, Sir, yours truly,
H. TAYLOR MORGAN, M.D.

NEW MEDICAL PREPARATIONS AND APPLIANCES.

BURROUGHS WELLCOME'S THROAT PASTILLES

Much has been recently written about dust, especially in relation to sore throats and nasal catarrhs. The mechanical irritation of the throat by dust particles, and the action of pathogenic micro-organisms, may obviously be in appropriate cases, combated, if not prevented, by suitable topical applications. It would seem that in cases of sore throat resulting from dust particles, the protective soothing effect of mucin is indicated, and that in such cases the natural mucous secretion should be reinforced. This is effected conveniently by the use of Tabloid Mucin compound, which may be slowly dissolved in the mouth, or else made into solution with water and applied as a gargle or throat paint. The importance of maintaining a continuous suffusion of the mucous membrane of the mouth and throat with demulcent and antiseptic agents, is generally recognised. Pastilles which dissolve gradually in the mouth and provide a regular uniform strength of solution, afford the easiest and most pleasant form of obtaining such medication. The Tabloid Pastilles of Glycerin, Lemon juice, and of the valuable volatile stimulating antiseptic 'Pinol' red gum and cocaine, morphine and ipecacuanha, will be found acceptable and efficacious. Other Tabloid Antiseptic products are also beneficial. Such treatment, both preventive and curative, will commend itself as rational and worthy of trial to the general body of the medical profession.

CASTOR OIL POWDER.

THERE is always room for a new aperient—or, rather, in this particular case, for a new form of aperient. Our old friend castor oil has various disadvantages, chief of which is the unpleasant taste and smell, not to mention the ease with which it can be adulterated. A good substitute is offered in the shape of a castor oil powder, made by R. Demuth, 61, Mark Lane, London, E.C. It is a white, palatable powder, and in our hands has proved a safe, trustworthy, and mild, but efficient purgative. Like castor oil, it is specially suitable for children and delicate adults.

NEW LINEN BELTS AND BANDAGES.

WE have received from Messrs. John Clarke and Co., of Belfast, the well-known linen manufacturers, specimens of their latest productions in medical appliances. Within the last few months this firm have added to their former medical specialities the following: Many-tailed bandages of different sizes to be used instead of flannel. Square napkins to use as a final cover for dressings applied to wounds after operation; T bandages; Spica bandages, abdominal belts, and obstetric binders. The samples which we have received are all made of "Irish Linen Mesh," which may be described as a loosely woven and most elastic material, composed of linen yarn. It is porous to a high degree, and strong, and seems to us to be an ideal material for the purposes for which it is made. The bandages can be repeatedly washed and sterilised, and so can be made to fully repay their initial cost. We understand that Messrs. Clarke will be glad to send a specimen of the material to any medical man who applies for it. Messrs. Clarke also make a special form of twisted linen thread which is intended to take the place of other forms of non-absorbable suture materials. This material is at least as strong, if not stronger than silk of a similar thickness. It is put up in tiny balls, each of which contains a yard and a half, or in hanks of twelve yards in length.

Society for Relief of Widows and Orphans of Medical Men.

THE Annual General Meeting of this Society was held on May 3rd, Mr. Willett, Vice-President, in the chair.

The proceedings were opened by the chairman referring to the great loss the Society had sustained by the death of the late President, Mr. Christopher Heath, F.R.C.S., who had always taken the greatest interest in the Society's welfare, and had been a most regular attendant at its meetings. A formal resolution of condolence was passed from the chair. A cordial vote of thanks was moved to the Editors of the medical journals for their unfailing courtesy in inserting the reports of the Society from time to time; this was carried unanimously.

During the year six new members were elected, five members died, and two resigned. At the end of the year there were 148 life members and 146 subscribers. Four widows were elected, and two widows died, there being 54 in receipt of pensions at the end of the year. Three orphans were elected, making a total of 19 in receipt of pensions.

The income derived from the invested funds of the Society was £3,098 19s. 2d., from subscriptions £300 6s. 2d., from donations £23 1s., from life subscriptions £134 8s., and a legacy of £250 had been received during the year.

£3,241 had been distributed among the annuitants of the Charity. The working expenses of the Society for the year were £248 16s. 7d.

Dr. George Fielding Blandford was unanimously elected president, and Dr. F. de Havilland-Hall one of the treasurers. Six directors were elected in place of the six seniors who retired according to the Bye-laws.

Full particulars of the many advantages secured to members of the profession joining the Society, and proposal forms for membership can be obtained on application to the Secretary at the offices of the Society, 11, Chandos Street, Cavendish Square, London.

MEDICAL NEWS IN BRIEF.

The Royal Commission on the Care and Control of the Feeble-minded.

THIS Commission, which has already held a number of sittings in London, sat in Dublin on Saturday last to hear evidence. Amongst the witnesses examined were the Registrar-General, Dr. Stewart Woodhouse, medical member of the Prisons Board; Dr. R. G. Dowdall, Resident Medical Officer of Mountjoy Prison; and Mr. J. Fagan, F.R.C.S., Inspector of Reformatory and Industrial Schools. The Registrar-General's evidence showed that the increase of lunatics and idiots in Ireland was very great. In 1861 their proportion to that of the whole population was 1 in 411; in 1871, 1 in 328; in 1881, 1 in 281; in 1891, 1 in 222; and in 1901, 1 in 178. He considered that an important cause was the marriage of feeble-minded persons, and as this usually occurred during a supposed lucid interval of the person so afflicted he considered the law in this respect required to be changed. He also considered that feeble-minded women and girls frequently became the mothers of illegitimate children. He submitted a return showing the proportion of the insane per 10,000 of the population in England and Wales, Scotland and Ireland at the census of 1871, 1881, 1891, and 1901. In England and Wales the proportion of the insane per 10,000 of the population increased from 30.39 in 1871 to 40.78 in 1901, in Scotland the proportion per 10,000 increased from 33.97 in 1871 to 45.37 in 1901, and in Ireland the proportion of the mentally deranged per 10,000 of the population rose from 30.49 in 1871 to 36.18 in 1901. Thus Ireland occupied the unhappy position of having by far the highest proportion of insane in its population, Scotland coming next, while England and Wales stood third in the list. A considerable factor in the increase shown by the last census was in his opinion, the return of Irish immigrants from the United States who had lost their health and reason whilst working there. Dr. Stewart Woodhouse, F.R.C.S.I., medical member of the General Prisons Board, Ireland, in the course of his evidence said the number of feeble-minded in Irish prisons was not large. In Maryboro' Convict Prison out of about 240 convicts only 5 or 6 could be so described, and even in some of these few criminal mindedness was the more prominent characteristic. In Ireland, a Parkhurst was unnecessary. The number transferred each year from local prisons to district asylums was large, being 51 in 1903 and 102 in 1897. The largest Irish prisons, Mountjoy Male and Belfast Male, had a daily average population of under 400 each, and the number amongst them that could be classed as feeble-minded would be small and variable. Dr. R. G. Dowdall, D.Ph., Resident Medical Officer of Mountjoy Prison, stated in his evidence that the number of prisoners committed to that prison during the year ended December 31st, 1905, was 8,901—4,171 males, and 4,730 females. Of these 16 males and 4 females were mentally deficient, and quite unfit for prison discipline. Mr. John Fagan, F.R.C.S., Inspector of Reformatory and Industrial Schools in Ireland, set out in his evidence that, excluding voluntary cases, there were 7,951 inmates—3,670 boys and 4,281 girls—in industrial schools at the end of 1905, whilst at the same date there were 559 (520 boys and 39 girls) in reformatory schools. The Commission will not sit again in Ireland.

Royal College of Surgeons in Ireland—Election of Examiners.

At a meeting of the President, Vice-President, and Council, the following Examiners were elected:—
Court "A." For Conjoint License, Diploma in Public Health, and Preliminary: Anatomy—Alexander Fraser, F.R.C.S.; Bertram C. A. Windle, B.S., Univ. Dub. Surgery—Alexander Blaney, F.R.C.S.; F. Conway-Dwyer, F.R.C.S. John Dundon, F.R.C.S.; Richard Lane-Joynt, F.R.C.S. Pathology and Bacteriology—Arthur Hamilton White, L.R.C.S. Mid-

wifery and Gynæcology—Frederick W. Kidd, L.R.C.S. Biology—John J. Burgess, F.R.C.S. Ophthalmology—Arthur H. Benson, F.R.C.S.; Herbert C. Mooney, F.R.C.S. Sanitary Law and Vital Statistics—Edward Francis Stephenson, F.R.C.S., D.P.H. Languages—Woodroffe, L. J. Mathematics, Physics, Dictation, and English Essay—J. W. Tristram.

Court "B." Fellowship, License in Surgery (for registered practitioners), License in Midwifery (for registered practitioners), and License in Dental Surgery. Anatomy—Patrick Joseph Fagan, F.R.C.S.; Alexander Frazer, F.R.C.S. Surgery—Alexander Blaney, F.R.C.S.; F. Conway-Dwyer, F.R.C.S.; Thomas E. Gordon, F.R.C.S.; Richard Lane-Joynt, F.R.C.S. Pathology and Bacteriology—Leveson Gower Gunn, F.R.C.S.; Arthur Hamilton White, L.R.C.S. Midwifery and Gynæcology—Frederick W. Kidd, L.R.C.S. Chemistry and Physics—Edwin Lapper, L.R.C.S.; Robert J. Montgomery, F.R.C.S. Dental Surgery and Pathology—George M. P. Murray, F.R.C.S.; William G. Story, L.D.S. Mechanical Dentistry—Kevin E. O'Duffy, L.D.S. Edin.; Daniel L. Rogers, L.D.S.

University of Durham.

At the convocation held on Saturday, April 28th, 1906, the following Degrees were conferred, viz.:

Doctor in Medicine—Charles H. Clarke, M.B., B.S. Dur.; Ida E. Fox, M.B., B.S. Dur.; Harold L. Heslop, M.B., B.S. Dur.; Herbert L. Noel-Cox, M.B. Dur.; Thomas Y. Simpson, M.B., B.S. Dur.; James B. Waters, M.B., B.S. Dur.

Doctor in Medicine for Practitioners of Fifteen Years' Standing—Bennet H. Andrew, M.R.C.S., L.R.C.P., L.S.A.; Henry Buxton, F.R.C.S.E., L.R.C.P., L.F.P.S.G.; Ernest C. Freeman, M.R.C.S., L.R.C.P., D.P.H.; John F. Nall, F.R.C.S.; Richard R. Sleman, M.A., L.S.A.; James P. Walker, M.R.C.S., L.R.C.P.; Alfred W. Waller, M.R.C.S., L.R.C.P.

Bachelor in Medicine (M.B.)—Frederick W. Cheese, M.R.C.S., L.R.C.P.; James H. Cooke, B.Litt.; Hamilton Drummond, Horsley Drummond, Wilfrid Fairclough, Archibald Finlay; John Galloway, L.R.C.P. & S. Ed., L.F.P.S.G.; Sampson G. V. Harris, M.R.C.S., L.R.C.P., D.P.H.; Arthur B. Jones; John C. Pearce, A.Sc.; Robert B. Reed, William Seymour, Frank T. Simpson, Frederick J. Strachan, Edward Tate, Arthur J. Turner, Robert J. Weidner, Robert J. Willan.

Bachelor in Surgery (B.S.)—F. W. Cheese, M.R.C.S., L.R.C.P.; J. H. Cooke, B.Litt.; H. Drummond, H. Drummond, W. Fairclough, A. Finlay, J. Galloway, L.R.C.P. and S. Ed., L.F.P.S.G.; S. G. V. Harris, M.R.C.S., L.R.C.P., D.P.H.; S. H. Hawley, M.D., B.Sc., D.P.H.; A. B. Jones, J. C. Pearce, A.Sc.; R. B. Reed, W. Seymour, F. J. Strachan, E. Tate, A. J. Turner, R. J. Weidner, R. J. Willan.

Bachelor in Hygiene (B.Hy.)—John W. H. Morrison, M.B., B.S. Dur.; Henry Renney, M.D., B.S., D.P.H. Dur.; Herbert J. Slade, M.B., B.S., Dur., M.R.C.S., L.R.C.P.

And the following received the—

Diploma in Public Health (D.P.H.)—James A. Mitchell, M.B., Ch.B., Glas.; John W. H. Morrison, M.B., B.S., Dur.; Herbert J. Slade, M.B., B.S. Dur., M.R.C.S., L.R.C.P.

DR. J. LINDSAY STEVEN has been elected President of the Glasgow Medico-Chirurgical Society. A Clinical Lecture on "General Cystic Degeneration or Transformation of the Kidneys in the Adult" by Dr. Steven, will be found in our present number.

DR. G. FIELDING BLANDFORD was elected at the annual general meeting of the Society for Relief of Widows and Orphans of Medical Men, President, in the place of Mr. Christopher Heath, F.R.C.S., deceased.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specialy Compiled for THE MEDICAL PRESS AND CIRCULAR.

SUMMARY OF RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Death from Uterine Fibromyomata Pellanda (*These de Lyon de Lyon*) (*Journ. of Obst. and Gynaecology* April, 1906). In this thesis the writer has analysed 191 cases of death directly caused by uterine fibroids in which no surgical treatment was adopted. The causes of death are as follow:—1. Infection, 49·5 per cent. This is the most frequent cause of death and in the majority of cases appears to depend on association with labour or abortion. 2. Compression of abdominal or pelvic viscera, 25·8 per cent. 3. Thrombosis of the pelvic venous sinuses and pulmonary embolism, cardiac lesions (myocardites, valvular insufficiency) and sudden syncope, 11·1 per cent. 4. Hæmorrhage, 6·4 per cent.; this group is divided into two classes, intra-uterine and intra-peritoneal. 5. Cachexia, 5·2 per cent., a state brought about by many different pathological conditions such as compression of abdominal viscera, exhaustion from hæmorrhage, slow infection, coproæmia, phlebitis, cardiac and renal lesions. 6. Torsion of pedunculated subserous fibroids, 3 cases. The mean age at which death occurred was 44½ years, it occurred earliest (42½) from infection and latest from cachexia (59), compression coming between these, 47½. F.

Intra-peritoneal Hæmorrhage in Uterine Fibromyomata.—Perrier. (*These de Lyon Journ. Obst. and Gynaecol.* April, 1906). Bleeding into the peritoneal cavity is a rare accident when due to the presence of a subserous uterine fibromyoma, yet in the writer's opinion it accounts for many cases of hæmatocèle as due to rupture of an extra-uterine pregnancy. Such hæmorrhage may be caused by two different mechanisms—namely, 1. By rupture of subserous varices on the surface of the fibro-myomatous uterus. 2. By rupture of peritoneal adhesions. In the former case the hæmorrhage is diffuse and occurs into a healthy peritoneum; it is fulminating in type and demands immediate operative intervention. F.

Prophylaxis of Abdominal Adhesions.—C. G. Cumston, M.D. (*Amer. Journ. of Obst.*, March, 1906). It is quite impossible to prevent the formation of adhesions due to intra abdominal inflammatory processes, neoplasms and traumatism and in reality only adhesions following abdominal operations may be to a certain extent prevented. Strictest asepsis is, of course, the greatest requisite, and includes the well-known principle of not touching any parts with instruments or hands which are not surgically clean. The so-called toilet of the abdominal cavity, in getting rid of blood, or the contents of cysts is unnecessary in most cases, but when this is required flushing with sterile salt solution, followed by careful mopping, may be resorted to. Chemical solutions should always be kept at a safe distance from the operating table, and are only to be used for rinsing the hands during an operation. Another important point is keeping the peritoneum warm and moist during the operation, by covering it over at every point where it comes in contact with the air, with warm moist gauze sponges wrung out in normal salt solution or the following, which is used in Slinger's clinic where a marked decrease in intestinal disturbances following laparotomies has been observed: sodium bicarb, 2·5; sodium chloride, 9·5; distilled water, 1,000; suture of the abdominal walls requires articular care, because, to a great extent, it tends to the formation of adhesions; here the writer recommends the closure of the peritoneum with fine catgut sutures, applied according to Lembert's method, so that when the peritoneal wound is closed healthy peritoneum is approximated to healthy peritoneum. The fascia is united with a continuous kangaroo tendon suture and

the skin and fat with silkworm gut. In order to prevent adhesions between the peritoneal wound surfaces in all cases, and especially those where extensive surfaces remain after operation, secure the keeping of the serous surface in constant motion, so that no two raw peritoneal surfaces remain in contact with one another long enough to result in union between them; this is a more rational method than Muller's, of pouring large amounts of sterile salt solution into the abdominal cavity. The principal way to stimulate a constant change of contact of the peritoneal surfaces is to stimulate peristalsis immediately after an abdominal operation by some of the following means—subcutaneous use of physostigma immediately after operation and continued three times daily for three days. Ditzel's practice is to give a large soap and water enema soon after operation, and this is followed several hours later by an injection of glycerine. A less active means for continually changing the position of the intra-peritoneal surfaces is massage of the abdomen which increases peristalsis, deepens respiration, and is a prophylactic for post-operative pneumonia. Besides the above-mentioned means another method used by Ditzel is to excise a bit of fat from the abdominal wall, and, squeezing it out, to rub it into the raw peritoneal surface. F.

Extirpation of Bartholin's Cysts by a New Process.—Pozzi (*Annales de Gynecol. et d'Obstet.* Dec., 1905.)—Operators are aware of the difficulties met with in getting these tumours out whole, and that it is not easy to remove every portion of the living membrane when once such cysts are opened or burst during dissection. In order to facilitate their complete removal the writer injects spermaceti into the cavity the evening before the operation. This solidifies after injection, and the tumour can then quite easily be removed as a solid mass. F.

Malignant and Benign Degenerations of Uterine Myomata.—Winter (*Zeitschrift f. Geburtsh. und Gynak.* Band. 57.) says the myoma is greatly predisposed to secondary degenerations, since the uterus, its native soil, is so often attacked by disturbances of nutrition and diseases which can influence the life of the tumour. Carcinoma has an intimate connection with myomata. It occurs much more frequently with them than without them. Cancer of the body occurs just as often as cancer of the cervix in their presence. Otherwise cancer of the cervix is about fifteen times more frequent than that of the body, so that the inclination of myomata to induce cancer of the body must be particularly great. Cervical cancer occurs in 2 per cent., and cancer of the body in 1·2 per cent., of myomatous uteri. This combination is too rare to become an indication for operation in every case. Also the routine removal of the cervix during hysterectomy, for myomata, in order to prevent its becoming the seat of cancer, is not necessary, because in the 17 published cases of cancer of the stump the cancer really only originated 7 times after the operation. At the same time this combination must receive every attention, so that an early diagnosis may be made if cancer should arise. This is difficult and must depend on the characteristic symptoms, which are not usual with pure myomata. These are, above all, hæmorrhages in the menopause, sero-sanguineous discharge and uterine pains. In their presence the uterus must be curetted for microscopical examination. It is difficult to estimate the frequency of sarcomatous degeneration, because the microscope alone makes the diagnosis certain. Considering 753 cases, Winter estimates the frequency at about 2 per cent. in subserous, 4 per cent. in interstitial, and

8.7 per cent in submucous myomata. This frequency makes a certain clinical diagnosis most desirable. This is difficult in the submucous variety, because the symptoms of the sarcoma are so like those of the myoma; therefore every extirpated submucous myoma must be thoroughly examined microscopically. The diagnosis in interstitial myomata is still more difficult; it depends usually on the symptoms, irregular hæmorrhages, uterine pains, loss of flesh and strength. The occurrence of ascites, adhesions or metastasis points to sarcomatous degeneration. In the subserous myomata the diagnosis in three cases could only be arrived at microscopically. Benign degenerations are much more frequent. This is due to the changes in nutrition of the myomata during menstruation and pregnancy, and to the different diseases to which the uterus is liable. The degenerations may occur as atrophic or infectious conditions, necrosis or softening. Complete necrosis of the myoma arises from disturbances of nutrition, which affect the whole tumour at the same time. For example, in submucous from expulsion, in subserous from twisting of the pedicle. Complete necrosis of interstitial myomata has been little studied. In appearance the tumour is flesh red. Its cause must be sought for in the uterine wall from which the myoma receives its nutrition. One must particularly consider the very important changes in nutrition of the tumour bed during parturition, and also in torsion of the uterus, ergot treatment and diseases of the blood vessels. The symptoms consist of severe and usually irregular hæmorrhages, pain, and the general condition of the patient, which Freund has described as auto-intoxication. The results of necrosis are very severe and usually fatal, unless the myoma is extirpated in time. The diagnosis is difficult, and may be made when, closely following on parturition, the above symptoms develop. Treatment must always be operative and preferably radical. G.

The Bacteriology of Puerperal Infection.—A bacteriological contribution to puerperal infection is recorded by Hellendall (*Beiträge zur Geburtsh und Gynäk.*, Band x., Heft 1), who from the examination of fifty-two cases of abortion comes to the following conclusions. In every case of protracted abortion the uterus becomes infected in the long run. The bacteria either ascend from the vagina and vulva or are introduced on the hands or instruments. Spontaneous ascent of infection depends on the retention of dead matter in the uterus, and does not occur without it. The usual mode of ascent is that the bacteria infect the blood clots hanging from the uterine cavity. The infection ascends either between the membranes or extends from the liquor amnii through the amnion into the intervillous spaces. Consequently the temperature must be frequently taken during protracted or induced abortion and a rise indicates immediate emptying and disinfection of the uterus. With incomplete abortion the retained fragments are infected a long time before fever arises, and therefore in this variety the uterus should always be emptied at once. G.

The Connection Between the Appendix and the Lymphatic Apparatus of the Intestinal Tract.—Albrecht (*Monat. f. Geburtsh und Gynäk.*, Feb., 1906) writes that the appendix belongs to the group of the lymphatic organs of the body. In the pathology of the appendix there is a remarkable analogy between its diseases and those of the tonsil. Its position at the entrance to the colon, in connection with the follicular apparatus of the ileum, not unlike the position of the tonsil at the beginning of the pharynx, must make us consider whether physiologically it may not be looked upon as the tonsil of the colon. One finds everywhere in the intestinal tract an accumulation of lymphatic organs where narrowings of the canal and niches are present. Therefore from its localisation the intimate connection between the appendix and the lymphatic organs may be inferred. Moreover, it places at the beginning of the colon a large lymphocyte supply in the same way as Peyer's patches do higher up. G.

A Case of Central Rupture of the Perinæum (*Brit. Med. Journ.*, April 14th, 1906).—Dodson reports a case in which a laceration of this kind occurred in a primipara, æt. 21. The labour was rapid and the pains very strong. A central tear was noticed as the head came well down on to the perinæum; a strong pain then forced the child through the opening. Upon examining the condition it was found that the rectal and vaginal orifices were intact. The placenta was born through the opening. The wound was 5 in. long in the median line of the perinæum, from the anterior end it ran outwards and forwards to the left side of the vaginal orifice for about 2 in., while posteriorly, at about 1 in. from the anus, it was continued backwards and outwards for about 1½ in. by the side of the rectum. It is pointed out that usually such a laceration involves either vaginal or rectal orifice. The child weighed 6 lb. 12 oz. H.

OBITUARY.

SURGEON-GENERAL SIBTHORPE, F.R.C.P.I.

WE much regret to have to chronicle the death of Surgeon-General Sibthorpe, late of the Royal Army Medical Staff, on May 4th, at his residence in Dublin after a short illness. The late Surgeon-General was a member of a well-known Dublin family. Born in 1847, he qualified as a Licentiate of the Royal College of Surgeons of Ireland in 1869, and in 1880 became a Fellow of the Royal College of Physicians. He joined the Army Medical Service, in which he saw much hard work. His principal campaign was that in Burmah, in 1885, when he received the medal and clasp and was honourably mentioned in despatches. He was one of the few medical officers who was present at the capture of King Thebaw. He was advanced to the rank of Brigade-Surgeon in 1882, Brigade-Surgeon General in 1886, and as Deputy Surgeon-General served in the Afghan war, when he was again mentioned in despatches and received the medal. In addition to his military duties, Surgeon-General Sibthorpe found time for literary work, and was the author of an important work on Clinical Research in India. In 1897 he received the military order of Commander of the Bath. He died at the early age of fifty-nine, to the deep regret of a large circle of professional and other friends. His funeral, which took place on Monday last, was attended by the President and Fellows of the Royal College of Physicians.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of this society was held on the 27th ult. There were present—Dr. de Havilland-Hall, in the Chair; Mr. Frank Wallace, Dr. J. Pickett, Dr. St. Clair B. Shadwell, Dr. Fred. S. Palmer, Dr. J. Brindley James, Dr. W. Knowsley Sibley, Mr. J. F. Colyer, Dr. M. Greenwood, Mr. Edward Bartlett, and Dr. J. B. Ball. The Committee were mainly occupied in examining the draft of the report for the year 1905. It was resolved that the annual general meeting should be held as usual at the Medical Society of London, Chandos Street, Cavendish Square, on Thursday, May 17th, at 5. The report to be then presented shows that in 1905 the business of the society was in every way satisfactory, producing a large increase in the funds, which now amount to over two hundred thousand pounds. The number of new entrants was greater than in any previous year of the society's working. Prospectuses and all particulars on application to Mr. F. Addiscott, Sec., Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

PBS.—The last number of the Registrar-General's Returns would give the information required.

META.—Our correspondent has omitted to enclose his card. Mr. T. V. L.—We must see the work before making the statement you ask for.

PATERFAMILIAS (Leeds).—We sympathise with our correspondent in the extent to which his son has been victimised by the firm of quacks, but in the present state of the law, unfortunately, there is no remedy against them.

M.D.—The name does not appear in the current *Medical Register*. Probably the "degrees" are of American origin.

DR. L. R. C.—From the cases recorded in the third edition of Dr. Shaw-Mackenzie's work on "cancer," the trypan treatment for cancer has passed beyond the experimental stage. For particulars of the method of practising it we must refer you to the work in question.

A YOUNG PRACTITIONER is referred for answer to "Meta" and "Behind the Scenes" in this column.

THE KEELEY INSTITUTE FOR DRUNKARDS.

A CORRESPONDENT has cut out and sent some pages of advertisements of the so-called "Keeley Institute" for the cure of the drink habit, in the hope that we will take this in our list for exposure. Our correspondent apparently does not know that we have already done what he suggests. We went fully into the matter when it was first introduced from America to this country ten years since. We laid bare the whole scheme in these columns during 1896-97, and had to bear the trouble and expense of a law suit at the hands of its promoters. Before, however, the case was heard, Dr. Keeley withdrew his claim, and the proceedings were quashed.

L.R.C.P.LOND., M.R.C.S.—In our opinion the matter is more one of a breach of good taste than one of offence against ethical law.

A SLIGHT MISUNDERSTANDING.

DOCTOR (to Mrs. Perkins, whose husband is ill): "Has he had any liquid intervals?" Mrs. Perkins (with dignity): "E's 'ad nothing except what you ordered, doctor."—*Exchange.*

"**BEHIND THE SCENES**" has sent us two communications, but in neither has he given his name and address. No notice is taken by us of anything not vouched for by the name of the contributor, a rule from which we never depart.

DR. L. C. (Manchester).—The literature of the subject is voluminous. If there be any one point you wish to elaborate there are experts who can give you the list of necessary references. Any further information we may have is at your disposal.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MAY 9th.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—6.15 p.m. Meeting.

SOCIETY OF ARTS (John Street, Adelphi, W.C.).—8 p.m. Paper:—Prof. T. Oliver: Bridge Building by means of Caissons, including Remarks upon Compressed Air Illness.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. P. L. Daniel: Clinique. (Surgical). 5.15 p.m. Lecture:—Dr. G. H. Savage: Eccentricity and Insanity.

THURSDAY, MAY 10th.

HARVEIAN SOCIETY OF LONDON (Paddington Infirmary, Harrow Road, W.).—8.30 p.m. Clinical Meeting. Cases will be shown.

BRITISH GYNECOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Paper.—Mrs. Scharlieb: The Advantages of the Abdominal Route in Operations for Cancer of the Uterus.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m. Lecture.—Mr. C. Nourse: Some Points in the Diagnosis and Treatment of Frontal Sinusitis.

FRIDAY, MAY 11th.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m. Papers.—Mr. C. Wallace: Case of Cystic Tumour of the Spermatic Cord.—Mr. A. C. Hudson: Carcinoma of the Thyroid Gland.

—Mr. E. W. Boughton: Case of Perforated Gastric Ulcer treated by Evisceration and Irrigation.—Mr. J. D. Malocm: Complete Removal of a Multilocular Cyst of the Pancreas; Intestinal Anastomosis for Partial Obstruction 16 Days later.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. S. Stephenson: Clinique. (Eye.)

Vacancies.

- Birmingham and Midland Eye Hospital.—Resident Medical Officer. Salary £100 per annum. Applications to the Chairman of the Medical Board.
- Brecknock County and Borough Infirmary.—Resident House Surgeon. Salary £100 per annum, with furnished apartments, board, attendance, fire and gas. Applications to W. Powell Price, Secretary.—The Bulwark, Brecon, South Wales.
- City of London Hospital for Diseases of the Chest, Victoria Park, E.—Resident Medical Officer. Salary £100 per annum, with board, &c. Applications to the Secretary.
- Devon County Asylum.—Third Assistant Medical Officer. Salary £125 per annum. Application to Medical Superintendent, County Asylum, Exminster.
- Hants County Asylum.—Second Assistant Medical Officer. Salary £175 per annum, with furnished apartments, board, washing, and attendance. Applications to the Visiting Committee, Hants County Asylum, Fareham.
- Killarney District Lunatic Asylum.—Assistant Medical Officer. Salary £100 per annum and allowances. Applications to E. W. Griffin, Resident Medical Superintendent. (See advt.)
- Metropolitan Asylums Board.—The Downs School, Sutton, Surrey (for Children with Ringworm).—Assistant Medical Officer. Salary £250 per annum and dinner daily. Applications to the Clerk, Metropolitan Asylums Board, Embankment, London, E.C.
- Somerset and Bath Asylum, Wells.—Second Assistant Medical Officer. Salary £130 per annum, with board, lodging, washing, and attendance. Applications to the Superintendent.
- West Riding County Council.—Scaleford Park (Private Asylum), Burley-in-Wharfedale.—Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, attendance, &c. Applications to the Physician Superintendent.
- West Kent General Hospital, Maidstone.—Senior House Surgeon. Salary £100 per annum, with board and residence. Applications to the Secretary.

Appointments.

- ASHWIN, R. H., M.B.Lond.**, Certifying Surgeon under the Factory and Workshop Act for the Market Weighton District of the county of York.
- BRISCOE, WILLIAM THOMAS, M.D., M.Ch.Dub.**, Medical Officer for the Pewsham District by the Chippenham (Wilts) Board of Guardians.
- CARDOZO, S. N., L.R.C.P.Lond., M.R.C.S.**, Medical Officer and Public Vaccinator for the Northampton District by the Southampton (Devon) Board of Guardians.
- HARDING, CHARLES HEADLEY, M.R.C.S., L.R.C.P.Lond.**, Medical Officer to the Northern Division of the Whittlesea Union and Public Vaccinator to the Whittlesea Rural District.
- HARTFORD, A. H. B., L.R.C.P.** and **S.Irel.**, Certifying Surgeon under the Factory and Workshop Act for the Christchurch District of the county of Hants.
- MAOKEOWN, W. J., B.A., M.B., B.Ch.R.U.I.**, Senior Assistant Medical Officer to the County Asylum, Fareham, Hants.
- OLLERENSHAW, ROBERT, M.B., Ch.B.Vict.**, Senior House Surgeon to the Liverpool Infirmary for Children.
- ROGDON, R. B., L.D.S., R.C.S.Eng.**, Assistant Honorary Dental Surgeon to the York County Hospital.
- RENTZSCH, SIGISMUND HANEY, L.R.C.P.Lond., M.R.C.S.**, Honorary Medical Officer to the Stratton (Cornwall) Cottage Hospital.
- ROBSON, JOHN R., M.R.C.S., L.R.C.P.Édin.**, Honorary Ophthalmic Surgeon to the Royal British Female Orphan Asylum, Devonport.
- THOMAS, H. MORTIMER, M.R.C.S., L.R.C.P.Lond.**, House Surgeon at the Royal National Orthopaedic Hospital.
- WAGGETT, ERNEST M.B., B.C.Ontab.**, Surgeon to the newly constituted Department for Diseases of the Throat, Ear, and Nose at Charing Cross Hospital.

Births.

- TYLOR**.—On May 3rd, at Mounpesson House, Wisbech, to Dr. and Mrs. Max Tylor, a daughter.

Marriages.

- DRUMMOND-RUSSELL**.—On May 3rd, at the Oratory, South Kensington, Henry Olpherts Drummond, younger son of the late James Drummond, M.D., of 5 Great Cumberland Place, to Hon. Lilian Russell, daughter of the late Lord Chief Justice of England, and of Lady Russell of Killowen, 6 Hyde Park Gate.
- PARKER-LLOYD DAVIES**.—On May 3rd, at Holy Trinity Church, Guildford, Herbert Francis Parker, M.D.Ontab., M.R.C.S., L.R.C.P., to Edna, daughter of the late David Lloyd Davies, of Wyre Court, Bewdley, and of Mrs. Lloyd Davies, Guildford.
- TINDALL-JACOB**.—On May 3rd, at St. Ann's Church, Dublin, by Rev. Paterson Smyth, D.Litt., vicar, assisted by Rev. Cecil Patton, Rector of Fethard, Tipperary, Albert Alfred Tindall, elder son of A. A. Tindall (MEDICAL PRESS and CIRCULAR, London), of Boughton-Monchelsea, Kent, to Blanche Phoebe, daughter of the late Archibald Hamilton Jacob, M.D., F.R.C.S. (late Surgeon-Oculist to H.M. Queen Victoria), of 23 Ely Place, and Mrs. Jacob, 47 Morehampton Road, Dublin.

Deaths.

- BAINES**.—On May 5th, at 11 Cranley Place, London, Matthew Baines, Esq., V.D., M.D., London, Knt. of Grace of the Order of St. John at Jerusalem.
- GIBBON**.—May 3rd, at 58 Warrior Square, St. Leonards-on-Sea, Harriet Susan Gibbon, eldest daughter of the late James Gibbon, M.D., of Swansea.

THE MEDICAL PRESS AND CIRCULAR.

No. 20.

NOTES AND COMMENTS.

The Darnell Defence Fund.

OUR readers would do well to consider the call on their generosity, which is made by a very representative committee of Belfast medical men, in the case of Dr. Darnell, the defendant in the late case of *Tughan v. Darnell*, to which we have referred on several occasions. As our readers may remember, Dr. Darnell was at first successful, but afterwards he was defeated on an application by the plaintiff for a new trial, and this new trial also went against him. The result is that he has been compelled to meet the expenses of some five distinct hearings of his case. The Medical Defence Union to which he belongs will pay all that it can legally pay to his defence, but even with this there will be a balance of some £800 still owing. Dr. Walton Browne is the Chairman of the Committee which has been jointly appointed by the Ulster Branch of the British Medical Association and the Ulster Medical Society, and Dr. Cecil Shaw and Dr. Thos. Houston are the Honorary Secretaries. Already close on £200 has been promised, but if the appeal is to be a success it must be supported by the medical profession in Ireland generally, and not merely by Dr. Darnell's Belfast confrères.

Trent and other River Waters.

NOTWITHSTANDING the fact that the United Kingdom still leads the world in practical sanitation, there are nevertheless many weak spots in our armour. Curiously enough, one of the most serious is that which concerns the pollution of rivers. Take three great English rivers, the Thames, the Severn, and the Trent. They are one and all extensively contaminated with sewage, yet each furnishes the drinking water supply of large populations, in some cases amounting to millions. To drink sewage-polluted water without sterilisation by heat is to court disaster. Sand-filtration simply remains as a monument of bye-gone effort that achieved a "best possible" under existing conditions of imperfect scientific knowledge. In some parts of the Trent Valley the river is little more than an open sewer, and landed proprietors have actually in more than one instance abandoned its malodorous banks. Dr. Sladen, moreover, the Medical Officer of the Gainsborough Rural District, reports that for years past the great majority of cases of enteric fever in the neighbourhood have arisen through drinking Trent water. Surely this benighted state of affairs must be known to the Local Government Board.

Dr. Freyberger as Expert.

It is to be hoped that the recent inquest upon the death of Major Whyte will bear its fruit in due season. The gallant officer in question paid for his credulity with the supreme penalty of his life.—nothing more nor less. His death resulted from a bed sore which was allowed to develop and to become septic by want of proper medical care and nursing. As every medical man knows, such sores are peculiarly apt to occur and to run a rapid and dangerous course after injuries to the spinal column. As a matter of common professional knowledge, any really qualified practitioner of medicine would be competent to make an authoritative statement to that effect for the guidance of a jury. Mr. Troutbeck, the Westminster coroner, however, who investigated the notorious Christian Science case, will have none of your ordinary general practitioners in his court if by any possibility they can be excluded. Acting on his now invariable rule, he handed over the *post mortem* to his trusty "expert" Dr. Freyberger, who with his usual sagacity discovered a number of gross lesions, and delivered a solemn opinion as to the cause of death—at the usual fees—usual, that is to say, in the case of "experts."

Why draw the line at Powders?

MR. TROUTBECK, in the course of the inquiry, pushed home several logical thrusts at the Scientists. In examining the gentleman described as Dr. George Adcock, who states he retired from medical practice about a year ago, the Coroner elicited the fact that in his Christian Science capacity Dr. Adcock had directed the bed sore to be dusted with "Ektagon" powder. The wound became sweeter, but this the witness attributed to Christian Science. "Then why did you give the powder?" was the inevitable counter-question, to which the quondam medico replied tamely enough, "I had to give something." He further admitted that he had written to Dr. Huxley saying he had opened an abscess while attending deceased. Clearly, if prayer alone can cure disease generally, it is absolutely superfluous to use drugs and open abscesses. In this case a huge collection of pus had formed round the hip joint, with purulent inflammation of the bladder and kidneys—all for want of ordinary medical treatment. The incident smacks of mediæval barbarism, or of the besotted superstitious medicine of the Chinese. It is saddening to find such fatuous folly in the land of Harvey, of Jenner, and of Lister at the beginning of the 20th century, and still more so to

find a qualified medical man pandering to such sinful ignorance.

LEADING ARTICLE.

CHRISTIAN SCIENCE.

ONE interesting characteristic of developing civilisation is the tendency to branch off into various fantastic fashions and other curious intellectual subtleties founded on foolishness as apart from reason. In all the vast range of human follies it would be hard to find one more fatuous than that involved in the extraordinary creed known as Christian Science. Briefly, its followers hold that disease exists simply and solely in the imagination, and that sufferers from this subjective phantom can be relieved by prayer offered by suitable persons—at a suitable fee, be it noted. As an inevitable corollary medical science is superfluous, and the fees payable heretofore to medical men should be accordingly transferred to those who pray. The whole "Science," therefore, clearly rests upon an impudent assumption as to the worthlessness of modern scientific medicine. It attempts to prove the security of its profession by adducing an imposing list of alleged "cures." Needless to say, in many cases there has been nothing but vague and fleeting nervous or hysterical complaints that need no cure. In many others the diagnosis cannot be accepted, as it has been made by untrained persons incompetent to form a judgment. It is the old story of cancer said to have been "cured" by violet leaves, or salt, or some other childish remedy. The assertion is worthless because the existence of the cancer has not been in the first place undeniably proved by the test of the microscope, and by other evidence that is only to be procured by a physician of the highest skill, training, and experience. In other words, the triumphs that the quack proclaims from the housetops are simple clap-trap and fustian, because he has just conjured up an imaginary disease to which he has applied a remedy which also owes its existence to his fertile imagination. When the Christian Scientist is brought to the only public test to which he can be subject, namely, that of a legal inquiry, the absolute hollowness of his claims is speedily exposed. He is shown to be a bogus medical practitioner of the worst type, a danger to the State, and a cruel parasite upon society. Curiously enough, the Christian Scientists include many wealthy and aristocratic followers. Their services are held in assemblages crowded with persons of rank, fashion, wealth and culture. As a form of emotional belief, it is no more subject to the cool analysis of

individual reason than many of the irrational and more or less fantastic observances and irrelevancies incidental to many creeds. A striking instance of complete surrender of individual judgment has come to light in a recent coroner's inquiry into the death of Major Whyte, D.S.O., late of the Lancashire Fusiliers, a man of wide accomplishments and possessed of a ripe experience of mankind. In February, 1903, he unfortunately broke his spine in a hunting accident, and like a wise man of the world at once put himself in the hands of a leading surgeon. In September, 1905, he went to the house of a Christian Scientist named Smith, of Elm Park, London, where he was treated by a course of prayers at a cost of a guinea a week. Before his death in May he was seen by Sir Victor Horsley, who described in graphic language the horror of a septic bed sore—"the most horrible case he had ever seen." The gentleman who appears to have been the actual agent of Major Whyte's conversion was Captain Baynes, who described himself as a practitioner of Christian Science, and stated he had been in the Indian Army for seventeen years. In view of the fatal issue of the case, the question arises whether Captain Baynes has not rendered himself liable to an action for manslaughter like any other irregular medical practitioner. The Solicitor of the Defence Union however, may be trusted to look after that part of the matter, just as it has brought to book a medical man named Adcock, who, after fifteen years' medical experience, appears to have joined the Christian Scientists a year or so ago. At any rate, under his care, also at a guinea a week, the bed sore in Major Whyte's pelvis developed and became septic—a result that would be deemed a standing disgrace to responsible medical treatment and nursing. Mr. Adcock now stands committed for trial on a charge of manslaughter. His adhesion to this grotesque sect of Christian Science is, in our opinion, simply inexplicable. It is to be hoped that recurrent scandals of this kind will be put an end to by the sharp legislative interference of Parliament, through the agency of an amended Medical Act rendering penal all irregular medical practice of this gross nature.

NOTES ON CURRENT TOPICS.

Midwives' Practice.

A REPORT appears in the *Sheffield Daily Telegraph*, May 12th, 1906, of an inquiry held by the Coroner of Sheffield into the death of a two weeks' old child at Hillsborough, a suburb of Sheffield, on Wednesday, May 9th. The child was born on April 26th, mother and infant being attended by a certificated midwife, Ada Loxley. The child appeared to be fairly well up to the day of

its death, when it became very sick, and was taken to a Dr. Rollinson's, and died as it was being carried home. The doctor said that the infant was in a dying condition when it was taken to him, and asserted that the death was due to neglect. The cause of death was said to be gangrene (presumably of the cord and navel, though not actually mentioned) brought on by neglect. Mrs. Franks, the lady inspector, elicited the fact that the midwife, a woman of eight years' experience, had only attended seven out of the ten visits required under the Midwives Bill. Her reason was that she lived a long way off, and that she had told the mother that she would not be able to visit every day. She said that the child was fairly healthy at birth, and although it had been ailing a little, she thought it was getting better. The doctor said that the child had not been properly attended to at birth, and that had a medical man been present, it would have been alive at the time the inquiry was being held. The case was one of the worst he had ever come across. The jury returned a verdict in accordance with the medical evidence, and expressed the opinion that the midwife was censurable for not having given proper and sufficient attention to the deceased.

The Medical Sickness Society.

THE 23rd annual report of the Medical Sickness, Annuity and Life Assurance Friendly Society— to give its full title—will be presented to members on the 17th instant. The continued prosperity of this most excellent undertaking is testified in many ways. First of all 183 new proposals have been received during the past twelve months, the largest number in any year of the Society's working. The amount paid away in benefit to members was £11,132 9s., as against £11,566 in 1904. Perhaps the most gratifying feature of all is the steady and continuous growth of the reserve fund, which, starting with £1,484 in 1884, has reached £196,283 in 1905. The average annual increase for ten years past has been from £10,000 to £11,000. These figures speak for themselves as to the stability and great field of usefulness of the Society. It proves, moreover, that medical men are capable of carrying out a commercial organisation on a sound and successful basis. Since the business was started in 1884 more than £100,000 has been disbursed in sickness benefit to members, and the unspeakable value of self-help has been once again vindicated. Great as the extension of members has been, there still remains a majority of the medical profession without the walls of this most useful organisation.

Another Cure for Sea-Sickness.

SEA-SICKNESS has been the curse of seafaring mankind since first we began to go down to the sea in ships. Like every other malady to which flesh is heir it has been the subject of much study, with a view to its prevention and cure. The task appears to] have been more or less aban-

doned by legitimate medical investigators, who are content to take what the barristers call "a watching brief" and await further scientific developments before grasping this thorny problem anew. Meanwhile sea-sickness forms a kind of Tom Tiddler's ground for inventors and others infected with the craze of curing their fellows of this, that and the other malady—for a consideration, expressed conveniently in terms of coin of the realm. If one could only believe in newspaper "cures" sea-sickness has been robbed of its terrors this hundred years and more. Yet hope lingers pathetically in the human mind, even in so apparently forlorn a case as sea-sickness. Possibly the latest "cure" may bring relief to the wave-tossed citizen. It is a steel cap, heated by electricity, to be applied to the head, and is the invention of a gentleman who bears the appropriate name of Herr Kappmeier, of Alsklosta. The idea is to correct the anæmia of the brain which is assumed to be the cause of sea-sickness. Many medical men, however, hold quite different views as to the causation of the malady. Indeed, the general misery and the violent behaviour of the stomach appear to be the only phenomena unanimously accepted by medical informed science.

Compensation for Trade Anthrax.

THE cause of public health is likely to be materially advanced by the wider application of the principle of compensation to workmen, especially in the case of the "dangerous trades." This happy result will be attained by the simple appreciation on the part of the employer of the fact that it will be cheaper in the long run to pay for prevention than for compensation. In a recent case of anthrax contracted by a Bradford operative the firm of woolcombers for whom he worked agreed to pay £140 under the Compensation Act. Although the spores of anthrax are resistant, it would not be beyond the power of sanitary science to devise some method of sterilizing the wool, or better still, of detecting infected hides and fleeces. Incidentally, the Bradford case furnished a vivid illustration of the birth-rate question among the poor. The widow had had eleven children, of whom six at least were living. One, a boy of seventeen, was paralyzed and unable to follow his occupation, a girl of fifteen was in a convalescent home suffering from phthisis, a girl aged twelve earned two shillings a week, and there were three other children, aged ten, nine, and four years respectively. In this little social drama the only sharply limited factor appears to be the wages.

Garden Cities.

THROUGH all the silly crazes of the moment which have for their ostensible object the improvement of health there may be noted one strain namely, a return from the artificial conditions of urban existence to the natural surroundings of the country. It is to the credit of the profession that it is through its influence that this healthy

reaction has taken place, though it may not be equally praiseworthy that the necessity of the change was not recognised till nearly nineteen hundred years of the Christian era had elapsed. Still, it is a distinct gain that public opinion is now awake to the fact that man is an animal who requires not only food and drink, but fresh air, sunlight, and elbow-room. The success which has attended the efforts of the promoters of the "Garden City Association" is a gratifying evidence that the laity are beginning to take a practical interest in the healthy planning and building of their towns, and gratitude is due in no small degree to Mr. Ebenezer Howard and his colleagues for demonstrating that some ideas that sound Utopian are reducible to practical realisation. It is then annoying in the extreme that certain persons have imitated the name but not the substance of the Garden City scheme, and that while seeking to attract shareholders and customers by using the term "Garden City" for their speculations, they should be so doing for their profit, and not for the benefit of their prospective tenants. The pith of the original plan is that over-crowding and high rates, those evils at the root of all city misery, are incapable of rising in the Garden City because of the system of land tenure which devotes all automatic increase in the value of the land to the benefit of the citizens themselves. Any "Garden City" that does not observe this condition is nothing more than a delusion and a snare, that is to say, so far as the first principle of the original scheme are concerned.

'Detailing.'

OUR contemporary the *Medical Record*, in its April 28th number, publishes a special article on the opportunities for the Recent Graduate, of course, in America. From it we glean much interesting information, and, generally speaking, we should say that the, public services in America seem to present advantages and opportunities for young men very similar as regards prospects and pay to those in this country. But we confess we read with some surprise that specific mention is made of a form of employment yclept "Detailing," which is happily rare in Great Britain. "Detailing" anglicised would seem to mean acting as a commercial traveller for drug, instrument and book firms, a position hardly deemed consonant with the dignity of the profession as understood over here. The detailer is assigned a territory by his employer, and in this district he is expected to beat up and canvass his brethren in buying the goods of the firm which engages him. As the detailer is usually paid by commission, it is obviously to his advantage to secure custom by every possible method, and we are told that he must, to be successful, cultivate "courtesy and tact," and that he will find the work "pleasant and fairly remunerative." Other advantages of the position are that "it gives the young physician an excellent opportunity to study manners and customs of the different pro-

fessional men with whom he is brought into contact. Whatever the detailer may learn in America, we fear that in England he would learn little from such study except the art of brevity of speech and chilliness of demeanour. We should imagine that the chief quality a detailer should possess would be a hide-bound indifference to snubs and bad words.

Medical Defence Union.

WE are glad to learn from the annual report of the Medical Defence Union that this useful and plucky body is not only continuing its good work, but that it is in a financially strong position in spite of the many calls made upon its funds. In a hundred and eighty-eight cases taken up by the Union on behalf of its members during the past year in only one was a verdict given against the member, and in that case the damages awarded were only one farthing. The law costs sustained by the Union are very heavy and form the chief outgoing, the other expenses being light, but it is the principle of the Union that every case which it takes up shall be fought irrespective of cost, and it is not therefore surprising that its expenditure under this head amounts to some £1,700. Needless to say the bulk of the litigants with whom the Union's clients are involved are men of straw, and the actual amount received from them in costs is very small. The most important case for the year landed the Union in some £400 for costs, of which it only recovered £40 from the offending party. We notice with pleasure that the name of the MEDICAL PRESS AND CIRCULAR is mentioned with gratitude by the officials of the Union for the support it has rendered to the Union, and we can only repeat what we have said before that it is incomprehensible to us how any medical man can fail to cover himself against possible ruin by not joining the Union or some similar society.

The Postmaster-General and the Press.

THE Postmaster-General last week, speaking at the annual dinner of the Newspaper Society, spoke of the happy relations that existed between his office and the Press. That indeed is the case, and though the fact may be one that in general may seem a matter for congratulation, we feel ourselves that the position is only maintained by a considerable sacrifice of principle on the part of the Post Office. Were the Postmaster-General to realise his responsibilities we fear some of his connections with the Press, which are now so happy, would be put to a severe strain. The Post Office has wide powers in dealing with indecent and fraudulent matter transmitted by post, and no doubt very happy relations might exist between that office and the purveyors of such matter if the postal officials closed their eyes to the nature of the transactions they forwarded. Mr. Buxton, in concluding his speech, wished all newspapers an increased circulation and more advertisements, but we note particularly that he made no reference

to the character of the advertisements he wished them. It cannot be that the Post Office is ignorant of the nature of the advertisements published by many periodicals, advertisements which are filthy, disgusting, and palpably fraudulent; neither can it be beyond the power of the Postmaster-General to refuse to transmit such matter. Much is done by the regulations to prevent any harm being done by sending pathological material by post, even to the point of hampering medical research, but they are administered in an elastic spirit when moral garbage alone is at stake. A new Postmaster-General has at least a chance to distinguish himself by the prohibition of such advertisements. Will he have the courage to rise to the occasion?

Sunday Observance.

A REMARKABLE gathering took place at Caxton Hall last week to discuss the question of national Sunday observance. The Archbishop of Canterbury was in the chair, and among his many supporters were people so widely separated in religious views as the President of the Free Church Council and the Chief Rabbi. The subject at issue was dealt with by the various speakers from different points of view, and although the religious aspect of Sunday was naturally much dwelt upon there was on the whole a disposition to regard the observation of Sunday as a day primarily of rest. Dr. R. Horton described Sunday as kept in England as a unique fact in the world's history, and said that the movement was not directed only to the promotion of worship, but to the maintenance of the health, welfare, and progress of the country. It is a great point gained when prominent divines are ready to deal with the question of Sunday observance in this spirit. It is of the utmost importance that the masses in losing touch with the ecclesiastical Sunday should not wander into paths which entail work for others on what should be a general holiday from work. The week's systole is as necessary for the recuperation of the energy of the country as is a stated period of sleep, or an annual vacation, and the maintenance of an occupation-free day is of primary importance to the public health. We should be most grateful to the Committee on the National Observance of Sunday if they could devise a plan which should give to the doctor that blessing which is the birth-right of every other of his Majesty's subjects.

The Taxation of Professional Incomes.

WE are glad to notice that in the terms of reference to the Parliamentary Committee on the Income Tax is included the question of the differentiation for purposes of taxation of incomes of a permanent and of a temporary character. We presume that what is meant is a distinction between incomes due to interest on property and incomes due to personal labour. This is a matter of the utmost importance to members of the medical profession, who, in common with other professional people, are at present extremely

unfairly treated in the matter of direct taxation. It is manifestly improper, from a merely economic standpoint, that any hindrance should be put in the way of personal industry, such as is done by the taxation of professional earnings. Under the present system a medical practitioner earning, say, four hundred pounds a year, has to pay exactly as much in income-tax as an idler who receives an unearned four hundred a year from ground rents. The whole question needs discussion, and an opportunity is now open to the medical profession of pressing their views. It is a matter which might well be taken up by the British Medical Association and evidence put before the Parliamentary Committee. We see, however, that although the Exeter Division has issued a memorandum on the question, the Association will not take it into consideration until July, when in all probability the Committee will have sent in its report.

PERSONAL.

PROFESSOR ELIE METCHNIKOFF will deliver three lectures at the Royal Sanitary Institute, 37, Russell Square, London, on May 25th, 28th, and 30th, at 5 p.m. The subjects are: (1) "The Hygiene of the Tissues" and (2) "Of the Alimentary Canal"; (3) "Syphilis."

DR. W. BARRIE DOW, of Dunfermline, was on the 4th inst. entertained at dinner by the Fifeshire Medical Association on the occasion of his retiring from practice. Dr. Dow, who was recently presented with the honorary degree of LL.D. in the University of St. Andrews, has been upwards of fifty years in practice.

The sixty-first annual dinner of the German Hospital, London, was presided over last week by the German Ambassador, Count Metternich, in the unavoidable absence of his Royal Highness the Duke of Connaught.

SIR WILLIAM RAMSAY has been elected President, and Sir Henry Roscoe Vice-President of the seventh International Congress of Applied Chemistry to be held next year in London.

THE directors of the Clerical, Medical and General Life Assurance Society have elected Dr. Percival Horton-Smith-Hartley, M.A., F.R.C.P., to a seat on the board, to fill the vacancy caused by the death of Dr. Lionel S. Beale, F.R.S.

DR. PHILIP HENRY MULES, M.D., the well-known surgeon, for many years ophthalmic surgeon at the Manchester Royal Eye Hospital and to the Wrexham and Altrincham Hospitals, inventor of what is now known as the "Mules' operation" for the removal of the eyeball, died on September 1st last, aged sixty-two years, and left estate of the gross value of £28,253.

HIS GRACE THE DUKE OF ARGYLL, K.G., K.T., will lay the foundation-stone of the new building of the South London Institute for the Blind at Borough Road, London, S.E., on Thursday, May 24th.

MADAME CURIE has been appointed to the vacant Chair of Chemistry at the Sorbonne, rendered vacant by the tragic death of her husband. She will be the first woman who has held a Chair in the Sorbonne.

A CLINICAL LECTURE ON TROPICAL ABSCESS OF THE LIVER.

By G. P. NEWBOLT, M.B., F.R.C.S.Eng.,

Surgeon to the Royal Southern Hospital, Liverpool, and Dean of the Clinical School.

As one of the surgeons to the Tropical Ward of this hospital one sees many cases of abscess of the liver arising from disease contracted in the Tropics, or in other words secondary to dysentery, and in all the cases I have seen a history of dysentery has been obtained. Two forms of abscess are met with, the large and usually solitary one, which lends itself to surgical treatment, and the multiple pyæmic abscesses which, as far as I know, are invariably fatal. In eight cases recently observed the amœba of dysentery was found in the scrapings from the wall of the abscess, but only once in the sloughs in the stools. The position of the patient on his back with the right thigh flexed and the body bent towards the right side was noticed several times. Pain was usually present and the peculiar yellowish tint of the skin and eyes, not exactly like jaundice, was observed more than once. Œdema of the side and back was marked in one case, and in two others the abscess was pointing through the chest wall. In some instances the liver was enlarged downwards, but generally speaking, the abscess was found towards the upper and convex surface of the organ, the tendency being for it to point towards the chest. Friction could be heard in this situation in several cases. Two patients were seen suffering from liver abscess who were going about without much discomfort, only the pulse was quicker than normal, but it is probable that early on in the disease the temperature was raised. Though when the dysentery is severe the symptoms of liver abscess may be obscured, yet the opposite may happen; and I explored one man in whom the pain caused by dysenteric ulceration was so intense that I felt sure he had a liver abscess. With regard to diagnosis, one has first to make sure of the presence of pus and then to determine the primary source of it; a definite history of dysentery helps matters, but patients often overlook slight attacks and in some cases are too ill to give any history at all.

Some cases present all the typical signs of liver abscess and cannot be mistaken, but the symptoms vary with the stage in which one sees the disease, and though acute at first the abscess may become more or less chronic and present few physical signs. The diagnosis may therefore be easy or on the other hand exceedingly difficult; and even though pus be suspected, yet it is not always easy to locate the abscess. Malignant disease of the liver, more especially if primary, as in carcinoma or more rarely melanotic sarcoma with a big tender liver and a high temperature, may easily be mistaken for acute hepatitis, and if the patient happens to come from the Tropics, or if there be a history of dysentery, the mistake is quite a natural one. Breaking-down gummata which are often attended by fever of a hectic type very much resemble liver abscesses. In malaria very often hepatitis of a non-suppurative type is present and may be mistaken, and a friend of mine had his liver explored ten or twelve times with a needle, the symptoms eventually clearing up. A suppurating hydatid is usually more tense than a liver abscess, and the history will probably point to the nature of the complaint. One recently seen was in a girl, æt. 12, who had never been abroad, she had had a lump in the region of the liver which had recently become painful, and which was drained through the chest wall. It is a fact, I believe, that abscess does not occur at this age. Empyema, especially when encysted, may be mistaken, and one must always be suspicious of a basal pneu-

monia when practising in the Tropics and on the look out for the condition described by Cantlie as the supra-hepatic abscess. I have been able to demonstrate the fact that pus comes more forcibly through the needle during inspiration when the abscess is sub-diaphragmatic, and more forcibly during expiration if the pus is above the diaphragm. One has to diagnose between rupture of a liver abscess through the diaphragm causing empyema and the perforation of a duodenal or pyloric ulcer, the contents of which have produced a sub-diaphragmatic abscess, and this has perforated the diaphragm, forming an empyema. In the first instance operation may save the patient, in the second it is hopeless. Again, a liver abscess may complicate appendicitis, and from two recent specimens which I have seen the condition can hardly be described as very rare. When the abscess has perforated the diaphragm and is being coughed up, one has to diagnose between liver abscess, empyema, hydatid and tubercle. An examination of the expectorated material may show broken-down liver cells or amœbæ, and in the absence of cysts or bacilli the diagnosis rests between liver abscess and empyema. This can be cleared up by exploratory incision. In some cases the chocolate brown viscid-like matter expectorated is quite characteristic. Amœbæ were not found in the pus from my cases, though it was examined at once, but they were usually found in the sloughs removed when dressing the patients two or three days later. In two cases examined the pus was not sterile, and it is hard to believe that it can be when secondary to dysenteric ulceration. In exploring for a liver abscess when it is likely that the needle will have to be introduced more than once, an anæsthetic is advisable, but if the patient is very ill a local anæsthetic can be used. The most important point is to use a needle large enough to draw off the thick pus which may be present, and it should be at least six inches long. I have opened all my cases freely and drained the cavity with large tubes, but if the abscess be deeply situated the use of a special trochar and cannula is advisable, this will save hæmorrhage, but there are objections in that the tube may slip out, get blocked, or may not drain sufficiently. When the abscess points towards the chest wall it is usually, but not always, necessary to remove rib. In a case recently seen the pus was so thick that it would not run through the needle, but there was a communication with the lung, and it was only after disconnecting the tubes of the aspirator that one saw pus in the needle. The latter moved freely in a cavity, the up and down movement pointed to its being in the liver. It is always well to be prepared to follow up your exploration by immediately operating if pus is found, and in exploring from the abdomen personally I prefer a preliminary incision with exposure of the liver. In one case when the needle entered the abscess cavity the tension was so great that pus escaped by the side of the needle and had I not incised the abscess, no doubt an empyema would have formed. I believe it saves time if, when operating, the walls of the cavity can be well cleaned with gauze dabs or scraped gently with a blunt lithotomy scoop. Many surgeons are opposed to this, as they say hæmorrhage occurs; this has not been so in the few cases in which I have done it. Washing out with disinfectants is useful though not by any means necessary, unless there is a high temperature, but must be avoided if there is any suspicion of a communication with the lung. The typical

anchovy sauce discharge was present in many of the cases, and in several bile-stained discharge appeared later on. When operating through the abdominal wall the liver not being adherent and pus lying deeply, it is necessary to shut off the peritoneal cavity. As a rule the surface of the liver is inflamed and the capsule will hold sutures, but in one case I had to pack with gauze and leave the patient for some days before opening the abscess. I tried stitching up his liver, but the sutures cut out. I have tried stitching the liver to the abdominal wall in the *post mortem* room, but the stitches will not hold unless one first buries a figure of 8 stitch in the liver substance, and then sews up with this as a basis. The presence of a second abscess is always to be looked for, but whether one is justified in exploring from the cavity of the first unless there are distinct signs is doubtful. It is probable that if the patient is not relieved at once by the opening of a large liver abscess there are others present, unless severe dysentery is complicating matters, but in exploring for them the puncture had better, if possible, be made in a fresh place, and not through the first wound. The few cases observed bear out the

completely curing the dysentery, which after the abscess is better is apt to be made light of.

PHOTO. II.

CASE I.—In this man three abscesses were opened during a period extending over four years, two through the chest wall, and one by laparotomy. The third abscess opened into the lung, and he was rapidly becoming exhausted by the constant cough—twenty-eight ounces of pus were coughed up in twenty-four hours. During the whole of his illness, slight dysentery

PHOTO. I.

statement that the favourite site for abscess is the upper convex surface of the liver, and that lung complication is common. In Case I. two abscesses were opened through the chest wall, and one of these communicated with the lung. In Case II. one abscess was opened through the chest wall. In Case III. two abscesses were situated at the upper and posterior surface, but were not opened. In Case IV. the abscess pointed through the chest wall. In Case VII. the abscess opened into the lung and was drained by resecting ribs, finally Case VIII. was opened through the seventh interspace.

In only one instance was the left lobe of the liver affected, and this also applies to the pyæmic cases. The method of allowing the abscess to burst through the lung as a means of cure we must hope is now obsolete, for if Cases I. and VII. had been left to Nature neither of the men would now be alive. The first man was rapidly being exhausted by his cough alone, and the second could not empty his abscess as the pus was too thick.

Prognosis.—Four out of eight cases got better, but in all these the abscess was single except in the first patient, where three were opened one after another; the pyæmic cases all died. It is probable that as long as a trace of dysentery remains the patient is liable to a fresh infection, and it is useless curing the abscess without at the same time

existed, and this was cured by injections of nitrate of silver, 20 grains to the pint of water. He made a good recovery.

CASE II.—Two abscesses were opened, one through the chest wall behind, and the second by laparotomy, a third abscess existed between the other two, but unfortunately was not detected, and the man died. His dysenteric ulcers were healing.

CASE III.—Had pyæmic abscesses, one large one was opened by laparotomy, six days later he was seized with uncontrollable vomiting and died. Two abscesses were situated at the back part of the liver.

CASE IV.—Was a good example of a man going about with an abscess of his liver without suffering much inconvenience. It was pointing below the ninth rib, which was necrosed. He made a good recovery, after resecting the diseased rib and draining the abscess.

PHOTO. III.

CASE V.—Here the only symptom was a quick pulse and a little uneasiness in the hepatic region. He had a high leucocytosis. After exposing the abscess by abdominal section the pus would not run through a big needle, and this I regard as an argument in favour of exposing the liver by laparotomy and then using the exploring needle. Recovery ensued.

PHOTO IV.

CASE VI.—Was one of multiple pyæmic abscesses in a soldier. He had been explored abroad by laparotomy, and it was thought he had a malignant liver. When admitted to the Southern Hospital it was evident that pus was present, the abscess was tympanitic. Gas escaped when it was opened. He died later on and *post mortem* there was only a thin wall between the abscess cavity and the transverse colon. The liver was full of pyæmic abscesses.

CASE VII.—Here the patient was merely skin and bone, and was expectorating the contents of his liver abscess. The expectorated material was reddish in colour, and contained liver cells. After resecting rib and draining the abscess, the pus in which would not run through the needle used, as it was of the consistency of thick cream, he made a good recovery.

CASE VIII.—Here the patient worked as a fireman until admission. His abscess was pointing through the chest wall. Photo I.—An opening was made through the seventh interspace, shown in Photo II. He, however, did not improve as his dysentery was very severe, and *post mortem* the whole of the large intestine was covered with sloughy ulcers which, in the sigmoid region, had caused adhesions to the pelvic walls. Photo III.—Though fifty ounces of pus were evacuated, ten days later the cavity would only contain four ounces of lotion. There were some infarcts in the liver substance around the abscess cavity—Photo IV.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of the journal. The lecture for next week's number will be by Professor James Alexander Lindsay, M.D., F.R.C.P. Lond., Professor of Medicine, Queen's College, Belfast, Physician to the Royal Victoria Hospital, Belfast, on "Malignant Disease of the Lungs."

A SERIOUS epidemic of measles has broken out at Sedgley. Three children who contracted the disease were allowed by the parents to attend school, with the result that other children caught the contagion, and on Saturday about 150 children were, it is estimated, directly or indirectly affected.

A TELEGRAM from Philadelphia says that 200 police and fifty physicians have isolated nine blocks in the densely populated portion of the city, forcing 14,000 persons to submit to medical examination and 3,000 to vaccination.

ORIGINAL PAPERS.

THE QUESTION OF CANCER.

By DR. DOYEN, OF PARIS.

(Read before the International Congress of Medicine, Lisbon, April, 1906, specially translated for this journal at the request of author by Mr. H. de Meic, M.R.C.S., Surgeon to the French Hospital in London.)

What scientific proof exists in the present day of the parasitic nature of neoplasms, and more especially of cancer?

Cancer, whether as an epithelial or a sarcomatous tumour, and all neoplasms, whatever their histological variety, are of parasitic nature. The pathogenic agent is the micrococcus neoformans which I described in 1901. The cancer microbe can be obtained in a pure condition from all aseptic tumours that develop rapidly, and especially from neoplastic ganglia of recent formation. Three times I have succeeded in obtaining cultures of it by inoculating mammary tumours and a sarcomatous ganglion in a bitch.

The pieces removed with strict aseptic precautions from the tumours or the ganglia should be cultivated in tubes containing a very small quantity of bouillon from the udder of a cow to which is added 0.5 per cent. of chloride of sodium and 1.2 per cent. of Chapoteaut's peptone. The development of the micrococcus neoformans is better carried out if the neoplastic fragment is bathed by the bouillon without being entirely immersed in it.

The bouillon becomes turbid sometimes in 18 or 24 hours, sometimes only in two, three, four or five days. During the first phase of the culture, isolated microbes, diplococci, triads and tetrads, come especially under observation, later on numerous chains having from five to nine elementary parts are seen, which have a tendency to bifurcate in the form of a Y. The elementary parts of the micrococcus neoformans are of a very irregular diameter; their mean diameter is 0.5 m.m., the smaller ones being 0.2 m.m., the larger 2 m.m.

In tumours and fresh cancerous juice there are but a small number of micrococci that can be coloured by Gram's method. Excellent preparations can be obtained with Azur II. Eosine and Azur II. dissolved in methylic alcohol and of glycerine according to Giemsa's formula. The lamellæ are coloured during twenty-four hours by means of a 10 per cent. solution of Giemsa's reagent (Griibler) in ordinary sterilised water and the colour is removed by water either pure or with the addition of a few drops of methylic alcohol. The lower part of the preparation remains of a blue colour and the micrococcus neoformans is shown up by a reddish purple staining. Such preparations are very difficult to bring to a successful issue.

The microbe as soon as it is developed in the bouillon can be coloured by Gram's method, though it soon loses, at least partially, the property of remaining coloured under the action of iodine. Really, in old cultures, coloured by carbolised violet and Gram's method with double colorations by weak fuscine, only a small number of cells, sometimes the halves of micrococci, can be seen having a violet colour and the red staining predominates. The micrococcus neoformans is differentiated from all other kinds previously described by its morphology, by the character of its cultures on gelose and gelatine, and by its pathogenic properties.

1. *Morphology.*—To the educated eye the young cultures containing little else but diplococci of unequal beading are characteristic. At the end of from two to three days, the Y-shaped bodies and the little chains of 5 to 9 elements can be observed, rarely anything beyond these. The mean diameter of the cells is 0.5 m.m., and may vary from 0.2 m.m. to 2.0 m.m. and even more.

2. *Characters of the Cultures on Gelose or Gelatine.*—The bouillon culture transplanted on to ordinary gelose develops as a layer having a greyish white colour, shin-

ing, very thin, and fluorescent to light by transparence. At the end of from twenty-four to forty-eight hours it is seen that the culture is adherent to the gelose and has become fixed as viscous filaments to the platinum needle. As it gets older the culture becomes almost transparent. On gelatine, with stab culture, liquefaction commences about the fourth day and rarely reaches the whole of the centre.

3. *Pathogenic Properties.*—The micrococcus neoformans presents this peculiarity—namely, that it is an intra-cellular parasite. When injected into the testicle of a guinea-pig, it penetrates into the epithelial protoplasm which plays the part of phagocytes to the parasite. By experience it is found that the testicles should be removed on the third, fourth, or fifth day and coloured by carmine and Gram's method after fixation with acid sublimate. The most characteristic lesions are obtained with white mice and white rats. The following is the technique of the inoculations:—

A certain quantity of tumour and ganglion fragments should be cultivated, 10 or 20. After from 24 to 48 hours all these cultures are transplanted on to gelatine inclined at a certain angle to find out if there is no contamination by the staphylococcus aureus and if the cultures themselves become filamentous from contact with the platinum needle. Inoculations after twenty-four hours can be made in a same number of gelatine tubes of cultures on gelose. The bouillon tubes which have remained sterile should be again inoculated on gelose the next day or the day after. On the fifth or sixth day all the original tubes corresponding to the gelose tubes that have been verified as pure are emptied into a sterilised glass; the fragments of tissues in which the cells are dead are cut into small pieces and pounded in a mortar and the whole is passed through a fine metallic sieve. The corresponding cultures on gelose rendered diluent by twenty-four hours cultures on a cow's udder bouillon are then added. Of this emulsion a quarter of a cubic centimetre should be injected into the peritoneum of a white mouse and about three cubic centimetres into the peritoneum of a white rat. It is easy to effect these manipulations in sterilised vessels, strict aseptis being employed.

For each inoculation from 25 to 30 mice and as many rats are necessary. A certain series for example may be inoculated with cultures of ovarian cancer, another series with cultures of sarcoma or of encephaloid osteosarcoma. With the emulsion of quite young microbes can be mingled cultures on gelose of microbes collected at a more ancient date such as 15 or 20 days.

Cultures, when too old, seem to lose part of their virulence. Subcutaneous inoculations are less active, but may be carried out notably in the breast of the dog. It is easy to inoculate medium sized bitches in the peritoneum, and in the breasts, but in some animals the inoculation should be preceded by an injection of a sterilised mixture of paraffin fusible at 40° C., as an irritating agent.

I will not waste time in describing two subcutaneous lipomata which developed in two months in a bitch, or two cases of arborescent lipomata of the peritoneum accompanied by generalised visceral lipomatosis which supervened in one month and two months respectively in two female mice, or some other isolated results.

A series of the most typical lesions can be studied in the white rat. One of the difficulties in these experiments is to avoid secondary infections, especially by the staphylococcus aureus with which these naturally dirty animals teem, especially on the surface of the skin and in the sebaceous hair follicles. For this reason I have made a certain number of inoculations directly into the peritoneum through a small incision in the linea alba. It is rare for any interesting lesions to appear before the end of the second month. However, in animals that have died, the first nine days, the second and the third thirteen days after inoculation, I have found a lesion of the liver characterised by an intense perihepatitis in which the cellular tissue was crowded with the micrococcus neoformans undergoing the process

of phagocytal destruction, and by miliary and nodular foci of newly-formed cells. These foci destroy the hepatic tissue and have some analogy with small sarcomatous nodules. These hepatic lesions have also been observed in rats that have died after a longer period. I will not insist, however, on the importance of this miliary lesion of the liver because it is too easily criticised by being relegated to the rank of purely inflammatory lesions.

For the same reason I leave on one side the formation in the lungs and lymphatic ganglia of the same animals of nodules analogous to the hepatic nodules described above. In reality these lesions are not sufficiently characteristic for one to affirm that the process is not merely inflammatory.

The most interesting lesions are seen in the lung from two to four months after inoculation. The animals experimented upon must be closely watched many times each day, so that they may be killed at the exact moment when they are near to death. In fact, the specimens taken several hours after death are much less reliable for demonstration. These lesions present two distinct types.

1. A partial infiltration of the lung by nuclei, presenting all the characters of hyaline cartilage.

2. A sort of reddish grey hepatitis, affecting more often the inferior lobes.

We will leave on one side the cases in which the lungs are partially transformed into caseous alveoli, as these examples correspond to accidental secondary infections.

I.—MILIARY ENCHONDROMA OF THE LUNGS.

This lesion, of which, by means of Kaiserling's method, I have been able to obtain a very curious specimen, is sometimes limited to a small portion at the edge of the inferior lobe. More often are seen at the same time a cartilaginous transformation of the edge of one, or of several lobes, and also cartilaginous miliary nuclei about the size of a millet seed disseminated on the surface of the lungs. These cartilaginous nuclei are of a bluish white colour by reflected light, and of an opaline shade when examined by transparency. The microscopical sections show that these cartilaginous transformations are preceded by an infiltration of round cells in the intercellular passages of the lung, the hyaline substance occurs at the level of these foci, which are inflammatory in appearance, and fills up one after the other the neighbouring alveoli and bronchioles. The proper tissue of the lung and the skeleton of the alveoli disappear little by little, and at those points where the cartilaginous transformation is very advanced no trace of elastic fibres can be found. These lesions, being without exception of quite recent formation, only a small number of cartilaginous capsules can be made out. It is moreover known that the cartilaginous capsules do not exist in embryonic or newly-formed cartilage. In the vicinity of these cartilaginous nuclei can be seen epithelial neoformations that seem to spring from the dilated bronchioles, although they are met with even as far as in the neighbourhood of the pleura. These epithelial neoformations present the shape of irregular alveoli covered with cylindrical or cubical cells and into whose calibre penetrates at certain points the cartilaginous substance which here infiltrates in a like manner to a colloid exudate, capable of being organised and of tending to bring about the disappearance of the last remains of lung structure. These epithelial lesions are so accentuated that some of them may be looked upon as chondroepitheliomata.

II.—EPITHELIAL NEOFORMATIONS.

The epithelial neoformations, as has just been pointed out, always coexist with the cartilaginous neoformations, but they may often be observed alone. Some pulmonary lobes invaded by the greyish red hepatitis before mentioned are riddled with large irregular cavities lined with a single layer of cylindrical epithelioma and between these the pulmonary alveoli are weakened and compressed. These newly-formed epithelial alveoli with their cylindrical coating are identical with those that may be seen in some cases of

cylindrical cancer in the human being. The pulmonary lobes thus affected are invaded by newly-formed epithelial alveoli, the invasion extending to the neighbourhood of the pleura. These epithelial neoformations take birth, without exception, in the centre of small collections of round cells analogous to those which in before mentioned cases of enchondroma are most active in the formation of hyaline substance.

In other parts the cubical epithelial covering is transformed into stratified pavement epithelium and the epithelial cells, on their road to active proliferation, are seen to have multiplied either between the epithelium of a dilated bronchus and Reissen's muscle or, after having perforated and destroyed this muscular layer, in the adjoining peribronchial space. These peribronchial nodules infiltrated with neoformed epithelial alveoli can attain such a size that the pulmonary alveoli, weakened and compressed, are found to be thrown back on their periphery and then present but a potential cavity. It is easy to follow in the microscopical section the process of these epithelial neoformations.

Two types of epithelial lesions can therefore be observed, generally in juxtaposition; large alveoli with a cylindrical covering, and small alveoli full of cubical epithelia.

GANGLIONIC METASTASES.

The lymphatic ganglia of the thorax are generally hypertrophied. In a certain number of cases, the presence of small foci, sometimes confluent, of similar cells to the cells of the peribronchial epithelial neoformations cited above can be demonstrated; these neoformations seem to be epithelial metastases infiltrating and separating the lymphatic follicles or the medullary substance.

PROPORTION OF POSITIVE INOCULATIONS.

Epithelial or cartilaginous neoformations have been observed as the result of four series of inoculations, dated respectively March 16th, May 25th, July 1st, and October 25th, 1905, on more than 50 per cent. of white rats which had survived the inoculation more than two months. Cartilaginous neoformations have been observed, in a more or less accentuated degree, on eleven animals, whilst the epithelial neoformations existed in all cases of positive inoculation; the cartilaginous neoformations have thus been superadded to the epithelial neoformations in eleven cases.

The micrococcus neoformans is then a new species of microbe well characterized—

1. By its constant presence in spontaneous tumours of rapid evolution.
2. By its mode of development in various culture media.
3. By its morphology.
4. By its property of being an intra-cellular parasite. Its inoculation on animals, notably on white mice and white rats shows:
5. That this microbe is endowed with unquestionable pathogenic properties and that its inoculation provokes in a large number of the animals experimented upon neoformations of a conjunctive type (chondromata) or of an epithelial type identical with certain spontaneous neoplastic lesions of man and of animals.

These experiments necessitate great perseverance and require a very careful technique. The results, of which a description has just been given, are the fruit of five years' uninterrupted researches. Those of my colleagues who would desire to repeat them must multiply the number of cultures and inoculations so as to have more occasions of finding cultures not only very virulent but also endowed with accentuated pathogenic properties.

The organs of small animals should be collected immediately after death, cut up with the microtome into sections which should each be numbered and placed in a series, so that no particularity worthy of interest can possibly be passed over.

ETIOLOGY OF NEOPLASMS.

To discover in the most varied neoplasms having the conjunctive or epithelial type, a constant parasite,

should suffice by itself to establish a probable etiological relation between the tumour and the parasite.

It has just been seen that experiments on animals, notably on the white rat, have given results not only positive, but also sufficient to establish and characterise the pathogenic role of the micrococcus neoformans as well with regard to neoplasms of the conjunctive type (lipomata enchondromata) as to epithelial neoplasms (alveolar and cylindrical cancer).

The process that presides at the development of tumours is very simple; the pathogenic microbe is very abundant in nature; it can develop as well on the surface of the skin and mucous membrane as in the buccal cavity and in the digestive tract. The portal of entry is most often a fissure of the skin or mucous membrane, an erosion caused by a carious tooth, an old ulcer of the stomach, a fistulous track. The micrococcus neoformans can also penetrate through the excreting canal into the acini of the breast, of the pancreas.

Next to direct infection, which is generally the cause in epithelial cancers, infection by the vascular or embolic road produces in its turn nearly the totality of tumours of mesodermic origin and some epithelial cancers, for example, cancers of the thyroid body, of the kidney, of the ovary.

The micrococcus neoformans, an intra-cellular parasite, determines the proliferation of the epithelial and mesodermic cells into the protoplasm from which it has been introduced and in which it partially undergoes phagocytic destruction. The irritated cells proliferate and multiply whilst deviating at the same time more or less from their original type. It is an accumulation of neoformate cells that, through the tendency of these last to grow and to invade adjoining tissues, constitutes, according to their more or less penetrating and destructive evolution, benign and malignant tumours.

Slowly progressing tumours and those of a benign character are the seats of a latent microbism and are susceptible, on the slightest occasion, notably under the influence of a traumatism, of undergoing malignant transformation. An adenoma of the breast can develop, as well as an osteo-sarcoma of the limbs, after a violent blow, which acts as a fixator of the pathological process in the same way, for example, as in osteo-myelitis of young people. As soon as the neoplastic process is installed, all the parasitic cells are susceptible of contributing to the formation of the tumour. It is thus that in the production of epithelial tumours there is always neoformation of conjunctive tissue, and this last may even predominate in certain metastases in which the epithelia are rare and are, as it were, smothered by the neoformate fibrous tissue.

Mixed tumours and all the different varieties produced by a distant infection are equally explained by the fact that all parasitic cells are susceptible, when carried away in the lymphatic or sanguineous current, of proceeding a long distance to proliferate and form a secondary tumour, in the same manner as the development of the parasite outside those cells can infect the neighbouring cells, which in their turn become the point of departure of lesions superadded to the first.

Thus, I have observed in a sub-maxillary gland metastases of epithelioma, of the epidermic globus variety, coming from the tongue, whilst by direct contact the acini had been transformed into cylindrical cancer.

The neoplastic process is nothing more than a special inflammation in which the parasitic cells have the property of multiplying themselves *ad infinitum* and of invading the human organism either from near to near or by metastases until death is caused.

DR. GEO. R. ADCOCK, of Pimlico, said to be legally qualified, but whose name we cannot find in the "Register," was committed for trial at the Westminster Police court on Saturday last, bail being refused, in connection with the so-called "Christian Scientists" and the recent death of Major Whyte.

INGUINAL HERNIA IN A FEMALE.*

By E. SCOTT CARMICHAEL, M.B., F.R.C.S.E.,
Assistant Surgeon, Edinburgh Royal Hospital for Sick Children, &c.

In adults this form of hernia occurs in the female in from 5 to 10 per cent. of all cases, and in children the proportion is higher—just over 10 per cent. of 760 radical cures performed in the Sick Children's Hospital. In the majority of cases the rupture is noticed within the first few years of life, and is probably of congenital origin. As in the male, the hernia is more commonly right than left sided; in the series quoted 39 were right, 24 left, and 13 double. Contents were found lying in the sac in 28 cases, the relative proportions being as follow:—Tube and ovary, 17; tube alone, 5; small intestine, 2; omentum, 2; cæcum, ovary and tube, 1; appendix and ovary, 1. In two cases the sac contained a tuberculous nodule.

Hernia of the Ovary and Tube.—It is suggested that the persistence of the so-called canal of Nuck should be associated in so large a proportion of cases with malposition of the ovary and tube. In the young child the ovary may lie alongside the lumbar vertebræ on the psoas muscle as high as the lower angle of the kidney, or it may be as low as the internal abdominal ring. It is difficult to say how far the descent of the ovary depends on the action of the gubernaculum, or inguinal ligament, but probably this band is in some way responsible for the position of the organ. The tube and ovary were present in the sac alone or along with another viscus in 24 out of 28 cases, and this frequency cannot be explained on mechanical grounds, but must be associated with the development of the inguinal ligament. The origin of the canal of Nuck is disputed, but Mr. Carmichael was inclined, after operating on this series of cases, to regard it as an abnormal protrusion, associated in some way with the development of the inguinal ligament and caused by the same conditions as draw down the ovary and tube. These viscera do not lie free in the sac as intestine does, but are closely associated with its wall, one broad ligament or meso-salpinx springing directly from its posterior aspect. The ovary is rarely present when the canal is short, and almost invariably present when the canal is long. There is no evidence that ovarian hernia results from elongation of the meso-salpinx or mesovarium; in Mr. Carmichael's cases the mesenteric attachments were often so short as to render replacement a matter of some difficulty, and to require division of the structures. The tendency to bilateral inguinal hernia is greatest in young infants; thus, in babies under 1 year (21 cases), 8 were double; under 3 years (21 cases), 2 were double; over 3 years (34 cases), 3 were double. Similarly the younger the patient the more frequently are tube and ovary found in the sac—13 cases under 1 year, 7 cases under 5 years, 2 cases over 5 years. In order to replace the viscera it is necessary to divide the attachments freely, and the question arises as to whether the ovary should be removed to prevent future trouble. From an examination of the ovaries *post mortem*, in a number of young infants, Mr. Carmichael had satisfied himself that their macroscopic appearance varied so greatly in different instances that he had never felt justified

in removing a herniated ovary as abnormal. In adults the ovary had in some cases been found to be diseased, but in many instances there was evidence of its functional activity (swelling and tenderness during menstruation), hence it was not good practice to remove the organ as a matter of routine. In the adult there are often associated mal-development of the genital organs and sterility is the rule in double herniæ.

Hernia of the Uterus has been recorded, but Mr. Carmichael had no instance of it in his cases, though in one on traction on the tube the uterine horn appeared at the inguinal ring. Pregnancy has been observed in a herniated uterus; the organ is often malformed, and the rupture is generally left-sided.

Hernia of the Bowel and Omentum.—As the hernia is most frequently right-sided the appendix is a common content of the sac. When small intestine is present, it is usually the ileum, just above the cæcum, which prolapses. The omentum alone occurred in the sac in two cases.

Tuberculosis of the Sac.—This occurs in about 3 per cent. of herniæ in young subjects. It generally takes the form of a nodule at the apex of the sac, and in this case simulates an ovary. These nodules are simply isolated numbers of the nodules lining the abdominal cavity, for tubercle of the sac of a hernia is almost invariably associated with tuberculous peritonitis. Hence, when an oval swelling is detected in a rupture the examination of the abdomen for evidences of tubercle there is imperative. In the second, and less favourable, variety, the sac is thickened and converted into tuberculous granulation tissue. Examination of the abdomen reveals no abnormality, and there is little, if any, glandular enlargement. Mr. Carmichael reported a case of this nature in which operation was followed in six weeks' time by death from tuberculous meningitis. In these cases the abdominal peritoneum may be wholly converted into tuberculous granulation tissue, which may give no clinical evidence of its presence, even on examination under a general anæsthetic.

Clinical Features and Differential Diagnosis of Inguinal Herniæ.—Where a swelling is present in the inguinal region in a female subject, there are several possibilities in the matter of diagnosis. When the sac contains bowel the diagnosis is usually easy. When only a slight swelling containing an oval bean-like mass is felt we may have to do with (1) a superficial gland, (2) the ovary in the sac, (3) omentum in the sac, (4) encysted hydrocele of the canal of Nuck, (5) a tuberculous nodule in the sac. The ovary is generally mobile and can be displaced up into the canal; a gland is but slightly mobile; encysted hydrocele is also but slightly mobile, and is as well a rare condition. A tuberculous nodule is mobile and is situated at the apex of the sac, and there is generally also evidence of tuberculous peritonitis. Omental hernia is, as a rule, irreducible; it is rare in the child. The writer's conclusions are:—(1) Inguinal hernia in the female child occurs in about 10 per cent. of all cases; (2) it is associated in nearly 30 per cent. of cases with descent of the ovary and tube; (3) the presence of these organs is often associated with malformation and defects of the genital organs; (4) the condition most likely to be confused with hernia of the ovary is a tuberculous nodule of the sac.

* Abstract of Paper read before the Medico-Chirurgical Society of Edinburgh, May 2nd, 1906.

THE OUT-PATIENTS' ROOM.

FRENCH HOSPITAL AND DISPENSARY.
BY DR. LOUIS VINTRAS, M.D.

DR. VINTRAS said he would illustrate the minor philosophy of medicine by some cases in this department taken haphazard. How small injuries became of importance was illustrated by the case of a young man who had had a cut over the terminal joint of the forefinger of the left hand some time previously: the cut had been neglected and had suppurated, involving the joint; the wound was now perfectly healed, but the result was a stiff joint. This might seem trivial enough considering it was the left hand that was implicated, but it happened that the patient was a worker in metals; he used the thumb and forefinger of the left hand to steady the stiletto on which he hammers with the right hand. The fact of the terminal joint being stiff rendered it impossible for him to hold with any command the instrument in question, and therefore, like Othello, his occupation was gone. The man was much distressed, and the question was naturally of vital importance to him; he was ready to undergo any treatment or operation which would enable him to work again. It was ascertained that he could get command of his instrument by holding it between the thumb and the middle of the forefinger if the rigid end were not in his way. The treatment became obvious—the removal of the terminal phalanx. The treatment was accepted, and the result was quite satisfactory to the man. There is a certain knack, Dr. Vintras said, in seeing cases in the out-patient room, which is only acquired by long experience. For instance, two children coming from widely distant districts of London were brought in one after the other. Both were suffering from a very slight papular rash, with no temperature; there was no fever, no history beyond the sudden appearance of the rash the day before. Child No. 1 had a clean tongue and the mother said that its appetite was not impaired; child No. 2, had a tongue that was slightly furred, and it was noticed that its eyes were watering slightly; No. 1 was suffering only from a slight heat rash; No. 2 had measles and was notified by the R.M.O. The diagnosis was confirmed when, on the next visiting day, the first child was brought back quite well, while it was afterwards ascertained that the No. 2 child had a severe attack of measles. The out-patient department, Dr. Vintras remarked, is not without its tragedy. A woman, *æt.* 45, came bringing a letter from a local practitioner. She had been suffering for three weeks with incessant vomiting, with pain over the epigastrium. The vomiting had somewhat abated during the last three or four days, and she was able to keep food; she was a cook in a situation, and it had been thought that with some further treatment in hospital and rest at the Convalescent Home she might make a good recovery. She was put on the couch and the region of the stomach examined, with the result that towards the right end of the stomach on deep pressure a hard nodule was discovered. On calling her attention to this she said she had lately noticed it at times, but that it disappeared at others. On questioning her closely, it was found that she had lost flesh considerably during the last three months, and that what she had been vomiting had often been of a dark brown colour, and at other times tinged with blood; her breath smelt very bad. The surmise, of course, was carcinoma of the stomach. The supposed disappearance of the hardness of which she had spoken had been merely caused by the fact that when the stomach was dilated with wind, the nodule was pushed upwards and at other times it receded. The woman was admitted to the hospital; her condition appeared to improve, and she was sent to the Convalescent Home. As soon as she arrived there the vomiting began again; it had the typical coffee ground appearance, and the diagnosis was confirmed. Here is a woman who, when she came into the out-patient department, was under the impression that she was suffering from nothing worse than a transient gastric trouble. The examples, Dr. Vintras said, might be

multiplied *ad infinitum*, but the few he had given were enough to illustrate the variety and interest of everyday practice in the out-patient department.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

REMOVAL OF A CALCULUS OF THE BLADDER BY THE SUPRA-PUBIC METHOD.—MR. PRYTON BEALE operated on a man, *æt.* about 40, who had been previously sounded, a stone being detected in the bladder. The stone was computed to be about an inch and a-quarter in length, with a smooth surface, and it had given rise to very few symptoms, pain along the urethra after micturition being practically the only one. The presence of this stone was only detected in the routine examination of the case, that is to say, the urine was examined, the abdomen was palpated with a view of feeling the kidneys, the rectum was investigated, and lastly, the bladder was sounded, when the presence of a stone came rather as a surprise. The patient had a slight stricture of the membranous urethra, and although the lithotrite might have been introduced it would have been difficult or impossible to pass an evacuator. Thus supra-pubic cystotomy was decided upon. The operation was performed in the ordinary way, no difficulties being encountered. The stone was a flat one, measuring about an inch and a-half by an inch and a-quarter and three quarters of an inch thick. Mr. Beale remarked that this was an example of a case in which a stone was found, as it were, by accident. He considered that it was not wise to attempt lithotripsy where there was the slightest indication of a stricture, because, although the lithotrite might be introduced fairly easily, the passing of the evacuator might give a great deal of trouble; moreover, the crushing of a stone would be working in the dark, and in these days he ventured to think that the average surgeon had such a very slight experience of lithotripsy that he was hardly justified in undertaking it except for quite small stones. Supra-pubic cystotomy, he remarked, was so extremely simple that it was on the whole safer. He had had a case some years ago in which the stone was detected by a sound passed at the time of operation, but on opening the bladder supra-pubically no stone could be found. This turned out to be a case of hour-glass bladder, and the upper part of the viscus, which had been opened, was sewn up again without any removal being attempted. This patient was suffering rather severely from the stone in his bladder; but the operation, curiously enough, seemed to relieve him immensely, and at the present time, though the stone is still present, he has practically no symptoms; when symptoms do come on the stone will be removed by median perineal section.

STRANGULATED VENTRAL HERNIA IN A WOMAN

ÆT. 80.—The same surgeon operated on a woman *æt.* 80 who had suffered for more than twenty years with a large ventral hernia which had suddenly become strangulated about thirty-six hours previously. When the sac of the hernia was opened it was found to contain omentum and small intestine. Part of the latter was so doubtful in aspect with regard to its recovery that it was left just beneath the wound. However, it recovered completely and the patient progressed perfectly well. The chief difficulty with ventral hernia in Mr. Beale's experience was the presence of numerous adhesions between the omentum and the sac, but particularly in the inner aspect of the neck of the sac; he believed that it was not wise to attempt to separate these, but that the best plan was to cut off the sac at the neck and stitch the edges firmly together, leaving the adhesions intact. Of course, this could not be done if there was

any bowel of doubtful colour within the sac; if such were found to be the case he thought the best thing to do was merely to relieve strangulation at the time and then afterwards to remove the sac and stitch up the abdominal wall at a second operation. He had come across several large ventral hernia which contained the whole of the transverse colon together with small intestine. In most cases, he pointed out, it seemed that

it was the colon which suffered from strangulation. In one case he found the whole of the transverse colon absolutely gangrenous. This was merely opened freely and then at a subsequent operation the ends of the colon were approximated and dropped back in the abdomen. He was sure it was never wise to attempt an anastomosis at the time one operated on a strangulated hernia.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD MAY 11TH, 1906.

The President, Mr. CLUTTON, in the Chair.

CYSTIC TUMOUR OF THE SPERMATIC CORD.

MR. CUTHBERT WALLACE described a case of cystic tumour of the spermatic cord. A man, *æt.* 41, was admitted into St. Thomas's Hospital, with what appeared to be an irreducible inguinal hernia and gave a history of abdominal pain and vomiting. Operation showed that the tumour consisted of two main cysts with numerous smaller ones, the whole mass lying under the cremaster muscle and in the cord. At the internal ring the tumour disappeared within the abdomen and could be felt to form a considerable mass in the pelvis. The inguinal mass was excised. This case evidently belonged to those that were described by the older writers as "Diffuse hydrocele of the cord." Percival Pott, in 1773, was the first to describe the condition; he was of the opinion that it was of the nature of an oedema, and this view is the one still put forward in the English books which make mention of the subject. Mr. Wallace believed that this explanation could not be accepted. The so-called cystic adenomata of the testis and kidney were supposed to arise in remains of the Wolffian body and in their construction were very similar to the tumour under discussion. When the original relation of the testis and kidney was borne in mind it seemed that it would not be unlikely that the foetal remains found in these two organs should also be found in the spermatic cord. It appeared, then, that it was not improbable that the multilocular cystic tumour of the spermatic cord had a similar origin.

Mr. E. PERCY PATON had had a similar case four or five years ago in a woman, *æt.* 40. It was lined by endothelium. Clinically the case was diagnosed as one of hernia.

Mr. KELLOCK asked for a description of the fluid contents. He pointed out the resemblance between the condition and that found in the neck and called cystic hygroma.

Mr. H. H. CLUTTON referred to a case similar to that of Mr. Wallace's. The resemblance of the condition to cystic hygroma of the neck was only a superficial one. The walls of the cord tumours were very thin, and of quite different structure from that of a hygroma.

Mr. WALLACE, in reply, said that the fluid in the cysts was albuminous and contained no spermatazoa.

Mr. A. C. HUDSON read a paper on

CARCINOMA OF THE THYROID GLAND.

A description was given of eight cases of tumour exhibiting the characters of malignant invasion, and of six cases in which, although the ordinary clinical features of malignant disease were absent, the tumours showed the histological structure of carcinoma. Two tumours discovered at necropsy were also described. A brief reference was then made to the mode of origin of the capsule of the simple adenomatous thyroid tumour, and its possible significance in the study of the behaviour of carcinomata. The cases described pointed to the disease being somewhat commoner and at the same

time more amenable to surgical treatment than was perhaps generally believed; they also emphasised the difficulty likely to be experienced in correctly estimating the degree of malignancy of epithelial thyroid tumours solely from the type and arrangement of the epithelial cells. Evidence of metastasis and invasion of surrounding tissues was most important.

Mr. H. H. CLUTTON related the history of several cases that had been under his care. In his opinion the prognosis as regards life was considerably better than was usually thought. His first case—operated on in 1886—was still well. In diagnosis he attached importance to a high degree of fixity of the tumour to the trachea. These carcinomatous tumours were frequently overlooked, being mistaken for simple adenomata. He thought that thyroid metastases were rare.

Mr. C. W. WIRGMAN said that, on the contrary, there was a large literature of cases of such metastases. They usually occurred in the vascular bones, the skull or spine. Such growths may be the first symptoms to the patient, who might be unaware of the thyroid tumour. He had seen two such cases recently.

Mr. WALTER C. SPENCER pointed out that, in thyroid tumours, a perfect gradation might be traced between simple adenoma and the most malignant carcinoma. This applied to the metastatic growths as well as to the primary one.

Mr. HUDSON, in reply, said that the question of malignancy, and also of metastatic growths, in these cases might possibly be one of tissue resistance. In other words an apparently benign growth might invade the neighbouring structures in a malignant way if the patient was in a low state of health.

Mr. E. W. ROUGHTON narrated a case of

PERFORATED GASTRIC ULCER TREATED BY EVISCERATION AND IRRIGATION—RECOVERY.

A woman, *æt.* 26, had indigestion for three weeks, followed by symptoms of perforation. The abdomen was opened five and a half hours later and the perforation closed by sutures. As the stomach contents had escaped freely, soiling all parts of the peritoneum the small intestines were turned out and the abdominal cavity thoroughly irrigated. The irrigation was commenced in Douglas's pouch, so that the lotion might flow in the opposite direction to the extravasated stomach contents, thus minimising the risk of spreading the infection. The operation caused very little shock, and the patient made a good recovery.

Mr. W. G. SPENCER said that his objection to evisceration was not due to the shock that might be produced so much as to the fact that the procedure increased tympanites, which not only made it hard to return the intestines, but put an increased strain on the sutures. This was particularly so in the later cases.

Mr. JOHN D. MALCOLM narrated a case of COMPLETE REMOVAL OF A MULTILOCULAR CYST OF THE PANCREAS: COL-COLIC ANASTOMOSIS SIXTEEN DAYS LATER—RECOVERY.

The patient was a woman, *æt.* 50; malignant growth of the left kidney was diagnosed, but a multilocular cyst of the tail of the pancreas was found on operation, and removed. Healing caused no trouble, but symptoms of a partial obstruction of the intestine developed and the abdomen was re-opened on the sixteenth day

after the operation. The difficulty was at the splenic flexure, and was removed by forming an anastomosis between the transverse and descending colons after which there were no further urgent symptoms. The tumour, which is preserved in the Royal College of Surgeons Museum, was exhibited. It is a multilocular cystoma with a small amount of solid structure between the cysts. The fluid was not examined. The solid growth, described by Mr. Shattock, showed in parts an adenomatous and in parts a carcinomatous structure. Some of the proper glandular tissue suggested that of the pancreas. Another case (*Med. Soc. Trans.*, vol. XXI., p. 97) in which a similar tumour was removed by Mr. Malcolm was referred to; and one published (*Path. Trans.*, vol. LIV., p. 354) by Mr. Watkins Pitchford; also one recorded (*The Amer. Journ. of the Medical Sciences*, New Series 120, p. 184) by Dr. Reginald H. Fitz and eight cases collected by him—all those of "benign" multilocular cysts of pancreatic origin which he could find, but some of which showed no new growth. A case published by Dr. F. H. Dunning (*Amer. Journ. of Obstetrics*, 1905, p. 101) resembled the one now recorded in many details. The rarity of these tumours was noted, the two removed by the author and that from the case recorded by Mr. Watkins Pitchford being the only specimens in the Royal College of Surgeons Museum. The question of their origin was touched upon, and Professor Ambrose Monprofit's (*Gaz. Med. de Paris*, March 12th, 1904) case, in which it was necessary to remove the tail of the pancreas and the spleen to complete the operation, was referred to. The tumour in this case was said to arise from the remains of the Wolffian body because of its structure. On the same grounds many of the foregoing cases were attributed to the pancreas as the seat of their development, the author's first case containing fluid which was strongly amyolytic and the structure of the second very suggestive of that of the pancreas. The difficulty of diagnosis was also mentioned, most of the cases being regarded as renal or ovarian before operation. Complete removal was held to be the only rational treatment when it was possible, as drainage of a multilocular cystoma, especially if it should be malignant, was a futile procedure.

Mr. CLUTTON related a similar case that he had operated on some years ago. He had been forced to cut through the pancreas, thus causing a troublesome pancreatic fistula. Perhaps subsequent adhesions might owe their origin to the irritation of the fluid then secreted.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD MAY 2ND, 1906.

Dr. W. S. GREENFIELD, Vice-President, in the Chair.

MR. ALEXIS THOMSON showed a patient, æt. 60, suffering from chronic jaundice and distended bladder, with relief of symptoms after cholecystenterostomy. The case was interesting, inasmuch as it was an exception to Courvoisier's law. Courvoisier had laid it down as an axiom, and clinical experience had confirmed this, that when chronic jaundice was accompanied by a distended bladder it was not due to gall stones but probably to malignant disease. In the case in point the jaundice had lasted for five weeks and the gall bladder was much distended. Despite the unfavourable prognosis, an exploratory operation was performed, and about a pint of inspissated bile was withdrawn from the gall bladder; an anastomosis between the gall bladder and hepatic flexure was made, and the jaundice gradually disappeared, while bile was passed in the stools. For a time the patient went down hill, became emaciated, and a bed sore formed, and it was thought that he was dying from deep-seated malignant disease. Without any evident reason, however, improvement set in, and

now the patient was perfectly well. After leaving hospital, and while he seemed to be becoming worse daily, he began to take the glucoside of violets; whether this had anything to do with relieving him was uncertain. The lesion was probably a chronic inflammatory swelling of the head of the pancreas.

Mr. J. M. COTTERILL showed an aneurismal varix of the orbit, following an injury from a driving accident. The right eye was proptosed and the vision defective, while in the orbit a pulsatile thrill could be felt and a murmur heard. The aneurism was associated with the ophthalmic artery. The treatment proposed was ligature of the common carotid. Mr. Cotterill also showed a patient after operation for injury of the internal semilunar cartilage. It was commonly advised that in these cases the whole cartilage should be removed, but the speaker thought that it was quite enough to excise the piece of cartilage which had been split off, and to leave the remainder. He strongly advised a vertical, instead of the usual transverse, incision, as impairing the function of the joint less and not interfering with the integrity of the ligaments to the same extent. The process of treating was shorter when a vertical than when a transverse incision was employed.

Drs. ALEXIS THOMSON and WOODWARD gave a demonstration of Klapp's system of exercises for the treatment of scoliosis, which appeared to be the most rational yet introduced. They aimed at increasing the lateral mobility of the spine, and in strengthening its muscles, and took advantage of the fact that in four legged progression the spine curves first to the one side then to the other. The movements may be briefly enumerated as (1) creeping slowly on the hands and knees; (2) creeping on the hands and knees and bending the head laterally; (3) the same, but at each step forward looking back over the shoulder, first on one side, and then on the other; (4) a complicated creeping movement, consisting in crossing the limbs at each step forward.

Mr. L. C. PEEL RITCHIE showed (1) a new aluminium ligature winder, and (2) a portable rheostat for use with Kirstein's lamp for endoscopic examination, &c., and a special mirror for the lamp for purposes of demonstration.

Mr. COTTERILL showed (1) large hydronephrotic kidney and (2) hydatid cyst from the liver.

Dr. W. ROBERTSON read a paper entitled the

PRACTICAL SIDE OF AN INFANTS' MILK DEPOT.

He prefaced his paper by saying that a milk depot for the supply of sterilised milk was only an expedient rendered necessary until such time as the ideal milk supply was obtained. As to the present day milk traffic the obstacles thrown in the way of a medical officer of health in trying to improve matters were many and great. In towns the dairyman preferred to keep his cows in byres and sheds, while the scrupulous cleanliness which ought to be observed was almost impossible of attainment. Then again there was the great difficulty of securing convictions for adulteration with water, this, in Midlothian at least, was notorious. He narrated an instance of a diphtheria epidemic which was traced to a dairy in which several of the cows were found to be suffering from an eruption on the udder, and in which notwithstanding injunctions to the contrary, the milk from these animals was sold with that of the rest until a sanitary inspector was set to watch at every milking hour and personally see that the milk was thrown away. Dairyman as a class knew quite well what precautions ought to be taken; their technical journals gave them all the latest information, and until the public insisted on being supplied with clean milk in closed bottles, instead of from a pitcher which was opened fifty times in the streets, and was constantly in the way of being contaminated by all manner of dirt, the dairyman would go on in his present way. The reduction of infantile mortality from diarrhoeal disease and from malnutrition could be brought about, first and foremost, if breast feeding became more common; secondly, they had such agencies as the milk

depot. But in dealing with the ignorant classes, no matter how good the milk supplied, the ways in which it could be contaminated after leaving the depot were innumerable. He instanced such things as opening bottles and mixing one feed with another, keeping opened bottles incubating in the oven, mixing other foods with the milk, putting long tubes on the bottles instead of using the teat, &c. To prevent these, and to give the mothers instructions on feeding infants, a lady-visitor was employed by the Leith Corporation. One of the difficulties connected with a corporation milk depot was the securing of efficient medical supervision of the infants. This was a matter which ought to be undertaken by an expert, and did not fall within the province of the medical officer. In organising a milk depot the first thing was to ensure a supply of clean milk, and he had been fortunate in discovering a dairy farm from which milk containing only about 12,000 micro-organisms per c.c. could be supplied. As was known, this was a low number, and in ordinary milk there were often 250,000 or more. The milk was then pasteurised, and diluted, and had cream and sugar added in definite proportions, and was distributed in bottles containing enough for one feed. These were sent out in baskets holding 7 or 9—one day's supply, and a week's milk for an infant was charged at the rate of 1s. 6d. When the depot was first started the milk was sterilised, but there had been two cases of scurvy, and in consequence, pasteurisation had been adopted. The result of the depot had, on the whole, been extremely satisfactory.

Dr. LESLIE MACKENZIE spoke of the economic aspect of the question. Eighteen-pence a week was a sum which could not be paid by the very poor. He emphasised the fact that improvement in the milk supply would speedily follow a public demand for clean milk. He also alluded to an experiment which had been tried in Paris to increase maternal nursing—namely, the giving of free meals to nursing mothers.

Dr. JAMES CARMICHAEL spoke of the neglect of infant feeding by practitioners. Drs. Anderson, Robertson, Malcolm Campbell, and others also discussed the paper.

Mr. E. SCOTT CARMICHAEL read a paper on "Inguinal Hernia in the Female," which will be found on page 523.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, MAY 3RD, 1906.

MR. FRANK T. PAUL, F.R.C.S., President, in the Chair.

Dr. W. BLAIR BELL read a preliminary note on a NEW THEORY OF FEMALE GENITAL ACTIVITY. He argued that the uterus had a further function beyond the one usually attributed to it, viz., the secretion of an active agent which he called "uterin." He pointed out how clinical facts such as the results of complete hysterectomy, the results of complete oophorectomy, the condition of the uterus in superinvolution and the results obtained by conservation of the endometrium in supra-vaginal hysterectomy all supported his contention that the theory of ovarian secretion was inconclusive and insufficient, and that the secretion of "uterin" as an internal secretion was paramount in genital activity. He indicated the general effects of excess and deficiency of "uterin" in women. He believed that menstruation was the result of excretion of an excess of "uterin," and he thought it probable that ovulation was influenced by "uterin" circulating in the blood. The menopause was produced by atrophy of the uterus and consequent deficiency of "uterin." Dr. Blair Bell further gave an account of the methods of investigation, and laid stress on the marked effects obtained by the administration of an extract of the uterine glands.

Prof. B. MOORE having spoken, Dr. H. BRIGGS said that all the clinical statements made by Dr. Blair Bell had been well known in gynaecological clinics for

many years. As to the function of the glands of the uterine mucous membrane there was room for doubt. The great difficulty was to obtain reliable tests: catamenial and other hæmorrhages occurred under the most opposite physical conditions of the uterine mucosa.

Dr. T. R. BRADSHAW and Dr. E. E. GLYNN contributed a paper on

THE SIGNIFICANCE OF THE OPSONIC POWER OF THE BLOOD AND THE VALUE OF ESTIMATIONS OF THE OPSONIC INDEX IN THE DIAGNOSIS AND TREATMENT OF TUBERCULOUS AND OTHER INFECTIONS.

They said that in the subjects of infections attended with symptoms of general intoxication there was a tendency to produce immunity which, given a healthy organism and not too severe an infection, led to recovery. In local infections without constitutional disturbance there was but little tendency to the production of immunity. This was due to the fact that owing to the absence of toxins the immunising mechanism was not aroused to activity. To cure a local infection the right method was to imitate Nature by introducing toxins in suitable doses into the system so as to excite the immunising processes. The opsonic properties of the blood were explained and the technique employed by Wright and Douglas described. The authors confirmed from their own observations the statements of others that in normal persons the tuberculo-opsonic index is practically uniform, and that in local tuberculosis it is generally depressed. The results of treatment in their hands had been most encouraging, but they had not employed it long enough to expect any complete recoveries. They laid great stress on the importance of watching the index during the treatment as the only means by which the danger of over-dosing could be avoided. They had made observations on nine persons who had undergone the serum treatment for diphtheria, and found that in all the cases the tuberculo-opsonic index was below normal. The same was noted in a medical man who had a prophylactic dose of anti-tetanic serum.

Dr. G. E. LOVEDAY related his very favourable experience of Wright's methods in the treatment of local tuberculous and other infections.

Dr. G. STOPFORD TAYLOR said that he had obtained excellent results with Wright's vaccines in two cases of coccogenic sycosis and one of boils.

Dr. R. J. M. BUCHANAN said that in pulmonary tuberculosis the initial attack was, although it might be overlooked, always acute, the result depending largely upon the dosage of bacilli and the opsonic response of the blood. In chronic cases the opsonic content of the blood remained low, and by raising it with tuberculin injections, and judiciously exercising the patient, the prospect of recovery was increased. After inoculation it was desirable that the patient should rest from 24 to 72 hours to prevent any possible injurious effect during the negative phase arising from added auto-inoculation by exercise. People varied very much in their susceptibility to tuberculin. The negative phase occurred in experiments with bacilli and blood in hang-drop cultivations. Dr. Buchanan had observed this when working with typhoid bacilli and leucæmic blood as long as eight years ago. As a diagnostic agent, the estimation of the opsonic index should be done several times, as by a single observation the negative phase of an auto-inoculation might be incorrectly accepted as a persisting low index. Several cases of phthisis were related in which benefit followed treatment, and one in which all symptoms, physical signs and large masses of axillary glands had disappeared. The use of T.B. was followed not only by constitutional changes, but also by marked alteration in the physical signs. As a proof of local action in pulmonary phthisis he observed that in chronic cases prior to inoculation the bacilli were extra-cellular, while after inoculations phagocytosis were to be seen. He pointed out that possibly watching the phagocytic index in the sputum might be used as a general guide for inoculation. In acute phthisis phagocytosis in the sputum was common. He held that tuberculin

treatment in selected cases should be practised in conjunction with sanatorium methods.

Sir JAMES BARR related the case of a young lady who had been under the care of Dr. Blair Bell and himself. She was suffering from infective endocarditis of a very severe type due to streptococcal infection. A rigor occurred every 24 hours or oftener, during which the temperature ran up to 104° or 105°, and was followed by profuse sweating. There was an attack of pleurisy with pleuro-pericardial friction, but without any marked effusion. All the various brands of anti-streptococcal serum had been tried without much benefit. The assistance of Prof. A. E. Wright and Captain S. R. Douglas was obtained, and a vaccine was made from the streptococci obtained from the patient's own blood. Captain Douglas estimated her opsonic power twice daily, and by him the injection of the vaccine was regulated. Eventually the lady made an excellent recovery, and, with the exception of the effects of phlebitis of the left lower limb, she was now quite well. Sir James Barr attributed the success of the case to the vaccine, and he paid a high compliment to the dexterity and manipulative skill of Captain Douglas.

Dr. W. B. WARRINGTON alluded to the statement of Prof. Wright endorsed by Dr. Bradshaw that local lesions did not tend to spontaneous recovery. Dr. Warrington asked whether the tendency to local tuberculous lesions of the lungs and vertebræ was not notably towards recovery. It had been stated that though marked improvement might be noted in early phthisis, yet the opsonic index remained low. Dr. Grace-Calvert asserted the contrary. These statements required verification. Assuming that the index was increased by general treatment, should tuberculin be administered? Many, no doubt, would feel a difficulty in accepting the explanation of badly adjusted and ill-spaced auto-inoculations to explain the high opsonic index in the acuter cases; fluctuating, it seemed in many cases to remain above the normal. Dr. Warrington considered the cases related by Sir James Barr of great value, and one which showed the value of the vaccine treatment as opposed to that of anti-bacterial sera. The latter had proved of little value in his practice.

Dr. G. A. Grace-Calvert, Dr. Nathan Raw, Dr. Yorke, Dr. Oram and Professor B. Moore also took part in the discussion.

In replying, Dr. BRADSHAW said that none of the speakers who had any experience of the method had controverted the main points of the paper. He was inclined to attribute the remarkable results of the anti-sera to a specific influence imminent in the blood of the horse.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, MAY 4TH, 1906.

The President, DR. LINDSAY STEVEN, in the Chair.

DR. JOSEPH N. GLAISTER read notes of two interesting cases of

CEREBRO-SPINAL FEVER

which had recently come under his observation in private practice. The patients were two sisters, one æt. 3, and the other æt. 6. The preliminary symptoms were ill-defined—feverishness, malaise being present. Then persistent vomiting followed with great restlessness. The head became sharply retracted, internal strabismus of the eyes became evident, and a tendency to coma revealed itself. Other symptoms present during the illness were tremors of both hands, contracted pupils, convulsive movements of arms and legs, a petechial eruption of the body, and incontinence of urine. Death was due to asthenia and coma. The temperature was not markedly elevated, although the pulse became very rapid during the later

stages of the disease. The diagnosis was verified bacteriologically by Dr. Robert Buchanan, by lumbar puncture, and the examination of a drop or two, which was thus obtained from the spinal canal. Film-preparations showed the specific micro-organism of Weichselbaum. It is a diplococcus found in the interior of the leucocytes, rather kidney-shaped, and not unlike the gonococcus. Cultures were made by Dr. Buchanan on glycerine agar and blood-serum. In twenty-four hours, a white growth appeared on the agar; that on the blood serum being whitish, dense and viscid. Prof. Glaister alluded to several cases that he had had occasion to investigate, and trusted the disease would be made a notifiable one, as he felt confident a number of such cases were not recognised in general practice.

Dr. ALEXANDER NAPIER communicated notes of AN UNUSUAL CASE OF TYPHOID FEVER

where the brunt of the disease had fallen upon the kidneys. The diagnosis in the early stage was difficult, owing to the absence of the usual and well ascertained signs, and symptoms. The President saw the case in consultation with Dr. Napier. An examination of the urine showed blood-corpuscles and the characteristic bacillus of typhoid fever.

The PRESIDENT (Dr. Steven) was inclined to the view that the case was one of hæmorrhagic nephritis followed by typhoid fever.

Dr. BROWNLEE, the Superintendent of Belvidere Hospital, had seen a number of cases where in some there was distinct nephritis present, with the usual casts in the urine. Another case with pus cells and blood corpuscles present in the urine, and in one case there was lobar pneumonia, the urine being bloody, with tailed epithelium in the urine, but no pus discovered.

In testing for blood in the urine, Dr. ALEXANDER NAPIER suggested the use of the plain tincture of guaiacum with the addition of acetic acid, as he had found it a more reliable method than the ammoniated tincture of guaiacum test.

GLASGOW NORTHERN MEDICAL SOCIETY.

MEETING HELD TUESDAY, MAY 1ST, 1906.

The President, DR. RITCHIE, [in]

DR. KAY read notes of a case of PNEUMOCOCCAL PERITONITIS

in a child. Dr. Kay said that the pneumococcus was now a well recognised cause of meningitis; but its power to set up peritonitis was not so generally known. If the peritonitis were diffused, the prognosis was bad; if it were encapsulated, the prognosis was good. The case he selected presented the characteristic symptoms of peritonitis, pain and tenderness, tympanitic abdomen, temp. 101·8°—a comparatively low temperature, respiration 38. He opened the abdomen and drew off 90 oz. of pus, and inserted two drainage tube. Temperature before operation was 102°F. and 99°F. after operation. The pus was examined and found to contain a pure culture of the pneumococcus. The child recovered.

Dr. A. J. CAMPBELL recorded a case which had a rapid termination. Pneumonia was present, followed by peritonitis. There was no cough or sputum. Pain was complained of in the left side of the head, followed by paralysis of the right side. This was thought to be due to embolism.

Dr. HOLME HENDERSON read an interesting and instructive paper on

ANÆSTHETICS.

He considered ether much safer to use than chloroform; and, if during an operation chloroform was giving trouble ether should be resorted to. It was a genuine stimulant to the heart. He alluded to the use of ethyl chloride. His main contention was that no one anæsthetic is universally the best, but discrimination

ought to be exercised in their choice, and great care in their administration. Dr. Henderson was of opinion that the deaths from the use of anæsthetics were much more numerous than was generally credited. In regard to methods of resuscitation; he laid stress on pulling out the tongue, artificial respiration and hot applications to the heart.

Dr. MACLACHLAN said that the late Professor George Buchanan was very fond of flicking a patient's chest with a wet towel, when the patient got into a bad state, and he considered that this was one of the best ways of rousing the respiratory centre. The head should be promptly lowered, or inversion of the body practised in those cases that got white in the face, and showed signs of death from heart failure. In the asphyxiated forms pulling the tongue out forcibly, with vigorous artificial respiration, seemed to be the best treatment. Dr. Maclachlan thought that chloroform should be given in drops at first, until one saw how the patient responded and then be pushed with care. He was of opinion once a patient was under chloroform no more should be given until slight signs of returning consciousness showed the patient could stand fresh inhalations, and thus the danger from chloroform poisoning would be averted.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, MAY 4TH, 1906.

The President, Mr. L. A. BIDWELL, F.R.C.S., in the Chair.

AN instructive discussion took place on

THE VARIETIES AND SEQUELÆ OF INFLUENZA.

Dr. SEYMOUR TAYLOR in opening the discussion said that in his view the multifarious forms which attacks of influenza took were mainly due to the differing soils which the micro-organism found in different patients. He was accustomed to group the cases under five types, namely, the neurotic, the pulmonary, the circulatory, the febrile, and the gastro-intestinal. The sequelæ he thought were, at least in some cases, dependent on a mixed infection, and any constitutionally weak spot in a patient was particularly liable to be the one affected.

Mr. BIDWELL remarked that as far as his experience went, particular epidemics seemed to be characterised by special types of the disease; he was especially interested in those cases in which acute abdominal disorder was sometimes very closely simulated. He also spoke of those cases in which bone or joint disease might follow as a sequela, probably these were due to secondary infection.

Dr. ARTHUR SAUNDERS agreed with Mr. Bidwell that varying types occurred in different epidemics. One of the most serious sequelæ in his experience was severe cardiac depression, which was generally accompanied with a very slow pulse, which might also be intermittent, the danger of syncope in such a condition was very great. In his opinion this state was due in part to affection of the vagus, and in part to a toxin directly acting on the heart muscle. The very marked general depression which was so frequently seen after an attack was, he believed, a combined result produced both from the nervous and circulatory systems.

Dr. RUFENACHT WALTER said that in the sanatorium with which he was connected they saw little influenza, and he attributed this to the open air conditions, for it was a not infrequent trouble in villages in the neighbourhood. No doubt a certain number of phthisis cases owed their commencement to the disease, and also some cases which were quiescent, were re-awakened by an attack.

Dr. CULVER JAMES spoke of certain cases of infective pneumonia which he had seen antecedent to the time of the recrudescence of influenza in an epidemic form

in this country; these he now believed to be of influenza origin.

Dr. STANLEY SMITH observed that it seemed to him that neuritis of various kinds was much more common since influenza was such a frequent affection, and he thought that these diseases were most probably related to one another as cause and effect.

Dr. LEONARD DOBSON also referred to the frequency of neuritis, especially of the musculo spiral nerve. In his experience this trouble was best met by treatment with high frequency electrical currents.

Dr. FURNISS POTTER spoke of the severity of those cases in which the middle ear, and then the mastoid, became affected, the amount of bone destruction which resulted being often extreme. This trouble was, however, rather a complication than a sequela.

Dr. W. A. BONNEY, Dr. H. W. CHAMBERS, Dr. KINSEY MORGAN, and Dr. F. G. LLOYD, having taken part in the debate, Dr. Seymour Taylor replied. There was a large attendance of members and visitors.

NORTH-EAST LONDON CLINICAL SOCIETY.

MEETING HELD THURSDAY, MAY 3RD, 1906.

Dr. G. ANGUS HUNT, Vice-President, in the Chair.

Dr. E. F. WILLOUGHBY opened a discussion on Asthma. After limiting the term to those attacks of intense dyspnoea, distinctly paroxysmal and spasmodic, occurring with or without recognisable cause or premonition at more or less regular intervals, often at the same hour, the patient's breathing during the interval being normal, the speaker proceeded to discuss the principal causes of the affection. He laid stress upon the condition of vaso-motor rhinitis, which so frequently preceded or accompanied asthma, and he considered that of all the intrinsic causes the most important appeared to be influenza. The immediate causation of an attack being some irritative disturbance of innervation, the treatment, apart from general and personal hygiene, had been mostly directed to the inhibition of the stimulation locally or through the nerve centres. The drug treatment of the attack itself and of the intervals between the attacks was then reviewed.

Since it was the personal experience of the reader of the paper that led him to choose this subject for the afternoon's discussion, Dr. Willoughby then described the symptoms, course and treatment of his own case, one of exceptional severity and interest. It was preceded by years of "hay-asthma," the essential cause being the poison of influenza, the exciting cause of a month of bronchial catarrh and violent paroxysmal cough, with dilatation of the right ventricle as a sequela. This latter had passed off completely, and only some pulmonary emphysema remained. All medical treatment had been useless, and he had consulted many eminent physicians and surgeons. After much prolonged suffering, the only things that gave him relief were hypodermic injections of morphine, deprecated by all his medical advisers, with inhalations of amyl nitrite or one or two drops of nitroglycerine *per os*. He took several sea-trips and a voyage to Madeira, during which time the attacks became fewer and of less severity, but they always yielded promptly to the injections. He was now quite free from any asthma, only a little shortness of breath at times being present. On no occasion did the morphia cause any sensations of drowsiness or nausea, its sole effect being in his case to arrest or prevent the attack.

Dr. E. MURRAY LESLIE thought that the value of a personal testimony like this was very great, and he wished that more medical men could be prevailed upon to describe their own illnesses with such accuracy of observation. He was a strong believer in the value of caffeine as a preventative of the attacks. The danger

of giving morphia had, he was sure, been over-exaggerated. The action of ethyl nitrite was more lasting, and therefore more useful, during the actual attack than that of amyl nitrite. He was glad to hear that it was possible for such a dangerous complication as dilatation of the heart to be completely recoverable from, and this fact would doubtless lead to some modification in the prognosis of the disease.

Mr. H. W. CARSON reviewed the surgical aspect of the question, more particularly from the standpoint of the intra-nasal treatment. He pointed out that there had been considerable prejudice in the minds of laryngologists and surgeons as to the possibility of effecting real cures by the removal of any source of nasal irritation, but he thought that the attitude of the profession was gradually changing with regard to the matter. He referred to the work of Mr. Francis who had collected a series of 600 cases of asthma in which intra-nasal treatment was adopted with 60 per cent. of successes. It was impossible to ignore these good results, and even if the method, in some cases, might seem to be empirical he thought that it was fully justified.

Dr. A. J. WHITING discussed the pathology of asthma and compared the typical attack to that of laryngismus stridulus. He thought that some cases were certainly of a purely nervous origin, while in others circulatory disturbances were an important pathological factor. He considered that the treatment by morphia was not without its risks, whereas the nitrites were always useful. The extract of grindelia had proved of considerable value in his hands.

Dr. H. ALEXANDER spoke of the benefits to be derived from the inhalation of chloroform, and he referred to one case in which only a single whiff acted like a charm in relieving the spasms. He had used nepenthe with success on several occasions.

Dr. NORMAN MEACHEN alluded to the curious relationship which existed between certain skin eruptions and asthma. He quoted the opinion of Trousseau to the effect that eczema might replace the asthmatic attack or be replaced by it, and he had himself seen this alternation in patients affected with true asthma.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

MEETING HELD FRIDAY, APRIL 27TH, 1906.

PROFESSOR A. FRASER in the Chair.

SLIDES ILLUSTRATING THE DEVELOPMENT OF FAT.

PROFESSOR D. J. COFFEY exhibited and described a series of slides which illustrated, in a striking manner, the development of fat in a young animal. A discussion followed, in which Professor Milroy and Dr. Rowlette took part.

SPECIMENS SHOWING THE CRANIAL DURA MATER EXPOSED FROM BELOW.

Professor SYMINGTON showed two specimens in which, after careful hardening of the parts in formalin, the base of the skull had been removed piecemeal, so as to exhibit the cranial dura mater from below. The relationships of the cranial nerves, of the Gasserian ganglion, and several other points were most clearly brought out.

The CHAIRMAN spoke of similar specimens which he had himself prepared before the introduction of formalin after injection of chloride of zinc solution.

BULK STAINING OF THE CENTRAL NERVOUS SYSTEM WITH THIONIN.

Professor MILROY described a method of staining portions of the central nervous system in bulk with thionin. The advantages of the method were explained by Professor Milroy, and the beautiful series of slides which he exhibited, clearly demonstrated the success of the method which he advocated.

CORRESPONDENCE. FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, May 15th, 1906.

NÆVI MATERNI.

SIMPLE cutaneous angioma, known under the name of *nævi materni*, or wine patches, are generally of congenital origin. In the majority of cases they are to be found on the neck or face. Frequently these spots disappear spontaneously a few months after birth, but at a more advanced age such a happy result can scarcely be hoped for.

If in themselves cases of angioma are by no means grave, they give rise sometimes to more or less serious complications, under the influence of some irritation and, more especially, traumatism. Consequently, the practitioner, when consulted for a simple angioma, should abstain from all active interference where the patient is under two years of age, while above that age, and even in adults, he should prescribe treatment only where the angioma was limited in extent.

Numerous have been the methods recommended in the treatment of angioma, but only three deserve mention: vaccination, electro-puncture, and caustics.

Inoculation of vaccine enjoyed, and continues to enjoy, considerable vogue amongst the public more than with the doctors. Frequently these latter are solicited by mothers to employ this method to remove the disfiguring spots. These inoculations had the double advantage of being sometimes efficacious, and always inoffensive. But the success is subject to two conditions: first, they should be practised on a child which had not been already vaccinated, and, secondly, they should be made around the spots, and not on them, otherwise hæmorrhage would be provoked, which would sweep away the vaccine.

Electro-puncture was employed for the first time by Ciniselli half a century ago and has numerous partisans. It consists in pressing through the angioma a current from a battery which decomposes the tissues in its passage, sets free the acids which go to the positive pole, producing the formation of a dry slough which is slow in becoming detached; the alkaline bases go to the negative pole where they provoke the formation of a soft clot when the electrode is pushed into the tissues. The methods used are of two kinds, positive monopuncture and bipolar electro-puncture; the first is represented by a metallic plate of large dimensions, covered with moist chamois skin. This is the negative electrode. The positive electrode of the battery, represented by one or several platinum needles, is inserted into the tumour while the negative plate is applied at some distance from the angioma. Each seance last from 5 to 10 minutes, and where the wine stain is of considerable extent a large number of seances is necessary and frequently both patient and operator are discouraged before a complete cure is obtained. Besides, the passage of the current provokes considerable suffering, and in the case of children, anaesthetics might be necessary.

The other method was practised by Prof. Bergonié, of Bordeaux. Its principal advantage was the limiting of the electrolytic action to the space comprised between the two poles, and by this means the painful manifestations are suppressed and the duration of the treatment much abridged, as stronger currents could be employed.

Yet, in a recent communication, Prof. Bergonié confessed that electrolysis was a complete failure. "The treatment of angioma," he said, "was the most difficult and the most delicate that can be undertaken. For my part, I have tried electrolysis under every form and the length of the treatment wearied both patient and operator." Consequently, Prof. Bergonié renounced electrolysis.

Applications of caustics are condemned by all contemporaneous authors who have written on the treatment of *nævi*, on account of the impossibility of

limiting their action, and the consequent disfiguring cicatrix. However, a German professor recommends a method based on the employment of chloride of zinc, and of which he speaks wonders. By this method Neumann treated with success over 700 patients.

A band of sticking-plaster, with a hole cut in it corresponding to the region, is applied to the angioma, and thus the neighbouring parts are protected against the contact of the caustic preparation, which is as follows:—

Chloride of zinc, 1-5 drachm ;
Elastic collodion (strong), 4 ounces.

The mixture should be well shaken before being applied with a pencil.

The hole in the plaster should be a little less than the dimensions of the surface about to be destroyed. As soon as the collodion has hardened, the parts are covered with gauze and maintained by means of a few straps of adhesive plaster. The next day or the following the dressing is removed, and instead of the red or bluish stain of the angioma necrosis of the region is observed, surrounded by an inflammatory zone ; but on the third day this zone has disappeared, and after another dressing the slough is allowed to eliminate of itself, which generally arrives on the seventh day. A simple dressing is then applied every two or three days, and the wound cicatrises rapidly.

In case that any part of the angioma escaped the action of the chloride of zinc, Neumann applies the following ointment:—

Arsenious acid, 1 drachm ;
Precipitated sulphur, 1 drachm ;
Spermacetic ointment, 4 ounces.

The dressing should be removed after two or three days, and the mortified parts removed with some blunt instrument, and an antiseptic dressing applied.

M. Neumann avoids, however, as much as possible the arsenical applications, as they provoke pain and are ill suited to children.

GERMANY.

Berlin, May 13th, 1906.

THE INFLUENCE OF TRAUMA ON THE ORIGIN OF CARCINOMA AND SARCOMA.

AN interesting contribution to this subject is made by Dr. Röpcke in the *Arch. f. Kl. Chir.*, B. 78, H. 2.

Interesting as it is it would have been much more so, and at the same time much more valuable, if traumata had been specially looked for in the case investigated, and if we could safely assume that they were absent in all cases in which their presence was not noted. In the earlier days over which the investigation carries us we may take it that the investigation was not pushed so far, and that it was in this respect incomplete. The investigation covers the years from 1889 to 1904, and embraces a total of nearly 800 cases of carcinoma and 189 of sarcoma. The investigation was for the purpose of ascertaining in how many of these cases there was evidence of antecedent injury. The number is not so great as would have been anticipated, but, as suggested above, the original notes may not have been so complete as could be wished.

As regards carcinoma of the lip, the use of a tobacco pipe was registered as the cause in 5 cases, a music pipe in one case, a sharp tooth in 2 cases, repeated cauterisation of a wart in 1 case, and 7 were attributed to a single trauma.

The most frequent cause of carcinoma of the mouth and nasal cavities was sharp edged and carious teeth. It was so 5 times out of 16 cases of carcinoma of the tongue ; 5 times in 11 cases of carcinoma of the buccal mucous membrane ; 11 times in 18 cases of carcinoma of the jaw. A carcinoma of the parotid gland developed on a cicatrix, a carcinoma of the nasal septum on the cicatrix of a syphilitic ulcer. Cancers of the face and scalp were frequently preceded by seborrhœa senilis, warts and atheromata.

In carcinoma of the stomach and intestines previous chronic irritations were spoken of as significant. Gall stones were found in 12 cases of carcinoma of the liver.

In mammary cancer the disease was attributed in one case to mastitis, 6 times to anomalies of development, twice to chronic irritations, and 8 times to acute trauma. Cancer of the bladder was met with twice in cases of vesical calculi, and once complicating a case of non-malignant papilloma. Cancer of the urethra developed in one case as a sequence of a congenital narrowing of the urethral orifice, in another case as a result of a sharp edged stricture. Carcinoma of the extremities developed in 3 cases after chronic inflammations and once after a naevus.

Nasal sarcoma developed in 2 cases from polypi, sarcoma of the cheek once in a pediculated fibroma and once from a birth mark. A melano-sarcoma of the palate arose from an ulcer caused by pressure of a dental plate, 4 cases of sarcoma of the jaw from connection with carious teeth, 2 sarcomata of the trunk from warts, one from a pediculated fibroma, and 3 after acute trauma. Sarcoma of the testicle, twice in undescended testicle and once in a case of hypertrophy. Sarcoma of the extremities occurred 17 times after a single trauma.

The writer concludes with justice that in the case of carcinoma chronic irritations are more likely to play a part, whilst in the case of sarcoma a single injury is more likely to be the exciting factor.

In 44 cases carcinoma occurred in the same family (descendants), in 7 of those cases the like organ was attacked, the stomach 5 times, the gall-bladder once, and the rectum once.

At the Society for Surgery, Hr. Krönlein introduced THE SURGERY OF GASTRIC ULCER for discussion.

He asserts in the first place that in a certain number of cases the ulcer was not amenable to medicinal or other internal treatment, although he made an attempt to prove the point on which the whole question of surgical interference hangs. As regards indications he adopts that put forward by Mikulicz in 1897 as still holding good. The surgical treatment of gastric ulcer comes into view when a consequent or repeated course of suitable treatment has had no, or only a transient, effect, and the patient's capacity for work or enjoyment of life is considerably encroached upon by it. The outward circumstances of the patient must also be considered. According to Leube permanent recovery took place in 75 per cent. in 400 cases reported by him ; very considerable improvement in nearly 25 per cent., so that the proportion of failures was very slight, and the mortality only 2.4 per cent. The permanent results in the collected cases of others had been much worse than this, Schultz, for instance, gave (after 6 months) good results 77 per cent., failures 15.2 per cent., died 7.6 per cent. or a total of failures of 23 per cent.

As regarded the mortality from operation it should not be above 8 to 10 per cent., and the late results would be excellent ; the only chance of mischief being development of carcinoma on the cicatrix (3 per cent.). Between the years 1887 and 1906 he had operated himself in 112 cases with a perfect result in 84. In estimating the permanent results he had only included the years up to 1904—72 cases, and of these 67 had been examined more recently, 41 were perfectly well, 16 had slight troubles, 8 were uncured, and 2 had died from complications. The diagnosis was always made correctly, the only doubt was as to whether an ulcer was still present or only its sequelæ—more particularly stenosis. In about half the cases the ulcer was single, in the other half there were more than one.

AUSTRIA.

Vienna, May 13th, 1906.

INFANTILE MORTALITY.

At the Meran meeting this subject was prominently brought before the members by Hutzler, who affirmed that the Hebammen were principally to blame for the very high death-rate among infants. On the slightest pretence of the mother's milk not agreeing with the child the mother is implored to take the infant from

the breast, which is usually accomplished without much regret, and fed with any kind of artificial food that this ignorant midwife may suggest. Escherich has given in his report that 16 per cent. of the cases in his own town have been proved to be due to this very source—atrophy and marasmus. Hutzler said he had devoted a considerable time to this subject in the children's hospital to which he was attached, and found in every one that the atrophic condition dated from the midwife's advice to separate the infant from the mother.

The question next arises, Who is to blame? The midwife is not educated in the feeding of children, but because she can separate the fœtus from the mother she presumes to know how to nurse the infant! This destruction of life goes on daily and nothing is heard of the circumstance until the infant is brought to an ambulatorium in a dying condition.

The blame rests on our system of educating "Hebammen," who are the principal advisers of these unfortunate women who have no medical attendant. These midwives, before being allowed to practise, should undergo a pædiatric training for a year and certainly not less than six months in the nursing of children, after which a searching examination.

Escherich reminded Hutzler that this regulation already existed in Austria but was ineffectual. It is not enough for these women to be under the control of a professional midwife, as their duties, or rather their assumed duties, went further. They should also be controlled by an expert in pædatrophy for the protection of the infant.

Schlossmann complained of the ignorance of our present class of Hebammen, who knew of nothing but soups and beef teas for infants, or some other more unsuitable article recommended by an enterprising commercial firm of advertisers.

Seltner thought these women should go through a course of clinical medicine, as no artificial food could be trusted to the supervision of the ignorant.

Huebner thought our text-books were largely to blame for leading these poor midwives astray. In many of them great stress is laid on syphilitic women sucking their own offspring. With this dicta in their mind, we cannot wonder at the result. Again, early clinical advice is easily obtained in large towns, but in the country this is difficult, if not impossible, in many cases. It is therefore a necessity to have the midwives better educated and their text-books revised.

Kamerer thinks every midwife should pass through a course in a hospital for children.

MILK FAT SECRETION.

Engel introduced a discussion on the physiological secretion of milk. How much came from the mother's food direct. How much from her own body? It was true the fat came directly from cells thrown off in the lacteal gland, and with Hubel's iodine the quantity of fat taken into the stomach and passed from the gland might be estimated. If a portion of sesame oil be taken by the mouth it will be passed through the lacteal gland in three to four hours and will continue 24 to 44 hours after. He considered the mother's diet a potent factor in the feeding of children. Many substances pass easily through the gland.

Meyer thought this test fallacious, as farmers have proved. The iodipin is split up in its mutations and cannot be estimated.

Schlossmann thought there was a difference of results in the Herbivorous and Omnivorous. It is well-known that a breakfast rich in fat will increase the milk.

THE Drapers' Company have sent a cheque for £10,000 to the fund for the removal of King's College Hospital to South London. An appeal was made to the public for the sum of £300,000 in order to effect the removal of this hospital. The Drapers' Company generously promised £5,000 conditionally on the rest of the sum required being raised by the end of 1904; this promise was afterwards increased by another £5,000, and the time limit extended to the end of 1905.

FROM OUR SPECIAL CORRESPONDENTS AT HOME. SCOTLAND.

SCOTTISH POOR-LAW MEDICAL OFFICERS.—A deputation of the Scottish Poor-law Medical Officers' Association, consisting of Dr. Muir, President, Dr. Campbell, Dr. Parkinson, chairman of the Public Health and Poor-law Committee of the British Medical Association, and Dr. Whittaker, waited on the Secretary for Scotland at Westminster on the 8th inst., with reference to the position of Scottish Poor-law medical officers. Dr. Muir stated the case of the deputation. Poor-law medical officers, he said, were subject to a number of grievances which they wished to be remedied by legislation. In the first place they desired to have an appeal to the Local Government Board in case of unjust dismissal, there being many cases in which parish councils, who, particularly in the Highlands and Islands, were intellectually and socially unfit to be entrusted with absolute powers, had harshly and unreasonably dismissed their medical officers for causes other than professional incompetence, sometimes from personal animosity, or from medical officers refusing to comply with orders which were not connected with their duties as servants of the parish council, and which in some cases might have led to the medical officer being struck off the Register. The deputation further claimed the right to order invalid diet for paupers without appeal to the Inspector of Poor, who at present had the power of veto. In the next place, they urged that power should be given to erect from parochial funds dwelling houses for medical officers, as at present in many places suitable residences were unavailable. They also contended that a suitable annual holiday, with allowance for a *locum tenens* at the rate of four guineas per week, should be granted. They also asked that a uniform fee of 21s. should be paid for granting a lunacy certificate in place of the present diversity of fee; a special fee for long and difficult cases which they had to attend was also urged. They asked substantially, that they should be placed in the same position as Poor-law medical officers in England and Ireland. Dr. Parkinson said that the British Medical Association heartily backed up the demands which had been made. The Scottish medical officers did not ask that they should be protected against their own wrongdoing, but that they should be shielded from injustice or wrong on the part of other people.

Mr. Sinclair, the Secretary for Scotland, thanked the deputation, and said he had been greatly impressed by the statements they had made. While not coming under any specific pledge, he undertook to consult with the authorities of the Scottish Department on the subject of the complaints brought before him.

SCOTTISH VOLUNTEERS AMBULANCE TROPHY.—The competition for this trophy took place in the Drill Hall, Forrest Road, Edinburgh, on the 5th inst., before a large gathering of spectators who were drawn together to witness a contest in which teams from all over Scotland took part. At the conclusion of the examination it was announced that the trophy had been won by the 1st Lothian Bearer Coy., B Team, and it was accordingly presented to them by Lady Cranston. Of the eighteen teams who competed seven were from Edinburgh, four from Glasgow, two from Dundee, and one each from Hamilton, St. Andrews, Helensburgh, Inverness, and Haddington. The success of the occasion was to a large extent due to the careful preparations which had been made by Brigade Surgeon-Lieutenant Colonel A. D. Webster, S.M.O., 1st Lothian Brigade, President of the Scottish Volunteer Medical Officers' Association, Capt. A. Macdonald, commanding the 1st Bearer Coy., and to the able secretary of the Association, Captain C. B. Ker, 1st Lothian Bearer Coy. In the evening Surgeon-General Keogh, M.D., C.B., Director-General Army Medical Service, who had been present at the competition, was entertained to dinner by the Edinburgh Committee of the Association, and

in the course of a forcible speech urged the necessity of reorganising the volunteer medical service and placing it in the same relation to the volunteers as the R.A.M.C. does to the Army. Only by such a change could the service be of real value in mobilisation. The 1st Lothian Bearer Coy. might well form the nucleus of a field ambulance which could readily be officered by junior practitioners of medicine and surgery.

BELFAST.

PUBLIC HEALTH.—The recent agitation in reference to the health of the city culminated in a large and influential meeting held on Tuesday evening, May 8th, to consider the question. The meeting was summoned by the Belfast Citizens' Association, a body of recent formation, which has hitherto concerned itself chiefly with the economical working of the various public bodies, and now appears in a new light in advocating increased expenditure. The chief resolution was moved by Dr. Calwell, the president of the Ulster Medical Society, and seconded by Mr. Wm. Crawford, chairman of the Royal Victoria Hospital. It read as follows:—"That the alarmingly high death-rate of Belfast, especially from tuberculosis in its various forms, demands vigilant attention from the citizens, and vigorous action by the responsible authorities, and shows the urgency and imperative necessity that the City Council should secure the highest specialised professional skill and lengthened experience available in the United Kingdom for the oversight of our public health." In an able and vigorous speech Dr. Calwell claimed the right of freedom of speech and of legitimate criticism of the actions of those whom by our votes we had put in authority. While giving credit to the Public Health authorities for much good work done in the past, he maintained that the words of his resolution were justified, and that the death-rate was now alarmingly high. The question was no new one, for ten years ago a special committee of the Corporation was appointed to consider it, the death-rate being then 24.3. In 1902 we came seventy-seventh out of eighty-two large towns. In 1903 the same, and in 1904 we were 75th-77th out of eighty-two large towns, being equal to Hanley and St. Helens and only surpassed by Salford, Manchester, Wigan, Liverpool, and Dublin. A careful study of the death-rate from phthisis showed that in Belfast there was every reason to expect that proper measures would be followed by a fall of 2 per 1,000, which would mean a saving of 358 lives per annum. But if other forms of tuberculosis were included, these figures might at least be doubled, and he did not think he was guilty of exaggeration when he said that if tubercle were banished from Belfast a third of their hospital beds might be closed. After some remarks on the Belfast annual report for the past few years, and especially on what it left unsaid, Dr. Calwell said that he thought he had justified the statement that the death-rate was alarmingly high. He then dealt with the attitude of indifference displayed by such a large majority of the citizens towards those matters, emphasising the fact that no great improvement could be looked for till they took an intelligent interest in them. He did not think there was need to say much on the second part of the resolution. The care of public health was like any other business in life—the greater attention paid to it the greater would be the gain. But it was not for him to say what steps were to be taken to meet the various evils he had pointed out. He was not a skilled officer of health, and he did not know. But one piece of advice he could offer with the utmost confidence—"Get someone who can advise you, and who will, for his training, his experience, his skill, his reputation as a specialist in public health, command the respect of the Council, of the medical profession, and of the public. Do for the Public Health Department what you would have done for the Technical Institute, for the tramways, for the gas, and for the Electric Department."

Mr. John Murphy (Secretary of the Trades Council)

moved the second resolution, which was:—"That the impending resignation of the Medical Superintendent Officer of Health presents a unique opportunity to the City Council for the appointment of an experienced medical officer, possessed of the highest scientific knowledge and training in public health matters, and for such changes in the Public Health Department as may be required for carrying out necessary reforms, and this conference is of opinion that the City Council should take action accordingly."

The resignation of the Medical Officer of Health, Dr. Whitaker, was announced two days later, and it now remains to be seen whether the City Council will perpetrate their contemplated job, or whether they will be convinced that discretion is the better part of valour and climb down as gracefully as they can.

Mr. A. B. Mitchell, one of the surgeons to the Royal Victoria Hospital, Belfast, was last week operated upon for appendicitis by his colleague, Professor Sinclair. His progress since the operation has been quite satisfactory.

THE DARNELL CASE.—A circular has been sent to all members of the profession in Ulster, and to a very few in other parts, inviting subscriptions to a fund which has been started to assist Dr. Darnell in paying the expenses of the recent litigation in which he has been involved. It is stated in the circular that his out-of-pocket expenses will probably be about £800. The preliminary list of subscriptions amounts to nearly £150. The treasurers of the fund are Dr. Kidd, of Enniskillen, and Dr. Calwell, of Belfast, and the secretaries are Dr. Cecil Shaw, College Square, Belfast, and Dr. Thos. Houston, Great Victoria Street, Belfast.

LETTERS TO THE EDITOR.

UNIVERSITIES AND MEDICAL EDUCATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The discursive article from a correspondent on "University Education in Ireland" in your last week's issue, while it contains little that helps towards the solution of that difficult problem, raises some points of interest to those who care about medical education. I take it that your correspondent's main point is that medical training should be entirely dissociated from university education. In this contention I hardly see that he is much helped by his attempt to revive the dead hostilities of an obsolete controversy. Apart from that, however, your correspondent quite misses the meaning of the term education. He is of the opinion, apparently, that the medical curriculum in itself contains, or ought to contain, everything useful for the training of a medical man. It is possible that by diligent study of an ideal medical curriculum a man might become a competent practitioner, but it does not follow that he might not have been assisted, even in that aim, by a wider education. For education in the sense of training of a man's entire nature, the study of a wide range of things is necessary, and the limiting to a groove is fatal. It is not merely, however, in the "rather superficial knowledge of mathematics, Greek and Latin" that a university education is of value, though even that knowledge, being of subjects widely different from anatomy, pathology, and clinical medicine, has immense educative value. The "grouping-schools of medicine, law and engineering in a university"—a point which your correspondent despises, is of even greater importance. The chief value of university training is in the intercourse the student has with other students, and not merely others following the same pursuit, but more especially with those following widely different pursuits. In after life we are apt to become narrow through a lack of this intimate intercourse with men of various occupations. How much more so at the period of life when character is being formed! When the medical man has become a mere tradesman, when medicine and surgery have

descended from their position as learned and humane professions to become mere trades, then the contention of your correspondent will be true, and a university training will be not only useless, but harmful. In the meantime, while of course university study cannot be considered a part, much less an essential part, of the study necessary for a medical qualification, it is the most important adjunct such special study can have.

I am, Sir, yours truly,

CRITICUS.

QUACKERY AND GENERAL PRACTICE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The articles and correspondence on the subject of quackery which have been appearing in your valuable journal during the past few months must have proved of great interest to the majority of the profession. However personally affected by the popular readiness to accept any form of blatant fraud if advertised with sufficient pertinacity, the practitioner must look upon the public attitude towards scientific medicine more with a feeling of sorrow than of anger. It seems indeed that the suggestion made some time ago in your columns may be true; and that by injuring the public health, by aggravating simple diseases and creating chronic invalids, most of whom pass in the end into the hands of legitimate practitioners, quackery forms really a source of profit to the profession. Be this as it may, nothing is more certain than the fact that the man who is his own physician has a fool for a patient, and that the treatment of disease by nostrums based upon diagnosis formed by reading advertisements leads to a vast amount of suffering and misery, and often to death. That the profession is almost completely powerless to interfere seems also evident. It is impossible to convince the public that medical objection to quackery can be inspired by any save selfish motives, and, as you have pointed out, we have the whole newspaper press, headed by *The Times*, now against us. It is lamentable to observe the present conduct of that newspaper in encouraging a traffic which, as you have also shown, was formerly denounced in plain terms by it on every suitable occasion. I am an old subscriber to *The Times*, and am aware how honourably distinguished it used to be with regard to the purity of its advertising columns. This is now all over. I have before me the issues for the last few weeks. These contain samples of almost every class of quack advertisement, including those of unqualified pretenders who undertake to cure by miraculous means surgical lesions of purely mechanical character, and which as the smallest knowledge of their nature shows, cannot be dealt with except by elaborate operations. So long as *The Times*, and all the leading papers, including *Punch* and other organs which profess to devote themselves to exposure of humbug, gain an important percentage of their incomes from quack advertisements, so long will the evils you have exposed endure. At the present rate of progress, generations will have to pass before sufficient scientific knowledge has become diffused to enable the people to take care of themselves in this regard. In the meantime the blame and the shame lie upon the newspaper-press.

I am, Sir, yours truly,

May 10, 1906.

AN OBSCURE PRACTITIONER.

MR. BERNARD SHAW ON VIVISECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The public as a mass are virtually without any knowledge of science, and are completely in the dark as to what is meant by the term, "scientific research." In no department—least of all, probably, in physiology, do the public understand what are the means and methods adopted by workers in pursuit of truth. Unequipped with necessary fundamental knowledge, the bulk of the people are unable to appreciate a logical statement built upon and composed of demonstrable fact, they are unable to form an independent opinion of their own; and if they trouble themselves

at all about questions, in which an acquaintance with scientific methods and with science is called for, they are obliged almost blindly to adopt the views of those they regard as authorities. A cant cry, a catchword, a plausible sophism, any blatant falsehood thinly veiled iterated and reiterated with sufficient persistency, seems at last to sink into the minds of the ignorant and to become accepted as unquestionable truth. The assured success of any quack medicine, if sufficiently advertised, however grotesque the powers ascribed to it, affords the coarsest example of popular credulity. In Christian Science and other forms of occultism, such as esoteric Buddhism, we see other kinds of anti-scientific superstition fitted for acceptance by great sections of the public who, if intellectual, have never had sufficient intellectual training to enable them to distinguish between the sham and the real, between concrete facts and illusions of the senses. This being the condition of the popular mind, we need not wonder at the success of the various anti-scientific cults of the day, which are promoted either by sincere convinced fanatics, or by those who, inspired by less worthy motives, devote their lives to the promotion of their objects. We see anti-vaccination societies and antivivisection societies disposing of large incomes, gaining more and more support from the public, and likely in the end to have their way. The only method to prevent such a consummation seems to lie through an active opposition propaganda, but whether the scientific world will display a willingness to enter into the contest is perhaps doubtful. In the meantime, it remains easy for Mr. G. Bernard Shaw to find a large audience ready to listen with delight to speeches such as that to which he gave voice at the meeting last week. This speech will be read with disgust, if not with anger, by members of the profession whom it so foully slanders. No doubt such utterances must damage the profession. At the same time they must give rise to a vast amount of preventible suffering and misery, and on this ground it appears the duty of the profession to break the almost complete silence which it has hitherto maintained, in the face of such constant libellous insults and inuendoes.

I am, Sir, yours truly,

A COUNTRY PRACTITIONER.

REVIEWS OF BOOKS.

ATMOSPHERE AND CLIMATES. (a)

THIS is the first fasciculus of the comprehensive *Traité D'Hygiene* undertaken by Brouardel and Mosny and which with its score of separate parts promises to be an invaluable addition to medical literature, and a most practical and serviceable directory to all readers of the French language who are engaged in the various branches of hygiene.

In the present fasciculus Professor Courmont deals with the Atmosphere in all its various features; while Dr. Lesieur undertakes the sections on Climatology. The work is well designed and so far has been well executed. We shall await the following numbers with interest.

LANDMARKS AND SURFACE MARKINGS OF THE BODY. (b)

THE appearance of a second edition of this little book within a twelvemonth of its first publication is proof sufficient that it has adequately filled the gap which the author, in common with many others, recognised as existing in the series of text-books, which the medical student must master. The general form of the book is maintained (*i.e.*, it is a note-book containing in a more or less tabular form the surface

(a) "Atmosphere et Climates. Par Jules Courmont et Ch. Lesieur. Pp. 124, with coloured plates and 27 figures. Paris: J. B. Baillière et Fils, 1906.

(b) "Landmarks and Surface Markings of the Human Body." By Louis Bathe Rawling, F.R.C.S., Senior Demonstrator of Anatomy, St. Bartholomew's Hospital. Second Edition, London: H. K. Lewis 1905. With 31 Illustrations.

markings of the various viscera, muscles, nerves, &c., of the body), and a few additional facts have been added. Thus we notice the introduction of some pages on the surface markings of the perineum, and the information to be gained by rectal and vaginal examinations, while to the appendix has been added a table, compiled from Gray's Anatomy, of the dates of ossification of the epiphysis of the long bones. Some of the illustrations have been altered, and for the better, but we regret to notice that the figures representing the lower limbs have not been replaced by others taken from more muscular and less graceful individuals. To the necessity of such replacement we drew attention in our review of the first edition, and the retention of the figures we cannot but regard as a blemish in an otherwise admirable book.

GYNÆCOLOGICAL DIAGNOSIS. (a)

To write a book on gynæcological diagnosis which will appeal both to students and general practitioners one must have the experience which can only be acquired through much practice in teaching. When we consider that Dr. Henkel is first assistant to Professor Olshausen, and that his courses in gynæcological diagnosis are the most famous and most sought after in Berlin, both from the excellence of his teaching and the wealth of his material, we expected much from his book. That our expectations have been fulfilled must be our verdict. The book is written in simple, clear language, and the diagnosis, especially from the clinical point of view, is thoroughly worked out. The section on Carcinoma uteri is very good and does much to impress the importance and means of early diagnosis. Great care also has been expended on the uterine displacements and on extra-uterine pregnancy. The illustrations are numerous and the majority of them instructive. The arrangements of the different sections could be better, otherwise the book is excellent and one which must prove of the greatest assistance to its readers.

LITERARY NOTES.

A NEW edition (the fourth) of Sir Wm. Broadbent's text-book on "Diseases of the Heart" and a new edition of Mr. Ernest Clarke's "Errors of Accommodation and Refraction of the Eye" are announced for publication this week by Messrs. Baillière, Tindall and Cox.

MESSRS. CONSTABLE & Co. announce as in the press "Recent Advances in the Physiology of Digestion," by Prof. E. H. Starling, M.D., F.R.S., Jodrell Professor of Physiology. Mr. H. K. Lewis has recently published a second edition of Rawling's "Landmarks and Surface Markings of the Human Body," and Mr. Pentland a second edition of Cunningham's "Text-book of Anatomy."

A PAMPHLET on "Natural Ventilation" before us relates to the Municipality of Odessa, who are erecting a general hospital in that city. One does not expect to hear of any over-anxiety in Russia for moral or material ventilation, [but the authorities of this Institution, which will be one of the largest in that Empire, have at least determined to set an example, and the plans of "Natural Ventilation" of Messrs. Robt. Boyle and Son, of London, so well known and appreciated by the medical profession in this country, are being carried out in the new Odessa hospital.

We have received an interesting little book entitled "Lectures to Teachers on the Prevention of Infectious Diseases," by Dr. Wm. Berry, Medical Officer of Health for Wigan (Bristol: John Wright and Co. 6d. net.). These lectures, five in number, give brief descriptions of all the more important infectious diseases as well as a clear account of the process to be followed in disin-

fecting rooms and clothing. The statements made are clear and uniformly accurate. This booklet should be put into the hands of teachers, and medical officers of health may safely recommend it as an introduction to the subject for use in schools.

In a recently published book, "The Care of Infants," the writer gives some excellent advice to mothers on the feeding of their children which should do something towards stemming the tide of infant mortality, if ignorant mothers could be induced to read it. He points out that there are three available methods of feeding an infant: (1) Breast feeding by the mother; (2) combined feeding, that is, from the breast and artificial food; and (3) artificial feeding, where Mellin's food is employed with cow's milk. For hand-reared infants the food best adapted must fulfil the following conditions: it must contain substances which closely resemble the components of breast milk; the components must be in proper proportion and in a form suited to the simple conditions of digestion during infancy; the total quantity given during twenty-four hours must be such as to represent the nutritive value of the amount of breast milk which would, under ordinary conditions, be given in the same time. Three-fourths of the infants who die under the age of one year are those fed artificially, and most of these deaths are solely attributable to unsuitable food.

OBITUARY.

EUPHEMIA STOKER, L.R.C.S. & P.EDIN.

WE regret to record the death of Dr. Euphemia Stoker at a comparatively early age, at her residence at Hampstead, London. Deceased served through the recent campaign at the Cape with distinction. At the first annual dinner of the Scotch Diplomates Association she made a speech clad in the then newly-granted gown of the Edinburgh Royal College of Surgeons. Dr. Stoker, who had been a widow for several years, leaves one child. Amongst other spheres of usefulness deceased for several years acted as lecturer to the London County Council.

MATTHEW BAINES, M.D.

WE regret to announce the death of Dr. Matthew Baines, M.D., late Surgeon Lieutenant-Colonel, of the 1st Middlesex Royal Engineer Volunteers, at an advanced age. He was formerly assistant surgeon to the West London Eye Infirmary, and afterwards physician to St. Paul's Home, Sydney Street, and the Training Home, Wharfedale Street. For many years he served with the 1st Middlesex Royal Engineer Volunteers, retiring with the rank of Lieutenant-Colonel and with the Volunteer decoration. Dr. Baines was an Associate of King's College and a Knight of Grace of the Order of St. John of Jerusalem in England.

FRANK SAMUEL GOULDER, L.R.C.P., M.R.C.S., OF DUDLEY.

WE regret to record the death, on the 9th inst., of Mr. F. S. Goulder, who for twenty-five years was in practice in Dudley. Mr. Goulder studied at University College, London, whence he qualified L.R.C.P., M.R.C.S. in 1877. He went to Dudley thirty years ago to the Guest Hospital. He then went as assistant to Dr. Carr, of Cradley Heath, and after remaining there a few years he returned to Dudley and set up practice for himself. He was one of the hon. surgeons at both the Dudley Dispensary and the Guest Hospital, and at one period was churchwarden at the Dudley Parish Church. Mr. Goulder was fifty-one years of age.

JOHN CLARKE, M.D. ST. AND.

DR. JOHN CLARKE, formerly of Mayfair, London, died on the 8th inst., at the age of eighty-two. He was the younger son of Sir Charles Mansfield Clarke, Bart., M.D., who was physician to her Majesty Queen Adelaide, was born in 1823, and was an M.D., of St. Andrews and a Fellow of the Royal College of Physicians London-

(a) "Gynäkologische Diagnostik in Zwanglosen Vorträgen für Studierende und Aerzte," Von Dr. Max Henkell, Oberarzt an der Kgl. Universitäts-Frauenklinik und Privat-Dozent an der Universität, Berlin. (Berlin: S. Karger, 1905.)

MEDICAL NEWS IN BRIEF.

A Medical Divorce Case.

A CASE of an exceedingly unpleasant nature, in which proceedings for divorce were taken against a well-known and esteemed medical man, Dr. Coleman, Physician to the Richmond and Hardwicke Hospitals, Dublin, has been at hearing during the past week. The allegations made by his wife were of a most serious nature, and were entirely at variance with the high opinion held of Dr. Coleman by the profession in Dublin as a whole. Amongst these mention may be made of attempted poisoning, attempted administration of chloroform, attempts to frighten his wife into a miscarriage, and attempts to hypnotise her, besides other charges. Various medical men were examined during the hearing, two in support of the charge of hypnotising and others amongst whom may be mentioned Mr. Lentaigne, F.R.C.S., and Dr. Martin Dempsey in support of Dr. Coleman. A statement by the petitioner that the wife of a well-known surgeon had made a remark, which, had it been made, would have been a most serious reflection on Dr. Coleman's personal character was contradicted on oath by the lady who was said to have made it. Although it seemed that at one time the jury would have stopped the case, it was adjourned on Friday until Monday, when, after hearing lengthy speeches which lasted all day from the respective Counsel, the Judge summed up in the defendant's favour, and the jury returned on Tuesday a verdict for him. We offer our sincere congratulations to Dr. Coleman on his complete vindication from charges which, if proved, would have ruined his professional career, and at the same time desire to express our deep sympathy with him in the trouble through which he has passed.

Royal College of Surgeons in England.

An ordinary meeting of the Council was held at the College on Thursday last, May 10th, Mr. John Tweedy, F.R.C.S., President, in the chair. Surgeon-General Arthur Mudge Branfoot, C.I.E., President of the Medical Board at the India Office, and Mr. Herbert Mackay Ellis, R.N., Director-General of the Medical Department of the Navy, attended, and were admitted fellows of the College. The Jacksonian prize was presented to Mr. Reginald Cheyne Elmslie, F.R.C.S. Mr. Walter Burford Johnson, of St. Thomas's Hospital, was admitted as the first Begley Student. A report was received from Mr. J. Ward Cousins, in regard to the proceedings of the Central Midwives' Board during the past year, and the thanks of the Council were given to him for his services as the representative of the College on the Board. It was determined to hold a Fellows' subscription dinner in the College on Thursday, July 5th. The President reported that Professor Jensen was unable to visit England to receive the Walker Prize, but that the Hon. Sir Alan Johnstone, K.C.V.O., British Minister at Copenhagen, had undertaken to present the prize to him on behalf of the Council. Mr. Edmund Owen (Vice-President) and Dr. H. Timbrell Bulstrode were appointed representatives of the College on the General Organising Committee for the Second International Congress on School Hygiene to be held in London in August, 1907. In accordance with the recommendation of the Committee of Management of the two Royal Colleges, it was determined to add the Bexley, Horton and Manor Asylums to the list of Lunatic Asylums recognised by the Examining Board in England for Clinical Demonstrations in Lunacy.

Staff Appointments at Guy's Hospital.

At the General Court of Governors, held on Friday week the following promotions and appointments on the medical and surgical staff were made:—To be a consulting surgeon, Richard Clement Lucas, B.S., F.R.C.S.; consulting ophthalmic surgeon, Charles Higgins, F.R.C.S.; to be a surgeon, Louis Albert Dunn, M.S., F.R.C.S.; to be ophthalmic surgeons, Herbert Light-

foot Eason, M.D., M.S., and Arthur William Ormond, F.R.C.S.; to be an assistant surgeon, Robert Pugh Rowlands, M.S., F.R.C.S.; to be an assistant physician, Herbert Stanley French, M.D.

The report of the hospital for 1905 was formally approved, and ordered to be issued; it shows a year's work of unexampled magnitude, 8,626 persons having been accommodated in the wards, and 137,792 persons treated as out-patients. The appeal for funds, issued in March, 1905, resulted in £57,000 having been received or promised up to the end of the year, leaving a balance of £43,000 still urgently required to clear the hospital from debt on capital account, and a deficiency of £15,000 per annum in ordinary income to be made good year by year. It, moreover, appeared that, although no building improvements or extensions were now in progress, the provision of new out-patient departments, of separate wards for children, and the rebuilding of the old clinical house were matters which it was highly desirable should be taken in hand when funds became available for the purpose.

Royal Sanitary Institute

THE annual dinner of the Royal Sanitary Institute was held on Wednesday last in London. The Duke of Northumberland, the president, occupied the chair, and the company included Sir F. S. Powell, M.P., Colonel J. Lane Notter, R.A.M.C., Surgeon-General A. Keogh, C.B., Sir Aston Webb, R.A., Sir Lauder Brunton, and Sir Shirley Murphy. The chairman, in proposing the toast of "The King" said the institute had lately been taking a great deal of interest in the second International Congress on School Hygiene, and the King, who was the patron of the institute, had consented to become patron of the congress also. Surgeon-General Keogh, responding for "The Navy, Army, and Auxiliary Forces," proposed by Sir Lauder Brunton, alluded to the question of sanitation in war, and particularly to the water question. There should, he said, be a definite method of providing an army in the field with pure water. He had come to the conclusion that the system of boiling water by a field army was impossible, and he was in favour of the adoption of a system of filtration by means of the ordinary filtration in field water carts. He considered it was a disgrace that there should have been 40,000 cases of enteric fever in the South African war; and he did not think we were one bit more efficient in the treatment of disease in the Army than we were in 1899. But he believed that the water problem, with regard to a fighting army, was on the eve of solution.

Long Vacation Course at Cambridge University.

THIS year the work of the Long Vacation Course in Pathology, Public Health, and Pharmacology will be divided into three sections: (1) (for D.P.H. Students) commencing on Monday, June 25th, and (2) (for Junior Students of Medicine) and (3) (for Advanced Students, Medical Men, &c.), commencing on Monday, July 2nd. In addition to the foregoing arrangements, we are asked to announce that the series of short courses of lectures and demonstrations on Pharmacology (Bronchial Asthma, "Vasoconstriction," the Specific Actions of Drugs, &c.), Pathology (Inflammation, Immunity, Antitoxins and Antibodies, Food Poisoning, &c.), and a course by Dr. Nuttall on Protozoal Diseases will be repeated this year. These courses will be open to medical men and senior students only; they will be held if a class of ten can be formed, and will not extend over more than four weeks. Particulars may be obtained on application to Mr. E. E. Stubbings, Pathological Department, New Medical School, Cambridge.

THE South London Institute for the Blind, the foundation stone of which will be laid on the 24th inst. by the Duke of Argyll, was founded in 1870 by the late James Hampton, "the blind man's friend," in Webber Row, S.E., in conjunction with the late Earl Shaftes-

bury, K.G., and the late Rev. C. H. Spurgeon. Since 1870 (thirty-six years ago) the work of the institution has been carried on by the aid of voluntary contributions. The scope of the charity during the last few years has greatly increased, and the committee find that the temporary hall in Westminster Bridge Road is quite inadequate to cope with the work. They have therefore acquired from the Corporation of London a site in the Borough Road on which it is intended to erect a building, to be called the South London Institute for the Blind Poor. The committee of this excellent charity have completed the foundations of the new building, but have only a small sum in hand, and they therefore make an urgent appeal for £2,500 to complete the new Institute and Home of Rest.

Legislation in Regard to Children.

THE Lord Mayor of London will open a conference at the Guildhall on Tuesday, the 22nd inst., convened by the International Congress for the Welfare and Protection of Children, for the purpose of considering pending legislation. Representatives of many important organisations throughout the kingdom will take part in the proceedings, over which Sir William Bousfield will preside. The first day's work will particularly refer to the methods of dealing with youthful offenders. A lively discussion is expected as to the free feeding of children in the elementary schools; Dr. Macnamara, M.P., and others, having promised to speak. The conference (of which Mr. W. G. Lewis, Barrister-at-Law, 8, Wells Street, Gray's Inn Road, W.C., is secretary) will discuss papers on "Remand Homes," "Children's Courts," and "Probation Officers," by Miss Adler, Miss Baker, Mr. Courtenay Lord, J.P., and a Report on "The Present Position of the Probation System in the United States," by Mrs. Ada Eliot Sheffield. Papers on "The Free Feeding of Children in Elementary Schools" will be read by Sir Charles A. Elliott, K. C.S.I., and Miss Margaret Frere. M. Marcel Kleine will describe the "Cantines Scolaires" of Paris. The discussion will be opened by Dr. Macnamara, M.P., and Sir Arthur Clay, Bart.

PASS LISTS.

Royal College of Surgeons, England.

THE following 102 candidates, whose names are arranged alphabetically, having previously passed the necessary examinations received their diplomas as members of the college on Thursday, May 10th:—Charles B. M. Aldridge, Gervase D. Alexander, G. Hely-Hutchinson Almond, John S. Austin, Arthur S. B. Bankart, George N. Bartlett, Stanley J. A. Beale, Edwin Beaton, William Beck, Claude J. E. Bennett, Frank C. H. Bennett, Charles M. Bernays, John B. Binns, Rowland A. Bowling, Samuel J. Boyd, John H. R. Brodrecht, John Horace, G. Brown, Ralph Brown, Oliver Bruce, Arthur S. Burgess, Percival Butler, Herbert Charles, Wm. W. D. Chilcott, John Clarke, William J. Cowan, Duncan Davidson, Edwin T. H. Davies, Robert Davies-Colley, Edmund M. Dolan, John J. W. Evans, Harold W. Farebrother, Richard V. Favell, Stephen Field, C. Fletcher, John R. Foster, Claud F. Fothergill, Elliott T. Glenny, Horace Gooch, Charles W. Greene, Reginald A. Greeves, Alfred H. Hardcastle, Raymond S. Harper, Percy B. Harrison, Arthur Hawkins, George M. W. Hodges, Cyril J. R. Hoffmeister, Richard Holtby, Ernest T. C. Hughes, Cyril H. T. Ilcct, Harold M. Inman, William A. James, Francis S. Jones, Thomas J. Latham, T. St. Leger Leyshon, Arthur R. Littlejohn, John McAsh, Charles M. MacLean, Ivan C. Maclean, Neil J. McLean, Eugene A. Mascarenhas, George P. Mills, Arthur Mülberger, Hubert C. Mulkern, John O. Musson, Arthur H. Norris, James J. Paterson, Patrick H. H. Pereira, Arthur R. Phelps, Harry G. Phippen, Philip A. Reckless, James E. H. Roberts, Felix S. Rood, Alfred M. Roome, Sidney J. Rowntree, Donald W. Roy, Albert Salmon, Douglas R. C. Shepherd, James Smalley, Hoyland Smith, James E. Smith, Leslie E. M. Smith, Henry S. Souttar, John H. Spencer, C. Stanley Clarke, Wm. J. E. Stuttaford, George W.

Sudlow, Alfred K. B. R. W. Taylor, Arthur G. J. Thompson, George S. Thompson, Henry L. Tidy, Joseph F. Trewby, T. Turner, Henry F. Vandermin, Guy T. Verry, Harold S. Vivian, Geoffrey Wachter, Maneck D. Wadia, Harold R. S. Walford, John Wallace, Howard F. Warner, Edward Wight, Edwin J. Wyler.

The Royal University of Ireland.

THE Senate met on Friday, May 4th, 1906, at 11.30 a.m. The results of the recent Spring Medical examinations were considered and awards made. The election by Convocation of Dr. John Campbell, M.A., was reported, and he was elected a member of the Medical Committee. The following resolution was adopted unanimously:—"That, having regard to the official pronouncement made in the House of Commons, on March 15th, by the Chief Secretary, that his Majesty's Government had been advised 'that the Senate of the Royal University of Ireland had the power to maintain order and to take all steps necessary to that end,' the Senate hereby direct the Standing Committee to prepare a draft of such statutes and regulations as shall provide the necessary means to enforce academic discipline and to punish academic misconduct." In reference to the disorder last October, it was directed that the minutes of the Senate meetings, &c., relating thereto be supplied to the Government. A meeting of the University was held afterwards at which the following awards were announced and degrees conferred:—

Second Examination in Medicine.—First-class Honours and a First-class Exhibition of £25, James M. O'Connor, Catholic University School of Medicine.

Third Examination in Medicine.—First-class Honours and a First-class Exhibition of £30, William D. O'Kelly, Catholic University School of Medicine; Second-class Honours and a Second-class Exhibition of £20, Marshall F. Huston, Queen's College, Belfast.

M.B., B.Ch., B.A.O. Degrees Examination.—First-class Honours in Medicine, Second-class Honours in Surgery and Midwifery, and a First-class Exhibition of £40, Robert Jamieson, Queen's College, Belfast; Second-class Honours in Medicine and Midwifery, and a Second-class Exhibition of £25, William J. Leighton, Queen's College, Belfast; First-class Honours in Medicine, and Second-class honours in Surgery, William A. McKee, B.A., Queen's College, Belfast.

Conjoint Examinations in Ireland.

Fourth Professional Examination.—Candidates who have passed this examination are:—John J. Hogan, with Honours; Charles J. D. Bergin, John Corboy, Reginald C. Galgey, Maurice R. J. Hayes, Henry M. Harrison, Daniel Hampson, Thomas Leonard, Leonard Lucas, Francis G. McCaughey, Robert M'Elroy, Patrick J. Rooney, William Sammon, George Sheppard, Sidney W. Talbot, George F. Wright, William G. Wright.

Army Medical Service.

AN examination of candidates for not less than forty commissions in the Royal Army Medical Corps will be held in London on July 26th and following days. Applications to compete should be made to the Secretary, War Office, 68, Victoria Street, not later than July 16, on which date the list will be closed.

MR. JOSEPH MILNTHORPE, J.P., of Bishopsdale Buxton, a well-known philanthropist, whose will has been proved at £88,375, after leaving bequests to his family and friends, has left the ultimate residue of his estate in equal shares to the following institutions:—The Sheffield Royal Hospital, the Sheffield Royal Infirmary, the Sheffield Jessop Hospital for Women, the Sheffield Children's Hospital, the Sheffield Deakin Institution, the Sheffield Institution for the Blind, the Manchester Royal Infirmary, Dr. Barnardo's Homes for Homeless and Destitute Children, and the Children's Home and Orphanage, Bonner Road, London, founded by Dr. T. B. Stevenson. These institutions seem likely to benefit by a sum of probably more than £60,000.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially Compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT LITERATURE OF PHYSIOLOGY AND PATHOLOGY.

Radium and the Virus of Rabies.—Danysz (*Annales de l'Institut Pasteur*, March 25th, 1906) traverses briefly but forcibly the conclusions of Tizzoni and Bougiovanni that the action of radium on the virus of rabies converts it into a vaccine, and that by making the rays of radium play on the eye one can cure rabies in a rabbit. Danysz exposed an emulsion of virulent spinal cord for twenty hours to the rays of 20 milligrammes of pure bromide of radium, and then inoculated rabbits. The inoculated animals died as soon as the controls. Further experiments showed that radium exerted no appreciable influence on the virulence of infective material. As regards the treatment of rabies by radium applied to the eye, Danysz is equally at variance with Tizzoni and Bougiovanni. Not only has radium, in his opinion, no curative action when thus employed, but it produces most serious lesions of the eye itself, ulceration of the lids, conjunctivitis with muco-purulent secretion, interstitial keratitis, congestion of the iris, and finally atrophy of the optic nerve. R.

Bacteriology of a Common Cold.—Benham (*British Medical Journal*, May 5th, 1906) reports his bacteriologic investigations in 21 cases of mild "common cold." He notes the scanty nature of all observations on the subject, the principal organisms previously noted being (1) *micrococcus catarrhalis*, described by Lord, De Jong, Dunn and Gordon, and others; and (2) the *bacillus coryzae segmentosus*, discovered by Cautley, and also observed by Gordon and probably by White. Benham's examinations were made on both the nose and throat and out of the 21 cases examined, he found organisms as follows:—a—(1) in 20 cases a diphtheroid organism; (2) in 10 cases, cocci negative to Gram's method of staining; (3) in 14 cases, cocci positive to Gram's method. Other organisms were found in small numbers, in much the same proportions as in normal noses and throats. (1) The diphtheroid bacillus is described in some detail and is believed to be identical with the bacillus described by Cautley. It grows easily on agar, on ascitic agar, and on nutrose-ascitic-agar, with difficulty on gelatine; the colonies are minute and circular. It has a slight tendency toward the formation of acid in carbohydrate media. It stains easily and by Gram's method; it is negative to Neisser's stain. It is a short bacillus, with rounded ends, in early cultures resembling a coccus, in later becoming cuneiform or club-shaped. It stains deeply at the ends, more faintly in the middle, so that it often resembles a diplococcus. (2) The cocci negative to Gram's method presented the features described by Dunn and Gordon as belonging to the *micrococcus catarrhalis*. It grows slowly and with uncertainty on ordinary media, and is easily overpowered by the common cocci. (3) The cocci positive to Gram's method were probably many of them pneumococci. They were always scanty, and the author did not succeed in isolating any of them. Benham concludes that the diphtheroid bacillus is probably causally connected with a cold, at any rate as affecting the throat, while the action of the micrococcus requires further study before any statement can be made. R.

An Antityphoid Serum.—Macfadyen publishes (*Brit. Med. Journ.*, April 21st, 1906) an account of successful experiments in the production of any antityphoid serum. He first separated endocellular toxins by a method previously described, viz., grinding live bacilli at the temperature of liquid air, and then extracting with dilute caustic potash. In this way a sterile bal-toxic fluid can be obtained. A goat was then injected with a very small dose (1-20 c.cm.) of

the juice, and at intervals of a week or more injected with gradually increasing doses. The animal's serum developed antitoxic agglutinative, and bacteriolytic properties. So high did the antitoxic power rise that 1-50 c.cm. of the serum was sufficient to neutralise 30 lethal doses (for the rabbit) of the endotoxin. The serum acted when injected simultaneously with, but separately from, the toxin; it also acted when injected at the onset of toxic symptoms. The investigation is one of great promise, since there is no reason to believe that such a serum should not have similar antitoxic properties in man to those demonstrated by Macfadyen in the rabbit. R.

Bacteriology of Summer Diarrhoea of Infants.—Morgan (*Brit. Med. Journ.*, April 21st, 1906) reports the results of a laborious bacteriological investigation into some 58 cases of infantile diarrhoea occurring in London. Up to the present most work on this subject has been done in America, and the association of two different organisms—the Saiga bacillus and the Flexner bacillus—with the disease has been definitely established. In Morgan's researches neither of these organisms was encountered, though in seven cases an organism presenting certain resemblances to Flexner's bacillus occurred. In 28 cases, however, one organism was found, which appears to have had a causal significance. Feeding with it proved quickly fatal to young rats and young rabbits, death being preceded by violent diarrhoea. The bacilli were recovered in every case from the spleen, and in a few cases from the heart-blood as well. On the other hand, injected intravenously and intra-peritoneally, this bacillus had no pathogenic effect. The filtrate, however, from a broth culture had a highly toxic action when injected intravenously. Morphologically the bacillus is a little smaller than the typhoid bacillus, multi-flagellated, and motile. Morgan can find no previous record of this organism, nor did Houston in extensive examinations of faeces, sewage and water, ever meet with it. The other organisms isolated and described by Morgan do not appear to be of importance. The interest of the investigation is in the suggestion that infantile diarrhoea occurring in this country may have a very different bacteriological causation from the parallel disease in the States. R.

Pathology of Rabies.—Frothingham (*Journal of Medical Research*, April, 1906) discusses the association with rabies of (1) the lesions described by Van Gebuchten as occurring in the ganglia, and of (2) Sargi bodies. The former change is typically a proliferation of the endothelial cells of the capsule of the ganglion cells going on to the destruction of the ganglion cells. This change Frothingham regards as invariably occurring in rabies, though it is possible that it also occurs in other conditions. The presence of Negri bodies on the other hand, i.e., the cell inclusions first described in 1902 by Negri, is only noticed in rabies, but is not noticed in every case of rabies. The author concludes that if Negri bodies be present, inoculation of animals is unnecessary as a diagnostic measure, while, on the other hand, if there be no lesions in the Gasserian ganglion, a negative report may be given. R.

Musculature of the Heart.—The *Johns Hopkins Hospital Bulletin* for April, 1906, contains a valuable review of the most recent researches on the musculature of the heart, contributed by Walter Baetger. Our knowledge of the arrangement of the muscle fibres in the heart wall dates, as he points out, from Ludwig's article in 1849, in which for the first time separate bundles of muscle fibres were recognised as existing. The next most valuable contribution was that of Krehl in 1891, in which the existence of a tendinous

band in the posterior aspect of the conus arteriosus was pointed out, thereby showing that three tendinous points exist at the base of the heart, the other two being the auriculo-ventricular rings. More recently MacCallum, by the study of semi-macerated embryonic hearts, has been able to more clearly trace the muscle fibre groups, and has divided them into main superficial and deep layers. The superficial fibres are further sub-divided into four muscles, the general course of which may be said to be a spiral one around almost the entire heart and crossing from one ventricle to the other. Each of these muscles takes origin from one of the tendinous points above referred to, and after a winding course terminates in one of the papillary muscles of the contra-lateral ventricle. The deep group of fibres is composed of three muscles, each of which describes an S-shaped course round the ventricles arising in a papillary muscle of one ventricle and being inserted in a papillary muscle of the other. In addition to the two main superficial and deep layers, certain intermediate fibres also exist which cannot be classified with the above, and which do not come into connection with the papillary muscles. They for the most part pass from the right into the left ventricle and form an important bond of union between the two chambers. M.

Circumscribed Abscesses of Bone.—Thomson contributes an important paper on Brochi's abscess of bone to the April number of the *Edin. Med. Journ.* He describes the lesion as being found in three different stages, namely (1) the quiescent form; (2) the ripe abscess; and (3) the abscess after it has ruptured and discharged externally. In the first stage a small cavity exists in the bone filled with serum and lined by a well defined membrane resembling the periosteum of young bones, and bounded externally by a layer of rapidly growing young bone. In the mature stage the cavity contains pus, and the lining membrane has become converted into granulation tissue, outside which the bone is being gradually eroded by the spread of the abscess. In the third stage the lining of the cavity reverts to the condition found in the quiescent stage, with the difference, however, that no new bone is being formed outside it. In discussing the cause of the transition from the first to the second stages, Thomson refuses to accept Gross's hypothesis that it is brought about by the physiological rarefaction that always succeeds sclerosis of bone, and inclines rather to the view that the change is caused by the virulence of the organisms present. Thomson also lays stress on the previous existence of an osteo-myelitis and in the long latent period that may intervene between such and the abscess formation. M.

The Pathology of General Paralysis.—Dr. Ford Robertson writes on his investigations into the pathology of general paralysis in the March number of the *Edinburgh Medical Journal* and gives a brief account of the facts which he has already made known in his Morison lectures. The writer has found that a diphtheroid bacillus is always to be found in the respiratory and gastro-intestinal tracts of general paralytics, and he supports the hypothesis that this organism is the main cause of all the nervous symptoms. The bacillus is not pathogenic to guinea-pigs, but proves fatal within ten days to rats, which animals develop nervous symptoms before death. The organisms have also proved fatal on injection into a goat. The animal became frantic, and its brain subsequently showed changes resembling those found in an early case of paralysis. The same diphtheroid organism has been obtained from the hair of ten general paralytics out of a total of twenty-four autopsies, and has been obtained from the blood of one case during life. The cerebro-spinal fluid, moreover, contains structures which resemble semi-dissolved Klebs-Löffler bacilli, while in two cases a culture of such bacilli has been grown from the fluid obtained by lumbar puncture. The last point in Dr. Robertson's chain of evidence is that the active polymorpho-nuclea

leucocytes of the general paralytic have, as a rule, a greater power of dissolving these diphtheroid bacilli than that possessed by the healthy leucocyte. This he regards as showing that to a certain extent some resistance is shown to the chronic toxæmia which he regards as causing the disease. M.

Etiology of Scurvy.—In the last few numbers of the *Sei-I-kwai Medical Journal* (Vol. xxiv., No. 10 and 12. Vol. xxv., No. I.) Professor Okada and Dr. Saito have published an account of an elaborate research which they have made into the etiology of scurvy. The main conclusion at which they arrive is that a micrococcus can be isolated from the blood of scorbutic patients, and this they believe to be the actual cause of the disease. In support of their belief they state (1) that the organism is readily agglutinated by the serum of patients suffering from scurvy, and even in dilutions of one hundred or more; (2) that the organism is pathogenic to animals, and produces in them symptoms somewhat resembling those of scurvy, namely, hæmorrhages in lungs and kidneys, loss of weight, hæmorrhage into muscles and general œdema. They have, moreover, in all fatal cases been able to obtain the cocci again from the heart blood of the inoculated animals. The cocci have been cultivated in most ordinary media, and both their cultural characteristics and their resisting power to heat and antiseptics have been worked out. M.

Suprarenal Diabetes.—Baron (*Russische Medicinische Rundschau*, No. ii., 1906) reports the results of his investigations into the glycosuria resulting from hypodermic injections of extracts of suprarenal glands. He has experimented on rabbits, guinea-pigs, dogs, and other animals, and has come to the following conclusions:—(1) Glycosuria invariably results from the hypodermic injection of suprarenal extracts. After a second injection the amount of sugar passed is less than after a first, but it is no less certain to appear. The intensity of the glycosuria largely depends on the state of the nutrition of the animal; (2) when a first injection is followed after some hours by a second, the sugar contents of the urine soon becomes diminished; (3) the glycosuria is always accompanied by glycaemia, and by increase of white and red blood corpuscles; (4) Suprarenal extracts diminish the general oxidation processes of the body and in this fact lies the probable explanation of the glycosuria produced; (5) suprarenal extracts given by the mouth do not produce glycosuria; (6) extracts of the suprarenal glands of such animals as have been previously treated by hypodermic injections of adrenalin, lose the property of producing glycosuria after injection into other animals. M.

Enterogenous Cyanosis.—Grutterink and Bergh describe cases of cyanosis in which investigation led to the conclusion that the symptom resulted from the absorption of toxic materials from the intestinal tract into the blood. In four cases, all of which were suffering from intestinal troubles, sulphohæmoglobin was found in the blood. In a second group of cases in which methæmoglobin was found in the blood, the clinical symptoms consisted of severe chronic enteritis, of long-continued headache, weakness of the limbs and general exhaustion. Absolute milk diet persisted in for twenty-four hours caused the cyanosis to lessen, but it returned again when the diet was altered. Examination of the fæces, urine and saliva did not reveal any cause for the methæmoglobinæmia, but in the blood nitrites were found to be present in large quantities within the red blood corpuscles. The authors think that the blood change is probably produced either by an increased production of nitrites in the intestines, or by an increased absorption through the diseased intestinal wall. M.

NOTE.—A summary will appear each week in the following sequence:—(1) "Recent Medical Literature." (2) "Recent Surgical Literature." (3) "Recent Gynecological and Obstetrical Literature." (4) "The Recent Literature of Physiology and Pathology."

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

MATER.—Cycling, of course in moderation, is, in our opinion, the next best form of exercise to walking in which healthy persons of middle age, and onwards, can indulge.

ROSS-SHIRE.—We cannot vouch for the report. It reached us through a private source, with the request that we should not deal with it without further confirmation.

A MEMBER.—The appointments of examiners at the college are entirely in the hands of the Council.

A MEDICAL PRACTITIONER (Gloucester).—We are obliged to our correspondent for forwarding the newspaper cutting.

K. M. (Exeter).—It would be obviously unwise to express any opinion as to the honesty of an applicant in his presence, any more than it would be in the matter of his health. The medical examiner must form his own conclusions upon both heads, but any resulting information is the property of the insurance company. In this particular case divulgence is clearly with consent of the person examined.

R.A.M.C.—The opsonic index can be ascertained only by experts who have command of the necessary material and apparatus. The method is too complicated in its present stage of development to come into general use.

Mr. J. BANISTER (Bromesbury).—Your communication came to hand as we were "at Press."

DR. R. R. R. (Liverpool).—See reply to Mr. Banister.

QUACKERY IN ADVERTISING.

Two correspondents have sent us (1) *The Christian Banner*, and (2) *The Church Family Newspaper*. If these may be taken as fair specimens of the religious papers generally, we can only wish that lay publications were as well conducted in regard to quack advertisements. In the latter we found but one announcement to which we might take exception, viz., *Phosferine*, "The remedy of Kings, supplied by Royal command to the Royal Family; a proven remedy for premature decay, rheumatism, hysteria." In *The Christian Banner* there were one or two others, such as *Mother Seigel's Syrup* and *Vita-Ore*, of which "thousands have pronounced it the marvel of the century for curing such diseases as rheumatism, gout, Bright's disease," &c. This latter, say the advertisers, has been highly commended by *The Lancet*, *The Edinburgh Medical Journal*, *The Medical Magazine*, and *The Clinical Journal*. This point we leave our contemporaries to fight. Our correspondents are thanked for sending these publications, which we are glad to acknowledge are exceptionally free of the usual run of quack cure-alls.

J. P. WILSON (Portsmouth).—The deaths from snake-bite in India amount from 18,000 to 20,000 or 22,000 yearly. This corresponds roughly to about 1 in 10,000 of population. The only way of combatting the evil at all effectually is by the extermination of poisonous snakes. Government is carrying on the process at the rate of from 200,000 to 600,000 annually.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MAY 16th.

ROYAL MICROSCOPICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Exhibition of Pond Life.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Dr. A. H. Tubby: Clinique. (Surgical). 5.15 p.m. Lecture—Dr. G. H. Savage: Dementia Præcox.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m. Operations. Dr. F. Taylor: Medicine. 3.15 p.m. Mr. M. Robson: Surgery. 4 p.m. Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 a.m. Surgical and Medical. 11 a.m. Eye.

THURSDAY, MAY 17th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m. Lecture—Dr. H. Campbell: Observations on Treatment.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m. Operations. Dr. G. Rankin: Medicine. 3.15 p.m. Sir W. Bennett: Surgery. 4 p.m. Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 a.m. Surgical and Medical. 12 noon. Ear and Throat.

FRIDAY, MAY 18th.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11 Chandos Street, Cavendish Square, W.).—5.30 p.m. Wightman Lecture: Dr. A. Broca (Paris): Appendicitis in Childhood.

EPIDEMIOLOGICAL SOCIETY (11 Chandos Street, Cavendish Square, W.).—8.30 p.m. Paper—Prof. R. Boyce (Liverpool): The Yellow Fever Epidemic in New Orleans in 1905.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Dr. D. Grant: Clinique. (Ear.)
LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m. Operations. Dr. R. Bradford: Medicine. 3.15 p.m. Mr. McGavin: Surgery. Out-patient Demonstrations:—10 a.m. Surgical and Medical. 12 noon. Skin.

SATURDAY, MAY 19th.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m. Operations. Out-patient Demonstrations:—10 a.m. Surgical and Medical. 11 a.m. Eye.

Vacancies.

Birkenhead Union.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments. Applications to John Carter, Clerk to the Guardians, Poor Law Offices, Birkenhead.

Birkenhead Borough Hospital.—Junior Resident House Surgeon. Salary £80 per annum. Applications to the Secretary.

Hants County Asylum.—Second Assistant Medical Officer. Salary £175 per annum, with furnished apartments, board, washing, and attendance. Applications to the Visiting Committee, Hants County Asylum, Fareham.

Killarney District Lunatic Asylum.—Assistant Medical Officer. Salary £100 per annum and allowances. Applications to E. W. Griffin, Resident Medical Superintendent. (See advt.)

Lancashire County Asylum, Winwick, Warrington.—Locum Tenens Medical Officer. Salary four guineas per week, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Leeds Tuberculosis Association.—Resident Medical Officer.—Salary £100 per annum, with board, lodging, and washing. Applications to Chas. H. Sedgwick, Secretary, 37 Great George Street, Leeds.

Portsmouth Borough Asylum.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Appointments.

AIKEN, ACHESON, L.R.C.P.I. and L.R.C.S.I. Dub., Certifying Factory Surgeon and Medical Officer Irvinestown Workhouse and Dispensary District.

BULKELEY, L. A. H., M.B., B.S. Durh., Junior House Physician at the Royal Infirmary, Newcastle-on-Tyne.

CARTER, F. BOLTON, M.I., M.S. Lond., F.R.C.S. Eng., Assistant Surgeon to the Leicester Infirmary.

CUNNINGHAM, H. B., M.B., B.S. Durh., House Surgeon at the Royal Infirmary, Newcastle-on-Tyne.

DICK, W., L.R.C.S., L.R.C.P., House Surgeon at the Children's Hospital, Bradford.

DUFF, DONALD, F.R.C.S. Edin., F.F.P.S. Glasg., Extra Dispensary Surgeon to the Glasgow Royal Infirmary.

HEUSTON, FRANCIS T., F.R.C.S.I., Surgeon to the Adelaide Hospital, a member of the Board of Governors of the Rotunda Hospital.

JONES, HERRESFORD, M.B., B.S. Durh., House Surgeon at the Royal Infirmary, Newcastle-on-Tyne.

LEE, H. F., M.B., M.C. Edin., Clinical Assistant to the Chelsea Hospital for Women.

LUNN, W. E. C., M.B., B.S. Durh., House Surgeon at the Royal Infirmary, Newcastle-on-Tyne.

SHAW, CHARLES J., M.B., M.R.C.P. Edin., Senior Assistant Medical Officer at the Royal Asylum, Sunnyside, Montrose.

WILLAN, R. J., M.B., B.S. Durh., House Surgeon at the Royal Infirmary, Newcastle-on-Tyne.

Births.

BENNETT.—On May 9th, at Staverton, 33 Vancouver Road, Forest Hill, London, the wife of Collin E. Bennett, M.R.C.S., L.R.C.P. Lond., of a son.

COOKE.—On May 8th, at 65 Abington Street, Northampton, the wife of A. W. Cooke, M.R.C.S., L.R.C.P., of a son.

GOLDIE.—On May 9th, at "Longcombe," 17 Harcourt Avenue, Southend-on-Sea, Essex, the wife of A. Evelyn Goldie, M.B., Ch.B. Edinburgh, of a son.

PORTER.—On May 9th, at the Limes, Berkhamsted, the wife of Charles R. Porter, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

RINGROSE.—On May 7th, at Lombard House, Newark-on-Trent, Notts, the wife of Ernest Ringrose, L.R.C.P. Lond., M.R.C.S. Eng., of a daughter.

STRACEY.—On April 23rd, at Sutton Bonington, Loughborough, the wife of Bernard Stracey, M.B., of a daughter.

Marriages.

GARDNER—SCRATCHLEY.—On May 10th at St. Michael's, Stockwell. Rev. Geo. Edward Gardner, M.A., of New Barnet, to Annie Rosalie Scratchley, widow of the late H. W. Scratchley, L.R.C.P., M.R.C.S. (née Norton).

WALKER—CUNLIFFE.—On April 17th, at Srinagar, Kashmir, by the Rev. A. L. H. Selwyn, Norman Duubar Walker, R.A.M.C., to Nora Dorothy, second daughter of Foster K. Cunliffe, Esq.

Deaths.

GOULDER.—On May 9th, at 74 Unthinks Road, Norwich, Frank Samuel Goulder, M.R.C.S., L.R.C.P. Lond., late of Dudley, aged 50.

MACLEOD.—On May 8th, at St. George's, Grenada, West Indies, Patrick Fletcher Macleod, M.D., I.S.O., aged 62.

STRACEY.—On May 10th, at Sutton Bonington, Loughborough, Jessie Mary, wife of Bernard Stracey, M.B.

WALLER.—On April 30th, in the wreck of the "Courier," of Sark. Frances Alice, aged 12, youngest daughter of Augustus D. Waller, M.D., LL.D., F.R.S., of 32 Grove End Road, London.

NOTES AND COMMENTS.

What the Lords Have Done.

LORD CREWE'S Bill, as it now stands, prohibits limited companies from carrying on the business of pharmaceutical chemists, or of chemists and druggists, unless they have the name of a registered qualified employee conspicuously displayed. His further proposal that companies were to be subject to the Pharmacy Acts as though they were individuals was rejected. The outcome of this rejection is that companies are entitled to use a description implying that they hold legal qualifications. It is difficult to realise the full extent of the danger to which the introduction of such a principle exposes the public. At one blow the whole fabric of protection of the interests of the community against unqualified or charlatan practice is demolished. If a state recognise legal qualification and pharmacy cannot be limited to those who have passed the necessary examinations, how can it be logically reserved for other special qualifications? Why, for instance, should not companies be permitted to practise law, just as freely as they may now perform the work of qualified chemists? So far as medicine is concerned, the present law is scandalously inadequate to prevent either companies or individuals from irregular practice to their hearts' content. What will the Lords say when medical men ask for protection similar to that they have now declined to grant to chemists?

The Chemists' War.

THE protest of the qualified chemists against the invasion of their calling by trading companies is based on principles of elementary justice. A fierce controversy is being waged by them in the public journals, Parliament, and on every other possible vantage ground. Their main contention appears to be that the term "chemist" applies simply to individuals, and cannot be legally employed as a loose general description tacked on to this, that, or the other trading company. They urge that the safety of the public, which is secured by the responsibility attached to individual qualification in pharmacy, is endangered when large commercial organisations are permitted to practise as chemists and to employ unqualified assistants. From the standpoint of the man-in-the-street that argument would be practically unanswerable. Those masterful capitalists, however, who dominate the chemist companies' enterprises, have

been able to secure an opposite opinion from the Lords. Will the individual chemists accept that verdict lying down?

When the Shoe Pinches.

It is all very well for the chemists to cry out when the shoe pinches. This experience, unpleasant as it is, should teach them the lesson that "live and let live" is a moral that must be applied all round, as well as to the individual case. We refer to the practice of counter prescribing, whereby an enormous injury is inflicted both upon the public and upon the medical profession. If, as the chemists argue, it is dangerous to the public to permit a pharmaceutically unqualified dispenser to make up physic and sell drugs, it is clearly a thousand times worse for a medically unqualified chemist to assume the function of a medical man. For the ancient and honourable craft of the chemist, as practised by its self-respecting members, we have a sincere respect. For the trespass upon legitimate medical practice, founded as it is upon a false assumption of special knowledge, we have nothing but condemnation. The chemists show themselves able to defend their rights. When will medical men unite for a similar purpose?

A Wise Suggestion.

THE recent action against a surgeon of a London special hospital and his house-surgeon raises a point of practical importance. The defendants appeared in the Court of King's Bench and denied liability for damages owing to their alleged negligence of the plaintiff. The facts, which do not appear to have been disputed, were that plaintiff underwent some uterine operation and that a pessary was inserted while she was still unconscious. The defendants allege she was told to return to the hospital in two months' time in order to have the instrument removed. The plaintiff denies that she was so instructed, and as a result the instrument was not discovered until some eighteen months afterwards, by which time she had sustained serious injury. The jury returned a verdict for defendants, adding a rider to the effect that they thought it desirable that in all such cases written instructions should be given to patients by the hospital authorities if they were required to return. With Mr. Justice Phillimore, we regard the suggestion as wise and prudent.

LEADING ARTICLE.

THE REDEMPTION OF THE INEBRIATE— VIDE "THE TIMES."

DURING the past few years we have published many letters from distinguished members of the profession, selected from a mass of correspondence, all couched in similar terms, protesting against the conduct of *The Times* in opening its columns to quack advertisements of a class formerly not to be found there. Not only were such advertisements excluded from that journal, but the whole system of medical quackery was on occasion exposed and vigorously denounced in editorial articles. *The Times* has now, it seems, taken up an entirely different attitude. In its advertising department it has adopted the motto *caveat emptor*; it leaves the ingenuous reader to take care of himself and shows itself willing for a consideration to publish any announcement, however deceptive or injurious to the public it may evidently be. Intense disgust has been excited during the past few weeks by the publication of a series of advertisements of the "Keeley Institute," headed "The Redemption of the Inebriate." These have been printed in the form now familiar to readers of *The Times*. In "double leaded" leader type they are inserted next to editorial matter, which as far as possible they are made to resemble, and prefixed is a note to the effect that "they have been written by a member of *The Times* advertising staff after thorough investigation, conducted with the assistance of an independent and registered medical practitioner of long experience." Short of editorial endorsement, these paid puffs, as they avowedly are, receive thus the approval and sanction of the leading journal. The concoctor of the puffs is, of course, not to be blamed; he has carried out his work as instructed in the way of business, and has done it uncommonly well. The literary quality of the puffs is superior, and accepting in good faith the information supplied, the writer is not to be blamed; it is the fault of his employers if they are calculated to mislead the public whilst casting gross slanderous and libellous imputations upon the medical profession. These effects are produced by an argument of which the transparent sophisms are evident to the instructed reader, but which is clever enough to satisfy or convince the simple public. The statements throughout are characterised by suppression of the truth and suggestion of the false. For instance, the fact is concealed that there is a commercial side to the "Institute," and that the patients are called upon to pay in advance twenty-four guineas for four weeks' treatment, whilst by the statement that the honorary committee are actuated by purely benevolent motives a false idea is suggested that the "Institute" is a purely philanthropic undertaking. If no commercial interests were at stake there could be no object in keeping secret any part of the method of treatment, and it would be at once fully disclosed for the benefit of suffering humanity.

Whatever pecuniary loss were incurred no true man of science would restrict the employment of so vast a boon; no medical practitioner could retain his professional position if he made of such a discovery a commercial speculation. It is, moreover, perfectly certain that he need not do so. The discoverer of a simple method of cure for drunkenness would rank among the greatest benefactors of mankind; wealth and honour, a monument in every civilised land, would surely be his. Seeing that drunkenness is not due to a single simple cause, and that the causation is extremely complex, being made up of many moral, physical and mental factors, no one with sufficient knowledge of the psychology and pathology of the inebriate could without rigid scientific proof accept a statement as to the efficacy of any advertised "cure." None of these cures is supported by evidence beyond the testimony of "grateful patients"—testimony of exactly the same kind and value as is put forth on behalf of all the new nostrums which enterprising manufacturers daily bring to the front. Drink cures all put forth claims not far short of the miraculous, and such claims being refuted by science and opposed to experience are treated with contempt by the mass of the profession. To suggest, as the puffs in question do suggest, that the hostility of medical men is due to some hard, selfish, and rigid code of etiquette is a gross calumny. There exists no written code of professional ethics, and everything in professional life is held to be subordinate to consideration of the welfare of the patient. To suggest that there exists a kind of conspiracy not only among practitioners but among the great body of scientific workers throughout the civilised world to ignore or suppress any method of treatment having the smallest claim to attention is to utter a baseless libel upon a great and honourable profession; and it is to this that *The Times* lends itself. It is possible that the new business methods adopted by the great journal may from the sordid point of view prove highly profitable, but we take leave to doubt whether in any higher sense of the word they will be found in the end to pay. It seems to us that the new departure involves degradation—degradation in which the high-minded, and eminent men who in the editorial columns are the daily preachers of private and public morality must share. They are at least knowingly deriving their incomes from funds gathered by their employers in part at least by unscrupulous if not shameful means.

ON reference to our "News" columns, it will be seen that the honorary gold medal of the Royal College of Surgeons of England was presented after the banquet on Friday last by the President to Lieutenant Colonel Sir Havelock Charles, I.M.S., K.C.V.O.

Society of Apothecaries of London.

THE following candidates, having passed the necessary examinations, have been granted the L.S.A. Diploma of the Society, entitling them to practice medicine, surgery, and midwifery:—J. W. Blooker, H. S. Chate, and F. J. Macphail.

NOTES ON CURRENT TOPICS.

Anti-Typhoid Inoculation in the Army.

WE learn from our contemporary the *United Service Gazette* that the interim report of the Departmental Committee appointed to inquire into the subject of anti-typhoid inoculation in the Army will shortly be published, and that it will prove satisfactory to the medical profession. The Committee have held a series of six meetings, and have carefully studied the available statistical material, and their report will make a strong recommendation that the practice of voluntary inoculation against typhoid fever be resumed, since the records available up to date prove that the practice has resulted in a substantial reduction in the incidence of and death rate from enteric fever among the inoculated. It further appears from the report that, in addition to the loss to the State through sickness and invaliding, the loss from deaths alone amount to half a battalion in the year. We trust that the present Government will listen to its Departmental Committee, but we fear that it is only too likely that a Government which flirts—to use the mildest terms—with the anti-vaccinator, and likes to mistake his bleatings for the voice of experience, will turn a deaf ear to other forms of serum prophylaxis.

The Modern Nurse.

AT Queen's Square Club last week a paper was read by a lady named Miss Genn declaring "that Mrs. Gamp is preferable to the modern trained nurse." From the report before us we gather that this lady said that Mrs. Gamp's conversation compared favourably with the pert self-sufficiency of the modern trained nurse. The training of a nurse in these days destroyed the charm of women. The nurse became hardened, unsympathetic, cock-sure, and her only aim was to marry a medical student, or a desirable patient. A number of nurses were among the audience, and we trust that they recognised that a railing accusation of this kind defeats its own purpose. That modern nurses are not perfect is a failing that they share with all other classes of the community, and that some of them are unworthy of their high calling is consistent only with the known facts of the fallibility of human nature. But sweeping generalities such as those made are the result either of ignorance or prejudice, or both, and are as unbecoming as they are untrue. There are a certain number of women who blossom out into magazine articles on the faults of nurses at periodical intervals, and seem to delight in slandering a class of the most self-sacrificing and noble of their sex. Such diatribes find no echo in the hearts of medical men who are associated with nurses in their daily work, and are resented as cruel and unfounded

aspersions of a particularly odious kind. The person who prefers Mrs. Gamp with her drunken habits and her atrocious vulgarity to a modern nurse must be, as Mr. Mould said of the lady in question, "A woman who observes and reflects in an uncommon manner." We will forbear to finish the quotation.

The Prevention of Syphilis.

THE ardent votary of modern medical science looks forward with simple faith to the time when all communicable disease shall vanish from the face of the earth. The first great step towards that happy end in any given malady is usually—though by no means invariably—the discovery of its specific cause. Plague and cholera have been practically banished from the United Kingdom by improved hygiene, and there is little doubt that small-pox might be stamped out of existence by universal vaccination in conjunction with an efficient public health service, even in the absence of recognition of a specific pathogenic organism. The discovery of the bacillus of tuberculosis has been followed by a marked diminution of the disease, and a similar statement applies to enteric fever. Oddly enough, the identification of the organism of diphtheria has been followed by an increased incidence, doubtless due to the creation of a wider educational system. The most notable recent conquest of science in this direction has been the discovery of the *spirochæte pallida*, the casual relationship of which to syphilis may be accepted as reasonably demonstrated. At the last meeting of the Académie de Médecine in Paris, Professors Metchnikoff and Roux communicated a striking observation with regard to the prophylaxis of syphilis. By thirteen experiments upon monkeys they showed that the development of syphilis might be arrested by rubbing the site of inoculation with calomel ointment. A medical student then submitted himself for experiment and was inoculated with virus from two hard chancres. An hour later the site of inoculation was rubbed with calomel ointment, and three months later no sign of the disease was visible. Several monkeys inoculated at the same time either died or developed syphilis, whereas one macaque treated with calomel eight hours after inoculation escaped, and another twenty hours after inoculation developed a chancre. These experiments, while, perhaps, not absolutely conclusive, nevertheless open up a brilliant prospect in the campaign against one of the deadliest scourges of mankind.

The Poisons and Pharmacy Bill.

THIS Bill, which came before the House of Lords on the report stage, as a Government measure, on May 11th, has, by the adoption of an amendment proposed by Lord Ebury, been so modified that it no longer meets with the approval of the Pharmaceutical Society. Clause 4 of the Bill contained a proviso which, if carried, would
